The Mail Contracts.—The Government has been defeated in the Lower Chamber upon the question of the new mail contracts with the "Nederland" and Rotterdam "Lloyd" Steamboat Companies, as the Bill embodying those contracts—of which particulars were published in *Industries* (see Vol. IX., page 556)—was rejected by a small majority. Numerous members were of the opinion that the Government had not made such an advantageous bargain with the steamboat companies as it professed. They also opined that a period of fifteen years was too long for such contracts. The Ministers contended that a centralisation of the double service of steamers between Holland and Insulind, so as to obtain regular weekly sailings in the two directions, had become a necessity, especially in the face of the severe competition with foreign steamboat companies which draw increased and increasing State subsidies. The Government received a defeat, and the difficulty now will be how to deal with the matter before July 1st next, upon which date the present arrangements will come to an end.

New Exhibition.—In 1892 there is to be a second International Exhibition in Amsterdam of appliances to minimise dangers to life and limb in factories and workshops. The first one took place last year, and was a great success. It led to the establishment of a permanent association having the same objects in view.

Canadian Poplars in Holland.—The Dutch Society for the Reafforestation of Heaths has obtained a large supply of cuttings of Canadian poplars from North America, through the medium of the Dutch Consul-General at New York, for distribution among agriculturists generally. The twofold object is to reafforest heath, and to replace the native poplars which are being decimated by a strange disease, supposed to have its origin in the impoverishment of the soil.

STOCKHOLM, 7th February, 1891.

Present State of the Iron Market.—The dulness in the foreign iron markets still exists, and the difficulties besetting the industry in Sweden have not been overcome. Although the prices for coal and cokes are firm, the quotations for iron are weaker, and there is little inclination to buy at present. Foreign buyers are well stocked with pig iron, more so than with manufactured iron, but they are holding back. The following official base prices per ton are agreed upon:—

	F.o.b. Gothenburg.		F.o.b. Stockholm.
Ordinary hammered iron	£8 0 0	...	£8 0 0
Ordinary rolled iron	8 5 0	...	8 0 0
Fine rolled iron	8 15 0	...	8 10 0

The Production of Iron.—The comparatively young Society of Swedish Ironmasters bids fair to prove a useful institution, and its work has already resulted in bringing about a greater uniformity in prices and in the collection of some instructive statistics. These were laid before the first quarterly meeting this year, which took place at Orebro. The production during the last two years is given in the following tables:—

	1889.		1890.
Pig iron	421,176 tons.	...	435,522 tons.
Blooms	228,546 ,,	...	227,786 ,,
Bessemer ingots	80,614 ,,	...	92,247 ,,
Martin ingots	54,613 ,,	...	67,779 ,,

During the two years there have been in operation:—

	1889.		1890.
Blast furnaces	150	...	145
Furnaces	404	...	396
Bessemer converters	25	...	23
Martin works	23	...	26

The shipments during last year were as follows, as far as some of the more important articles are concerned, the figures for 1889 being added for comparison's sake:—

Digitized by Google

	1889. Tons.	1890. Tons.	During 1890. Decrease. Tons.	Increase. Tons.
Pig iron	79,175	59,931	19,244	—
Ingots	8,530	8,060	470	—
Blooms	16,596	12,991	2,605	—
Other hammered and rolled bars	200,244	185,468	14,776	—
Ends of bars	5,924	3,978	1,946	—
Wire iron	4,166	4,971	—	805
Plate iron	5,717	6,982	—	1,266
Nails	2,167	2,461	—	294

ANALYSIS OF STATISTICS.—A proportionate share of the decrease in exports affects the last quarter of 1890. The aggregate decline in the shipments of the above articles during 1890, as compared with 1889, amounts to 36,676 tons. Of this quantity pig iron accounts for 19,244 tons, and rolled and hammered bars for 14,776 tons. Considering the larger production of pig iron and the smaller export one might naturally expect the stocks of this commodity to show an increase. Such increase has, however, been considerably discounted by the much greater production of steel. The increase in the manufacture of steel during 1890 over that of 1889 amounts to an aggregate of 24,799 tons, of which 11,633 tons are Bessemer ingots and 13,166 tons are Martin ingots. With regard to warrants, there is a decrease of 1,813 tons, as compared with the figures at the end of last year.

STAFF OF THE SWEDISH STATE RAILWAYS.—The Swedish State Railways have a staff at their various offices of fifty-seven men, their aggregate pay amounting to 141,840kr. annually. The "line" section comprises 1,671 persons, and their annual pay amounts to 1,079,740kr. The traffic section consists of 2,847 persons, with an annual aggregate pay of 2,791,280kr. The machine section comprises 1,077 persons, with an annual pay of 1,213,060kr. Altogether, the Swedish State Railways have in their employ 5,652 persons, with an aggregate annual pay of 5,225,920kr.

CHRISTIANIA, 7th February, 1891.

TEXTILE INDUSTRIES.—The wool industries in Norway have, on the whole, done well during 1890, and not only have several new works been commenced, but many of the older establishments have been materially extended. The result of the increased production, and of the keener competition from Sweden, where the textile industry is advancing very rapidly, was a duller tendency in cloth goods during the latter part of the year. In consequence sales rather dragged, and some little time will elapse before trade finds its proper level. Many small mills, which are chiefly intended for local requirements, have done well during the past year. The cotton industry is steadily progressing, and, although no large installation has been completed during 1890, several of the existing establishments have extended their business. The import of cotton has been somewhat larger during 1890 than during the previous year. The export of cotton goods has been larger during last year than during the previous year; it takes place to Denmark only. A quantity of coloured goods have been exported to Sweden.

COPENHAGEN, 7th February, 1891.

WATER WORKS AT COPENHAGEN.—The important extension of the Copenhagen Water Works comprises more efficient arrangements for obtaining water, and will give additional pumping installations to the town. The supply of water from the Söndersö lake will be increased to 130,000 barrels per diem by means of new borings. Several of the old bore holes have collapsed through the destruction of the iron pipes from rust and wear and tear, so that the daily supply of water has been reduced to some 40,000 barrels. The new borings comprise eight holes, made to 6in. wrought-iron pipes, in which 4in. cast-iron pipes are inserted. This arrangement, which has been made with a view to durability, will probably yield a great increase of water at a moderate outlay, and will allow of further extensions. If these extensions should be largely increased, it will, however, be necessary to enlarge the pumping station at Söndersö, and to increase the capacity of the pipes from that place to the town.

CONTRACT FOR STEEL RAILS.—A contract which was given out last month for the supply of 5,790 tons of steel rails for the Danish State Railways has been secured by an English firm.

MADRID, 9th February, 1891.

IMPORTS AND EXPORTS OF ORES AND METALS.—According to the Custom House returns for 1890, the imports of coals from England were 1,444,174 tons, which shows an increase of 108,745 tons over the previous year. Of coke there were 276,814 tons imported, which shows a decrease of 2,330 tons. The total export of iron ores was 5,648,811 tons, or an increase of 597,198 tons. The export of pig iron amounted to 67,446 tons, and the imports were only 34,324 tons. The imports of wrought iron and steel amounted to 69,261 tons, or about one-half of the total quantity used, which is very small relatively to the population. The export of copper ore, which consists almost wholly of pyrites, was 680,277 tons, or a decrease or 118,000 tons, but this is compensated for by the export of 38,934 tons of copper as metal, most of which was in the form of precipitate. The export of lead amounted to 140,661 tons. This result differs from that given by other technical journals, which from insufficient data stated the total production of lead as 120,000 tons.

TRAMWAY EXTENSION.—A concession for a new line of tramway has been granted to the English Company, which already owns the best lines in Madrid, and the work is to be finished without delay. The assistance rendered to the Government during the elections by the employés of the company is said to have procured the concession.

THE GENERAL PHOSPHATE COMPANY.—This company, which is a French concern, and owns extensive phosphate beds in the province of Caceres and in the neighbourhood of the capital of that name, is to be dissolved. The assets are said to be scarcely sufficient to pay the secured creditors. The largest creditors are the Portuguese Railway Company, to which a sum of £28,000 is owing for transport, and the Banque de Paris, to which a sum of £20,000 is owing. At the beginning of its history the company was very prosperous, and its dividends sometimes amounted to 20 per cent. The price of phosphates having fallen, the manufacture could not be carried on at a profit. The company then tried the manufacture of superphosphates, but the production was on too small a scale to be profitable. The company was thus obliged either to increase their superphosphate works by the issue of fresh capital to the amount of £25,000, or be dissolved. The latter course has been decided upon, and thus the shareholders will lose the whole of their capital.

ROME, 9th February, 1891.

ELECTRIC TRAMWAYS IN ITALY.—The Italian patent of Foote, of Von Buch, for series-running electric tramways has been purchased by Mr. Cattori, and the first line, by way of experiment, from Piazza del Popolo to Ponte Molle, in Rome, a distance of about two miles, has just been completed. Permission to erect the poles and overhead line was obtained in February, 1890, at which time the installation of the machinery was commenced. The plant consists of one Robey 30 nominal horse-power semi-portable type boiler; two simple high-pressure vertical steam engines of 60 indicated horse-power, with 120lb. steam pressure, supplied by J. G. Statter & Co.; and two series-wound continuous-current dynamos, 52 amperes 850 volts, from the same firm. These dynamos are fitted with a constant-current regulator. The engines and dynamos are in duplicate, one set only being worked at a time, while the other is kept in easy motion ready for emergency. The line, of No. 2 silicious bronze, consists of four wires placed at an elevation of 20ft. from the ground, running parallel with each other at about 6in. apart, and almost direct over one rail. This disposition was considered best, as the contractors were thus enabled to use shunt brackets—the tram line running all the way close to the footpath. The overhead line is divided into as many sections as there are turn-outs, and automatic switches are placed at the breaks to perform the operation of joining up the sections as required on the passage of the cars to ensure the continuity of the line and cars in series. The cars, three in number, are supplied with two motors of 15 e.h.p., each wound in series, this power being necessary to ascend a short hill of 1 in 13. The regulation of the motor is effected by the insertion of more or less resistance as a shunt across the field of the two motors. Thus, when no shunt is in circuit, the motor runs at full speed, this being equivalent to infinite resistance, and with a small resistance of about ·1 ohm the power is reduced to 3 or 4 horse-power, while with a short circuit of the field no power is received and the motors come to rest.

A ROMAN SHIP CANAL.—A commission met in the Prefecture Palace in Rome recently to consider a project which has been presented to the Italian Minister of Public Works regarding the construction of a ship canal from the coast to Rome.

NEW YORK, 31st January, 1891.

THE IRON AND STEEL TRADE.—The outlook for both iron and steel is not very encouraging. There is not a very great amount of business to be done, and as makers generally could take many more orders prices suffer in the competition. In pig iron, notwithstanding the large decrease in output which has been made, the demand is very light. Well-known brands sell with no difficulty in small lots, but concessions must be made on everything else. No. 1 foundry is selling from $17 to $18 per ton, No. 2 at from $16 to $17, and gray forge from $14·50 to $15. The outlook for manufactured iron is no better. The capacity is far in excess of present needs, and it is impossible for mills to get orders for the future. Prices suffer in consequence, but there is little inclination to curtail output, as it is hoped that business will soon improve. Little is doing in steel rails. Prices are maintained at $30 per ton. Many of the roads are holding back their orders in hopes of lower prices. Steel in other shapes has improved. While there is not a large amount being placed in orders, prices have advanced about $1 per ton. Mills have plenty of work, as most of the large consumers have placed their orders at old rates. The production of pig iron in 1890, according to the bulletin of the American Iron and Steel Association, shows an increase of over 21 per cent. over 1889. The total production was 9,202,703 tons of 2,240lb. each. The production for the second half of the year was slightly greater than that for the first, and would have been much larger but for the blowing out in December of many furnaces in the Alabama districts, caused by the strike of the coal miners, and for the financial stringency. The increase for the year was well distributed, Pennsylvania making an increase of 763,927 tons, and Illinois the next largest, of 184,204 tons. The production of Maine, Massachusetts, and Connecticut declined, and Washington made no pig iron in 1890.

TUNNEL UNDER GRAY'S PEAK.—The Atlantic-Pacific Railway Tunnel Company is driving a tunnel under Gray's Peak, sixty miles west of Denver, Col. The enterprise has been ten years in progress, and thus far the excavation, which is an 8ft. by 14ft. heading, has proceeded into the mountain on the east side a distance of 3,000ft., and on the west side a distance of 1,400ft. The total length of the tunnel will be 25,200ft. According to the *Engineering News*, the enterprise is carried on primarily to tap the mineral veins in the mountain, which are claimed by the projectors to be exceedingly rich in silver, lead, and gold. After the tunnel is completed, however, it is intended to enlarge it and open it for railway traffic, and an extension of the Utah Central Railway, to form a through line from Denver to Salt Lake City, is projected. It is claimed that this line will furnish a route from Denver to Salt Lake 200 miles shorter than any existing, and will afford a crossing of the main range of the Rocky Mountains 1,000ft. lower than the Union Pacific or the Denver and Rio Grande. Thus far, about a mile of tunnel, including side drifts, has been driven by hand power, but a plant of ten Rand drills, with Ingersoll air compressors, has just been put in, and an electric lighting plant is soon to follow.

THE DALLES BOAT RAILWAY PLAN.—This plan, for passing the obstructions in the Columbia River, has failed to pass the House Committee on Rivers and Harbours. The boat railway, with its hydraulic lifts, was estimated to cost $2,800,000, and $80,000 annually to operate it. The estimate for locks and canals was $3,754,355. The final outcome of the arguments before the Committee was the endorsement of a temporary portage railway around the obstructions, to cost $431,500.

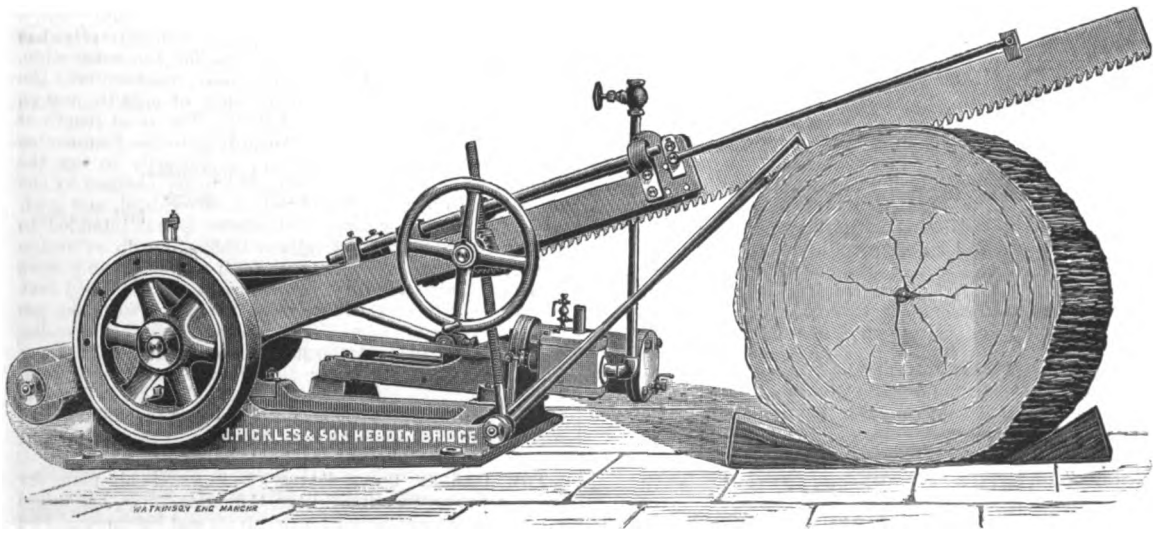
COLORADO MINES.—The value of the production of Colorado mines for 1890 is $34,871,340, divided as follows: Silver, $25,259,906; gold, $4,512,136; lead, $4,749,852; copper, $349,446. There were 19,443,268 ounces of silver put upon the market, 218,295 ounces of gold, 53,448 tons of lead, and 2,378,139 pounds of copper.

PHILADELPHIA, 30th January, 1891.

THE COAL TRADE.—The anthracite trade is dull, partly due to the season and partly to the exceedingly bad weather, which has practically isolated the larger cities from each other for the past week. There will be a meeting of the representatives of the trade to-day to arrange February shipments, but it is not likely that any attempt will be made to alter prices. The capacity of the mines is now so large that some permanent method of controlling shipments should be adopted. In the census year the mines worked only two-thirds of the year, and even then produced more than the market would take, and it is expected that the production for the present year will reach 39,000,000 tons, or an increase of about 10 per cent.

MINE DISASTER.—An explosion in the "Mammoth" shaft of the H. C. Frick Company's mines near Mount Pleasant, Pa., resulted in the death of 107 miners. The mine had always been noted for the entire absence of fire-damp, and the ordinary open lamp was used. A search party found fire-damp in the shaft, and had to be withdrawn until the mine was well ventilated. All the men at work in that particular shaft were killed. The cause of the explosion is believed to be the opening of a gas pocket, as the fireman had made his rounds shortly before the men went to work.

THE EIGHT-HOUR DAY.—Plans have been completed for the coalminers' struggle for an eight-hour day, which is to be commenced on May 1st. About 150,000 men will be directly involved. At the Convention of the American Federation of Labour it was decided to support the miners for next May. The President of the United Mines Workers, in summoning the annual Convention in Columbus next month, lays emphasis on the same subject. The present agitation in the Connellsville region and the expression from other bodies show that the men are ready. An immense strike fund is being accumulated, and the labour leaders say that on commencing the strike they will have for immediate use nearly $1,000,000, and after that time regular levies will amount to about $50,000 per week.



LOCOMOTIVE ORDERS.—The Baldwin Locomotive Works have received an order for fifty locomotives from the Government of New South Wales, another for thirty locomotives for the New York Elevated Railroad, and a third order from the Central Railroad of Brazil for thirteen locomotives.

FROM CHICAGO TO SEA BY CANAL.—About two years ago a company was formed to operate a line of steamships from some European port to Chicago, bringing out miscellaneous freight and carrying back dressed beef and dairy products. Nothing was done at that time, owing to the shallowness of the canals, but as more water is now to be had the project is being again revived. An agent of the company is now on a visit to the different lake cities soliciting freight by the new line, and is meeting with success enough to satisfy the company that plenty of freight can be obtained. It is proposed to run weekly steamers both ways, and a capital of $5,000,000 will be required to make the undertaking a success.

STEAM POWER LOG SAWING MACHINE.

CONSTRUCTED BY MESSRS. J. PICKLES & SONS, ENGINEERS, HEBDEN BRIDGE.

STEAM POWER LOG SAWING MACHINE.

THE above illustration represents an improved machine, with steam engine combined, for cross-cutting large logs, and is made by Messrs. John Pickles & Son, Royd Iron Works, Hebden Bridge, Yorkshire. The advantage claimed for machines of this class is that they are available in situations such as forests, where the introduction of shafting and pulleys would be undesirable. The construction of the machine will be readily understood from the engraving. Fixed to a strong base-plate are a small horizontal steam engine and a saw frame, the latter being supported on trunnions. The timber to be operated upon rests on the ground, and is firmly secured by means of wedges and dogs, as shown. The saw receives a reciprocating motion from the steam engine by means of a strong crank and connecting rod, and the feed of the saw is adjusted by means of a hand-wheel and screw, as shown. The weight of steam used, we are informed, is exceedingly small for the work got through, and the name of the makers, who have had considerable experience in wood-working machinery, is a general guarantee for the quality of the workmanship.

CLYDE SHIPBUILDING FOR JANUARY.

THE output of new tonnage from the shipbuilding yards on the Clyde during the past month was, as is usually the case in January, much below the average. In all there were launched seven vessels, having an aggregate tonnage of 16,670 tons. Of this number four were steamers, representing 10,500 tons, and three were sailing vessels, with a total tonnage of 6,170. Nearly one-half of the total output was made up by the new State liner, "State of California," and the iron steamship "Lightning." The former is built of steel throughout to meet the requirements of the British Admiralty for transport service, and is a unique specimen of a Clyde-built cargo and passenger vessel. She has a cargo capacity of 5,300 tons, and is intended for service between Glasgow and New York. Her principal dimensions are as follow:—Length, 400ft.; breadth, 46ft.; and depth, moulded, 32·75ft. The hull is subdivided by eight water-tight bulkheads, each carried to the upper deck. Superior accommodation is provided for 260 first-class passengers, while, in addition, 750 steerage passengers may be berthed in the 'tween decks. Triple-expansion engines will be fitted, having cylinders of 34in., 55in., and 88in. diameter respectively, with a stroke of 54in., and will be supplied with steam from three steel boilers at a working pressure of 150lb. per square inch.

The contracts placed during the month amount to upwards of 20,000 tons, and nearly the whole of these orders were secured by builders at Greenock and Port Glasgow. The construction of two large steamers, each of 7,000 tons, has been entrusted to Messrs. Caird & Co., Greenock, by the P. and O. Company, London, and in addition the Messrs. Caird have secured the contract for lengthening the s.s. "Rome" and s.s. "Carthage," two of the same company's steamers; Messrs. Scott & Co., Greenock, are to construct a steamer of 3,000 tons for Messrs. J. Swire & Sons, of London; and Messrs. Russell & Co. and Messrs. Hamilton & Co., of Port Glasgow, each received an order for a large sailing ship.

The following are the particulars of vessels launched during the month:—

SCREW STEAMERS.

"Gurly," steel, twin-screw, 900 tons, built by Messrs. Murdoch & Murray, Port Glasgow, and fitted with triple-expansion engines by Messrs. Muir & Houston, Kinning Park, for the South American fruit trade of Mr. Jacob Christensen, Bergen.

"Julia," steel, 1,800 tons, built and engined by Messrs. D. J. Dunlop & Co., Port Glasgow, for the Sobrinos de Herrara of Havana, and intended for service between Cuba and Porto Rico.

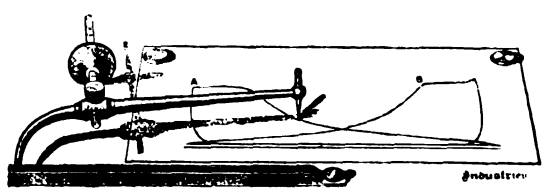
"Lightning," iron, 3,300 tons, built and fitted with triple-expansion engines by Messrs. D. & W. Henderson, Partick, to the order of Messrs. Apcar & Co., Calcutta, and intended for trade between India and China.

"State of California," steel, 4,500 tons, built and engined with triple-expansion engines by Messrs. Alexander Stephen & Sons, Linthouse, to the order of the State of California Steamship Company, Glasgow, and intended for the Atlantic trade.

SAILING VESSELS.

"Melpomene," steel, 1,780 tons, built for Hamburg owners by Messrs. Charles Connell & Co., Scotstoun.

"Robert Duncan," steel, 2,000 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, for Messrs. Leitch & Mair, Greenock.



"Thistlebank," steel, 2,390 tons, built by Messrs. Russell & Co., Port Glasgow, for Messrs. A. Weir & Co., Glasgow.

SYNOPSIS OF LAUNCHES.

	Steamers. No.	Tonnage.		Sailing Vessels. No.	Tonnage.
Great Britain	1	4,500	...	2	4,390
Germany	—	—	...	1	1,780

India	1	3,300	...	—	—
Cuba	1	1,800	...	—	—
Total	4	10,500	...	3	6,170

A NEW PLANIMETER.

WE illustrate herewith a new planimeter which will be of interest to those who have occasion to take and compute indicator cards. None of the rough-and-ready methods for computing the area of cards are particularly simple in their application or accurate in results; and, therefore, a planimeter is a highly desirable instrument, and should be purchased as a necessary part of an indicator. The present instrument differs very considerably from those in ordinary use, and is possessed of some points of great convenience. As is well known to those who have occasion to use the planimeter an occasional source of trouble is the necessity of the recording wheel travelling sidewise. Of course it should accomplish this without revolution, but it does not always do so unless the instrument is very carefully managed.

The present integrating machine is designed for the special purpose of furnishing a ready means for measuring indicator diagrams simply and rapidly. From its construction, it will be observed that the slipping motion of the wheel in running over or on to the card is in a very large measure avoided. The recording wheel is knife-edged and free to move on its spindle, and indicates by the distance it has travelled along its axis, instead of with a vernier as is usual. In operating the instrument it is only necessary to slip the wheel against the shoulder which forms the zero point on the scale, and then trace the diagram with the pressure point from the upper left corner of each card, pressing in the direction in which the hands of a clock move. The scale engraved on the spindle gives, on completing the tracing, the number of square inches in the card.

This new instrument is said to work very satisfactorily for the purpose intended, and is highly recommended by Messrs. Hines & Robertson, of New York, who supply it. Its merits are simplicity, and the ease and rapidity with which it can be manipulated, without special delicacy in adjustment. For the description and illustration of the above we are indebted to the *Electrical World*, of New York.

SPRING FRAME SAFETY BICYCLE.

ONE of the most striking features at the recent Stanley Cycle Show, as mentioned in our report, was the duplex bearing spring frame safety bicycles and tricycles constructed by Mr. W. E. Roberts, of Bristol. The principle on which these machines are built is both simple and effective, and involves a divided outer bearing bolted together and surrounding the primary bearing carrying the pedal spindle—forming what is known as the bottom bracket. Arms or projections radiate from each bearing, those from the first or primary

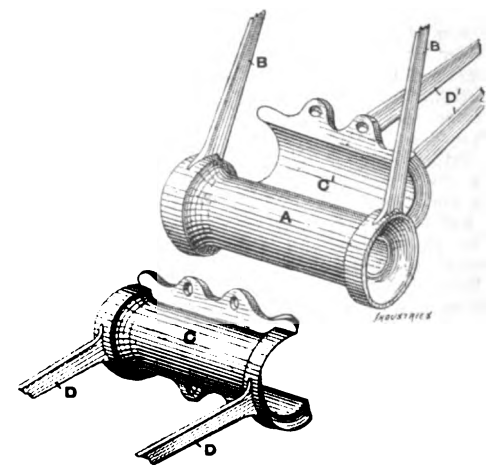

FIG. 1.

bearing being used to support or form the seat standard, which renders this bearing a fixed one, while the arms from the outer bearing, which oscillates, carry the axle of the driving wheel or wheels in one direction, and in the opposite a spring attached to the frame of the machine, so that obstructions in the path of the machine are easily surmounted by the driving wheel by reason of its oscillation upon the bottom bracket spindle. The front or steering wheel is ingeniously mounted upon one end of a short lever connected by a swivel to, and fulcrumed upon, the bottom of the steering fork; a

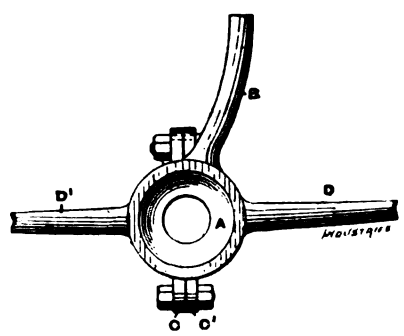

FIG. 2.

second fork fixed to this lever oscillates within the steering fork, and is connected thereto by a spring, so that the front or steering wheel rises over obstructions with the same ease as the driving wheel or wheels. Referring to the accompanying sketches (Fig. 1) A is the primary bearing with the arms B, C, and C', the

Digitized by Google

outer bearing having arms D and D¹. Fig. 2 shows the same when the outer bearing is bolted together surrounding the fixed bearing. B is the seat standard, C and C¹ the outer bearing lugs, D the arms carrying driving wheel axle, D¹ the arms connected by a spring to the frame. The springs practically bear the weight of the driver, and as no seat spring is needed the distance between the driver and the pedals remains always constant, so that "slipping" the pedals is improbable. We are informed that these machines have been ridden over brick heaps, kerb stones, and every description of uneven road without causing any great inconvenience to the rider.

SHIPBUILDING NOTES.

On the 24th ult. Messrs. Richardson, Duck, & Co. launched from their yard a steel screw steamer, the "Sledmere," of the following dimensions:—Length, between perpendiculars, 270ft.; breadth, extreme, 36ft. 6in.; depth, moulded, 19ft. 1½in.; and a gross tonnage of about 1,930 tons. This vessel, which has been built to the order of Messrs. G. R. Sanderson & Co., of Hull, is classed 100 A1 at Lloyd's, and has been built under special survey. A cellular double bottom for water ballast is fitted fore and aft, the fore and aft peaks being also utilised as ballast tanks. The vessel will be supplied with four steam winches, large donkey boiler, steam steering gear, stockless anchors, double derricks, and all modern appliances for speedy loading, discharging, and manœuvring. The engines, which are by Messrs. Blair & Co., Limited, Stockton, have cylinders 20½in., 33½in., and 55in., with 36in. stroke and 100lb. working pressure.

On the 27th ult. Messrs. Ropner & Son launched a steel screw steamer, "Alton Tower," of the following dimensions, viz.:—Length, over all, 324ft.; breadth, 40ft. 6in.; depth, moulded, 23ft. 7in. She will be classed 100 A1 at Lloyd's, and carry 4,350 tons deadweight on Lloyd's summer freeboard. She is fitted with a cellular bottom for water ballast, and is built on the web-frame principle, with all the latest improvements for a first-class cargo steamer. Her engines are by Messrs. Blair & Co., Limited, on their improved triple-expansion principle, of 1,200 i.h.p., with two large steel boilers working at 160lb. The steamer has been built to the order of Mr. Charles Furness, West Hartlepool, for Messrs. F. Stumore & Co., London.

On the 27th ult. the s.s. "Dunbeth," built by Messrs. Craig, Taylor, & Co., Stockton-on-Tees, to the order of Messrs. Macbeth & Gray, Glasgow, and under the superintendence of Mr. J. Donaldson, ran her trial trip from Leith, where the vessel was completed, and which proved very satisfactory. The dimensions of the vessel are as follow:—300ft. by 37ft. 9in. by 21ft. 9in. She is built on the web-frame and cellular bottom principle. She has steam windlass by Messrs. Emerson Walker & Thompson Bros.; outfit of winches by Messrs. Clarke, Chapman, & Co.; and steam steering gear by Messrs. Alley & Maclellan. Her engines, on the triple-expansion surface-condensing system, are by Messrs. Dunsmuir & Jackson, Govan, Glasgow, with cylinders 22in., 34in., 56in., with 39in. stroke. She steamed under the Forth Bridge, and on a run of about 20 miles a mean speed of nearly 11 knots was obtained.

On the 29th ult. the twin-screw steamer "Iris," built and engined by Messrs. Blackwood & Gordon, was officially tried. The vessel has been built to the order of Messrs. Hill, Gomes, & Co., Manchester, and has been constructed to the highest class at Lloyd's. The speed was tested on a double run between the Cloch and the Cumbrae light. A mean speed of 13 knots was attained against the tide, a speed about a knot in excess of the guarantee. The engines are of triple-expansion type, and are fitted with Morton's patent valve gear.

On the 29th ult. the fine new steamer "Heighington," built by Messrs. William Gray & Co., Limited, to the order of the Hudson Shipping Company, West Hartlepool, went on her trial trip in Hartlepool Bay. The vessel is 324ft. long over all, 40ft. 6in. beam, and 23ft. 8½in. in depth, moulded, having a deadweight capacity of 4,350 tons, and is classed 100 A1 at Lloyd's. The engines are supplied by the Central Marine Engine Works of Messrs. W. Gray & Co., and are of the triple-expansion type, of 1,200 i.h.p., having two large steel boilers working at a pressure of 160lb. A speed of a little over 11 knots per hour was obtained.

On the 5th inst. the steamer "Patagonia," belonging to the fleet of the Pacific Steam Navigation Company, of Liverpool, which has just been refitted by the Naval Construction and Armaments Company, Limited, at Barrow, with a new set of triple-expansion engines, went out for her trial trip of 130 miles, when the new machinery worked with the utmost satisfaction.

On the 9th inst. there was launched from the yard of Messrs. W. Doxford & Sons, Limited, the largest sailing vessel yet built on the north-east coast. The registered dimensions are:—Length, 312ft.; breadth, 46ft.; depth, 25ft.; and gross register, 3,070 tons. The vessel is built of steel to Lloyd's 100A1. rules, with poop bridge and topgallant forecastle, has two steam winches, by Welford Bros.; donkey boiler of 80lb. working pressure, by Messrs. Riley Bros., of Stockton; and windlass by Messrs. Clarke, Chapman, & Co., with their latest improvements. The vessel has four masts, and is built to the order of Messrs. J. Joyce & Co., of Liverpool,

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, February 13th at 7.30 p.m. Students' meeting. Paper to be read: "The Cleaning and Deepening of Rivers and Canals by Means of the Transporting Power of Water," by Mr. W. H. Wheeler.

Physical Society.—Friday, February 13th. Discussion on Professor Minchin's paper on "Photo-Electricity." Paper to be read: "The Change in the Absorption Spectrum of Cobalt Glass Produced by Heat," by Sir John Conroy, Bart.

Balloon Society of Great Britain.—Friday, February 13th, at 8 p.m. Paper to be read: "Railway Servants' Hours of Duty," by Mr. Charles Jardine.

Royal Institution.—Saturday, February 14th, at 3 p.m. Lecture on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

NEXT WEEK.

Society of Chemical Industry.—Monday, February 16th, at 8 p.m. Papers to be read: "Incandescent Gas Lighting," by Mr. W. Mackean; "The Volumetric Estimation of Alumina," by Messrs. Cross and Bevan.

Society of Arts.—Monday, February 16th, at 8 p.m. Cantor Lecture I., on "The Electric Transmission of Power," by Mr. Gisbert Kapp. Wednesday, February 18th, at 8 p.m.: "Methods and Processes of the Ordnance Survey," by Colonel Sir Charles Wilson, K.C.B., F.R.S.

Royal Institute of British Architects.—Monday, February 16th, at 8 p.m. Sessional meeting.

Institution of Civil Engineers.—Tuesday, February 17th, at 8 p.m. Adjourned discussion on the paper by Messrs. Atkinson on "On Electric Mining Machinery."

Sanitary Institute.—Tuesday, February 17th, at 8 p.m. Paper to be read: "Sanitary Appliances," by Professor W. H. Corfield.

Royal Statistical Society.—Tuesday, February 17th, at 7.45 p.m. Paper to be read: "The Vital Statistics of Peabody Buildings and other Artisans' and Labourers' Block Dwellings," by Dr. A. Newsholme.

Owens College Union Engineering Society.—Tuesday, February 17th, at 7 p.m. Paper to be read: "Lessons from Boiler Explosions," by Mr. W. H. Oldham.

Royal Meteorological Society.—Wednesday, February 18th, at 7 p.m. Ordinary meeting.

Chemical Society.—Thursday, February 19th, at 8 p.m. Ordinary meeting.

PRICES CURRENT, 11th February, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.		Best. £ s. d.

" English Ingots	94	15	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues quiet, with small trade. Published statistics on January 31st show a decrease of about 4,700 tons in stock during the month. Chili bars are stronger during the last few days, values having advanced to £52 15s. to £53 2s. 6d. cash, with moderate business reported. Manufactured steady at £65 to £66, "strong," according to specification.

Tin has improved steadily during the week, to-day's quotations for foreign being 27s. 6d. higher than in our last report.

Lead: Inactive, with small business, values practically unchanged.

Spelter is advancing, owing to small stocks everywhere and an improving demand. Prices are higher on the Continent than in England.

HOME INDUSTRIES.

LONDON, 12th February, 1891.

The Money Market.—A firmer feeling has pervaded the money market this week, the prevalence of a demand for gold for Germany helping to keep rates steady. The return of the gold borrowed from the Bank of France in November has not had much effect, as it had been taken fully into account before. But while rates have been steady there has been no great advance, and 1½ per cent. represents the limit quotation for call loans and 2 per cent. for the discount of three months' Bank bills. On the Stock Exchange business has been on a small scale, and the account dealt with at this week's settlement was very limited. A steadier tone is now to be noted in prices in nearly every department. Home railways have become distinctly firmer since the last of the dividends were announced, and there has been no disposition to sell. The ascendency of the "bull" interest in Wall Street has had a favourable influence on American railroad stocks here, and Canadian railways have been sympathetically firm. Foreign bonds keep well up, and Argentines have somewhat improved. Silver securities, after a considerable dip, have recovered, but the prospect for them is still very uncertain. There is a fair degree of activity in mining shares, without any pronounced feature. Industrial and miscellaneous shares are equally devoid of particular interest.

Great Northern Telegraph Company.—The traffic returns of this company show that the receipts in January, 1891, were £20,800, the receipts for the corresponding month of 1890 and 1889 being £19,600 and £22,400.

Royal Botanic Society.—A meeting of this Society was held on the 7th inst., at which the secretary, in announcing the gift to the Society of some seeds of the Parà rubber tree, stated that the growth of indiarubber and gutta percha was at the present time a matter of great importance. Gutta percha was imported into Europe in 1842, and was shortly afterwards used for the insulation of the first submarine telegraph cable. Up to the present moment no substitute has been found to take its place. In some interesting papers lately published in the *Electrical Review* it had been stated that from the "wholesale cutting down of adult trees," and the "reckless clearing and burning of the forests," the trees furnishing the most valuable kinds of gutta percha had become exceedingly scarce and in most localities utterly extirpated. This was also rapidly becoming the case with the trees which supply the many varieties of indiarubber, and, sooner or later, all natural vegetable products used by man must be artificially cultivated, as the natural supply never kept pace with the artificial demand. Some few attempts have been made to cultivate indiarubber, but as yet not very successfully.

The Junior Enginkeering Society.—The visit of this Society to the Trinity House workshops and steam vessel "Irene," took place on the 31st ult., permission having been obtained through the kindness of Sir James Douglas, F.R.S., Vice-President. Under the guidance of the officials, the members were shown through each department of the establishment. The work carried on includes repairs to machinery of the Corporation's steam vessels, of which there are ten; the illuminating and fog signal machinery and apparatus of lighthouses, light vessels, and lighted beacons and buoys; repairs to day beacons and buoys and conversion of worn chain cables from light vessel to buoy service. There is a gasworks for making oil gas and compressing it for buoy illumination. On proceeding to the docks the party were then shown over the "Irene," a vessel which was built last year by Messrs. Palmer's Shipbuilding and Engineering Company.

Association of Sanitary Inspectors.—On the 7th inst. there was held the eighth annual dinner of the Association of Public Sanitary Inspectors of Great Britain, Dr. B. W. Richardson, F.R.S. (President), occupying the chair. The President, in proposing the toast of "Success to the Association," spoke in high terms of the work which was being performed by the members of the Association throughout Great Britain. It resulted in the reduction of death, of disease, and of sorrow, and there could be no finer work than that for any man to perform. According to figures given by Mr. Wilson Noble, 125,000 deaths occurred every year in Great Britain which were preventable. There were thirty-nine cases of sickness for every death; each case of sickness lasted on an average 18½ days, which meant a total loss of 78¼ million days of labour for the year. That loss, computed at 2s. a day, meant that the sum of 7¾ millions sterling was lost every year. This computation did not include the extra cases of sickness which occurred among the working classes from exhaustion. If they took half the cases he had named they found that each year the work of 1,000 men for 100 years was lost by sickness.

Machinery Exhibition.—There is to be held at the Agricultural Hall, Islington, from 23rd April to 2nd May, the third annual international exhibition of machinery, manufactures, appliances, and inventions of interest to engineers, electricians, builders, and ironmongers. The manager is Mr. Harry Etherington, 43, New Oxford Street, W.C.

The Edison and Swan United Electric Light Company, Limited.—The directors of this company have decided to pay an interim dividend for the half-year ending 31st December, 1890, at the rate of 7 per cent. per annum upon the A shares, to be distributed in accordance with the articles of association.

MANCHESTER, 12th February, 1891.

Sewage Experiments.—The report of the committee appointed by the Salford Corporation to undertake experiments at the sewage works of that borough has been published. Four systems of purification were tried—the International, Electrical, Aluminoferric, and Barry. The first-named company, by their treatment, reduced the sludge very considerably as compared with the lime process, and the effluent produced was very clear, no decomposition arising after its discharge. The electrical treatment also gave very good results, and the sludge produced was less than that by any other system, the effluent also being very good. The other two systems were not so successful, but of the two the aluminoferric was the better. In this case there appeared to be some danger of decomposition of the effluent at a later stage. The committee recommend the adoption of either of the first two systems under certain guarantees.

New Factory Bill.—A Bill has been drafted by the cotton operatives, in which certain amendments to the Factory Acts are proposed. The principal features which are likely to be opposed are two clauses relating to the admission of air and to an allowance of time for cleaning. The first provides that not less than 600ft. of fresh air per hour shall be admitted into each room for every person employed. The second proposes a stoppage of the machinery half an hour earlier on Saturday to avoid accidents and give the workpeople time for cleaning. The proposals will probably meet with strenuous opposition.

The Ship Canal.—The proposal made by the directors of the above company that the Corporation of Manchester should join them in an application to Parliament for leave to assist the company financially has been favourably received. A special committee has been formed to investigate the matter, and Mr. Hill, the engineer of the city waterworks, has been asked to check the estimates of cost submitted. The proposal has met with much public favour, and the neighbouring borough of Salford is likely to assist the enterprise, one or two strong expressions in favour of the scheme having come from that district. It is suggested that a representative of the Council should join the board of directors, thus giving a semi-official character to the connection.

The Calico Printers' Union.—The negotiations with this object are beginning to take shape. Several firms of high repute have consented to join the Union, and although others decline to amalgamate, the market will be much strengthened by the adhesion of the remaining houses.

Civil Engineering Students' Dinner.—The Association of Manchester Students of the Institution of Civil Engineers held their fourth annual dinner on the 11th inst. Mr. J. Abernethy, past-president of the Institution, occupied the chair, and among the large number present were Professor Boyd Dawkins, Mr. R. H. Heenan, and Mr. E. Leader Williams.

The Linen and Jute Trades.—In order to carry out business, sellers have been obliged to reduce prices. Orders are often lost even by those willing to make slight sacrifices. Buyers are very careful in keeping down stocks to the lowest workable level, while producers, owing to the action of the Bleachers' Union in advancing prices for bleaching, find it more difficult than before to undertake orders. Unfavourable rumours regarding a well-known firm of merchants have been shown to be exaggerated, and there is a more cheerful feeling in the quarters that would have been affected. There is no truth in the report made by a shareholder that Messrs. J. S. Westhead & Co., Limited, will be wound up. The demand for coarse goods is fair. That for fine and fancy makes drags, the season having, so far, been unfavourable. In shipment there is no improvement.

GLASGOW, 12th February, 1891.

Minerals.—Business has now resumed its ordinary course after the paralysis of the six weeks during which the strike lasted. The pig iron furnaces are being relighted, and on the whole there is a more hopeful feeling in commercial and industrial circles than there was before the close of the year. The price of pig iron is still low, and there is but slender encouragement for the makers to resume production; but the stocks of special brands are practically exhausted, and the advisability of keeping their hold upon their customers and the prospect of an increased demand in the spring have made the relighting of the furnaces desirable. At the close of the year there were in Scotland only 6 furnaces in blast out of 140. On 1st January last year there were 88 furnaces in blast. There are at present 560,000 tons in store, a decrease since the beginning of the year of nearly 30,000 tons.

Speculation in Pig Iron.—The speech of Sir Richard Webster has caused some excitement in the iron trade, although his remarks were based on an evident misapprehension. It is quite clear that when he spoke of there being in circulation warrants for which there existed no corresponding quantities of iron, he meant contracts, and not warrants. Messrs. Connal very properly brought this unwitting mistake under the notice of the Attorney-General. It is thought probable that the Attorney-General will attempt some legislation on the subject of pig iron speculation.

The Recent Strike.—The blast furnacemen who have been on strike for seventeen weeks, during which the furnaces have remained closed, have been supported by subscriptions from the Cleveland districts. It has been alleged that the subscriptions from the English trade unions have been supplemented by persons who were interested in the Cleveland iron trade, and who hoped that the strike would benefit the Middlesbrough district at the expense of the West of Scotland. This explanation of the strike is, however, rather doubtful. The effect of such a movement, even if it were successful, could not be otherwise than temporary. As a matter of fact, the cessation of production has contributed to prevent the price of pig iron from falling, perhaps, to an unprecedented level. Meanwhile there has been plenty of iron for use, and, besides, it is only for certain purposes that Middlesbrough and Scotch iron compete against each other. Although, no doubt, such expedients have been tried, it seems absurd to charge the Cleveland ironmasters with deliberately inciting the Scotch blast furnacemen to revolt for the purpose of raising the price of production of iron in Scotland. It is to be noted, however, that the importation of Cleveland pig iron into Scotland has increased considerably. The importation for 1891 is already over 28,000 tons, as compared with only 16,000 tons in 1890. The effect of the cessation of production has been to run off about 100,000 tons of stock, and to this extent to strengthen the market. The Messrs. Dixon, who are preparing to relight their furnaces, have apparently resolved to employ only non-union men. They are adopting precautions against their employés being interfered with, and are, it is said, paying their men 30s. per week, with board.

Scottish Railways.—The arrangements as to the discussion of grievances by the North British Railway Company and their men have again been interfered with by the question of the "graded system." It is, however, almost certain that terms of agreement will be speedily arrived at.—The Amalgamation Bill of the North British and Glasgow and South-Western Railways has been withdrawn, the opposition of Sir John Burns, Bart., and of those who entrusted him with their proxies, having removed any chance of success.

Shipbuilding.—It is reported that Messrs. W. Denny & Bros., Dumbarton, have received an order for a vessel of 7,000 tons, similar in all respects to the "Scot" just built by them for the Union Company's South African Line. The "Scot" is expected to be completed in about two months.

(From our own Correspondents.)

LIVERPOOL, 11th February, 1891.

The Liverpool Overhead Railway.—The progress of the construction of this railway during the last twelve months has been disappointing, but the erection of the columns and girders is now proceeding rapidly. At the half-yearly meeting, held yesterday, Sir W. B. Forwood spoke very hopefully of the enterprise, and said that when the line was completed it would be the most valuable railway property in Lancashire. It is expected that the length from the northern terminus to St. Nicholas's Church, which contains some of the heaviest work, will be completed by next September or October. Tenders for the electric motors and cars have been invited, but no system has yet been definitely decided upon.

Liverpool Engineering Society.—At a meeting of the Society, held on the 4th inst., the President, Mr. Ferdinand Hudleston, being in the chair, a paper was read by Mr. Joseph Boult, entitled "Notes on the Phenomena of Tidal Rivers, with Special Reference to the River Mersey." The author dealt with the differences between tidal and non-tidal rivers, with the amount of tidal sea water entering the Thames and the Mersey respectively, and with the difference in tidal range between the West Coast of Britain and the East Coast of Ireland, and the cause of this difference. The various phases of the tides in the tidal channels at the mouth of the Mersey were next discussed, together with the numerous movements of the channels of the upper estuary.

LEEDS, 11th February, 1891.

The Iron and Steel Trades.—The iron and steel trades of this district have during the past fortnight been very quiet, and there is still little sign of a revival of activity. The tendency of buyers is to order only for immediate wants, in the hope of a favourable change taking place. Prices of manufactured iron and steel remain nearly stationary. The cause of the quietness in the market is ascribed to the present high rate of fuel, and there is no doubt that the manufacturers of steel and iron who have to purchase coal are placed at a disadvantage in giving quotations, as compared with firms who are able to obtain coal from their own pits.

The Coal Trade.—Business in the coal trade of West Yorkshire continues buoyant, and the whole of the pits are running full time. There seems no prospect at present for a reduction of prices. The tonnage of coal sent to Hull last month was slightly less than in the corresponding month of 1890, but this may possibly be owing to the fact that the waterways were frozen for a lengthened time.

The Engineering Trade.—One or two of the large firms have lessened the amount of overtime or put a stop to it altogether. The engineers are, perhaps, in a better position than the tool makers with regard to the future. The nail trade is dull, and agricultural implement makers are only fairly busy. A continuance of the present weather should, however, bring about a change in their favour.

Digitized by Google

SHEFFIELD, 11th February, 1891.

Iron and Steel.—The iron and steel trades continue active throughout this district. The important part of the steel trade here consists of heavy work, such as shafts for marine work, heavy guns, and armour plates.

Trial of Armour Plates.—Messrs. Cammell have been very successful in a recent trial of one of their "Wilson" compound plates at Portsmouth on board the "Nettle." This plate was 8in. in thickness, and measured 8ft. by 6ft., and three Palliser chilled projectiles were fired at it from the new 6in. breechloading gun with 32lb. of E X E powder, developing a striking velocity of 1,566ft. per second. The shots were grouped in the centre of the plate at the points of an equilateral triangle. In no case did the indentation exceed 2in., and, with the exception of a few hair cracks through the hard steel face, the plate was comparatively sound. This plate was one forming part of the belt of the Chilian cruiser "Captain Pratt," and the effect of this trial will restore confidence in compound plates.

Railway Material.—In railway work there is a falling off in the home market, and prices have declined in consequence. It is expected that New South Wales will give out some large orders for rolling stock, and that a large part of the raw material will come from this district.

General Engineering.—The Yorkshire Engine Company is engaged in the construction of Fairlie engines for the nitrate fields, electric tramways for the Isle of Wight, and also some work for the Chignecto Ship Railway. Messrs. Henry Bessemer & Co., Ld., have made a profit of £38,000 during the year, and will pay a dividend of 25 per cent. The company have lately spent a large sum on new machinery and plant.

NORTH STAFFORDSHIRE, 11th February, 1891.

The Iron Trade.—Prices continue to decline, and the position of ironmasters is assuming a critical phase. Pig iron cannot be made at the present market rates, which have fallen to 42s. 6d. per ton at works for forge qualities; and there is no margin for profit in the price of bars at £5 15s. to £6 per ton at works. The cost of production of the raw material will have to be reduced or works will be closed.

The Coal Trade.—There is still a steady demand for house coal, but manufacturing qualities are being stocked, and there are signs that prices will shortly be weakened by competition amongst sellers.

BIRMINGHAM, 11th February, 1891.

The Iron Trade.—Dulness prevails in the iron trade generally, and the closing of several sheet and hoop works in the Bilston district has a disquieting effect. Messrs. Groncutt & Sons have just closed their Bankfield rolling mills, and the Bilston Iron Company have done the same, while Messrs. Hatton, Sons, & Co., of the Bradley Sheet Works, have partly stopped operations until their financial affairs are settled. About two years ago many sheet mills were restarted in the Staffordshire district, but a reaction seems to have set in. There is much underselling of sheets, and the employers are endeavouring to reconstitute the Association in order to regulate prices. Fuel continues very high in price, and wages are high, but pig iron has a downward tendency.

Steel Manufacture.—There seems to be ample demand for the steel made in this district. All the furnaces and converters are fully employed, and other furnaces have been added at Congreave's. The projected additions of steel furnaces and plant at Round Oak Works will be a great addition to the district.

Manufacture of Anvils.—The "best" anvils are now made at many works by stamping the top half and bottom half of the body separately in dies, and then welding them together, the steel face being afterwards welded on. A recent patented improvement on this practice is to make a body in one piece, cast to shape and of mild steel, in all parts but the bick. The bick is then forged to a point to consolidate it more, and the hard steel face is either cast or welded on.

Bolts and Nuts.—The Admiralty have placed a running contract for steel bolts and nuts with the Phœnix Nut and Bolt Company, Handsworth.

Boiler Making.—All the boiler makers of the district are very busy, chiefly, of course, on steel boilers, though there are still some made of the best qualities and brands of South Staffordshire iron.

LEICESTER, 11th February, 1891.

Wool Spinning and Yarn Trades.—The local wool market still maintains a very firm tone owing to the tendency to a hardening in prices at the London wool sales. English wools are very firmly held at the recent quotations, and in some instances a very small increase in price is demanded. Though it is thought quotations have reached their lowest limit there is an absence of speculative operations, and users are content to buy only for their immediate requirements. Skin wools are freely in demand, and there is a better inquiry for short wools and demi-lustres and lustres. Spinners are a little better off for business, but they are not as yet actively employed. The yarn market is brisker, and some large contracts are offered, but spinners are demanding a better price than has prevailed for some time past.

Hosiery Trade.—Business is healthy in this industry, but some of the branches have experienced a falling off in orders. In cashmeres there are large stocks, and, as the demand has not yet developed, the production is limited. The fancy department is showing signs of increased activity. On the whole the prospects for the spring trade are good.

SWANSEA, 11th February, 1891.

Tinplates.—There is a fairly active demand for ordinary sorts and sizes of tinplates, which have reached the satisfactory price of 18s. per box for Bessemer quality. Now that the strikes at the works seem to be over, labour difficulties at the docks put obstacles in the way of rapid shipment, so that last week only one steamer cleared with tinplates for the United States, as against an average weekly clearance of three. Prices in the New York market have again advanced on the improvement of 5c. per box made known last week, and buyers are eagerly taking all that is offered at our prices. Stocks in dock warehouses and vans amounted, on the 7th inst., to 258,326 boxes, as compared with 251,891 on the 31st ult., and 234,791 boxes on the corresponding date of last year. On the 7th inst. the Llwydarth Tinplate Works were re-started under a new proprietary at Maesteg. They will give employment to fully 150 men. The death is announced of Mr. Wm. Conway, of the Ponthir Works, at the age of seventy.

CARDIFF, 11th February, 1891.

Iron and Steel.—The pig iron trade continues dull. Many things seem adverse to the producer, but there is this week an opportunity of getting coal a little cheaper, and foreign ore is less expensive on account of low freights. It is evident that the production exceeds the demand, even with such a large number of furnaces out of blast. Steel tinplate bars (Bessemer) are quoted at £5 10s.

Coal and Coke.—The steam coal trade is naturally affected by the strike of dockers, which seems to be far from a settlement. Colliery proprietors are willing to accept reduced prices for immediate shipment and for inland consumption where their loaded waggons can be released at once. With this exception, prices have undergone no change, ruling prices for 1st quality being 15s. to 15s. 6d.; 2nd, 14s. 3d. to 14s. 9d.; 3rd, 13s. 6d. to 14s.; and 4th, 12s. 9d. to 13s. 3d. The demand for small steam coal has fallen off, current figures being at 5s. 6d. to 5s. 9d. Households are in fair demand, 15s. to 16s. being obtainable for No. 3 Rhondda. Small smiths' (best) realised 10s. 6d. to 11s., and No. 2, 7s. 6d. The coke trade is in a fairly satisfactory condition, prices having now reached a remunerative level. Furnace qualities realise 20s. to 21s.; foundry, 22s. 6d. to 24s.; best foundry, 25s. 6d. to 27s. Patent fuel is quoted at 13s. 9d. to 14s. 3d.

BARROW-IN-FURNESS, 11th February, 1891.

Hematite.—A quieter business has been done this week in hematite qualities of pig iron, and very little in forge and foundry qualities. The consumption of Bessemer pig iron has somewhat fallen off, but is expected to improve again shortly, as the Moss Bay Steel Works are soon to resume operations. Prices are easier at 51s. 5d. net cash for hematite warrants—a price at which makers are undersold, as they allege that they are unable to make pig iron at less than 53s. 6d. for mixed Bessemer numbers net f.o.b. with raw material at its present price. Stocks have again increased during the week to the extent of 276 tons, although another furnace has been blown out at Workington, leaving 43 out of 76 in blast. Another furnace is to be blown out next week at Maryport. Stocks of hematite warrants in hand now represent 213,397 tons.

Steel.—The steel trade is very quiet. Heavy rail sections are at £4 15s., light sections at £6, and colliery rails at £7 per ton. Steel shipbuilding material is quiet on general account, and there is little new business on local account, but makers hold a large number of orders. Both plates and angles are quoted at £6 2s. 6d. to £6 5s. per ton. Tinplate bars move slowly at £5. Billets are in fair demand at £4 15s. Blooms and slabs are quiet at £4 10s. to £4 15s. respectively. There is a good trade in hoops at £6 10s. The wire trade is quiet. Forgings and castings are in demand.

Activity in the Building Trade.—There is a very great demand for house property in Barrow. The great development of trade and the creation of new industries have shown the urgent want of dwellings suitable for artisans. If present prospects are realised, there will be required during the ensuing two years from 500 to 1,000 new houses.

MIDDLESBROUGH, 11th February, 1891.

Pig Iron.—There was a fair attendance on 'Change yesterday, and a cheerful tone prevailed, though there was a total absence of business, and few orders had been received. Sellers are holding back in the expectation that they will get better prices when the shipping season opens. Makers are not quoting for forward delivery, but merchants are quoting 42s. per ton for prompt f.o.b. deliveries of No. 3 G.M.B., and 42s. 3d. for deliveries up to the end of March. Buyers, however, would only pay 41s. 9d. for prompt, and would not quote for forward deliveries at all Middlesbrough warrants are 41s. 9d. cash sellers. Grey forge is in request for shipment to Scotland, and is 40s. 6d. per ton. Connal's stock is 124,143 tons, an increase of 899 tons from the previous week. Local hematite is 53s. 6d. per ton for mixed numbers.

Manufactured Iron and Steel.—There is no change to be reported in finished iron and steel, and trade in steel plates is so bad that some of the mills are likely to cease working until better times. Prices are: Steel ship plates, £6 2s. 6d.; iron plates, £5 15s.; steel angles, £6 5s.; iron angles, £5 12s. 6d.; steel rails, £4 17s. 6d., all less 2½ per cent. and f.o.b. Iron chairs are £3 5s.

NEWCASTLE, 11th February, 1891.

The Coal Trade.—Since the commencement of the strike at Cardiff there has been some improvement in the steam coal trade, owing to the diversion of a few orders to this district. On the 7th inst. a meeting of coalowners' and miners' representatives was held in Newcastle, when a discussion as to the further limitation of the working hours for boys took place. No settlement was arrived at on this question, and it is understood that it will be reconsidered at a future meeting. It was arranged, however, that a reduction in wages of 1¼ per cent., due to the employers under the last ascertainment of prices, should come into operation at once. The shipments of coal and coke at Tyne Dock during the week ending on the 7th inst. amounted to 105,857 tons, being a decrease as compared with the shipments for the corresponding week last year of 5,196 tons.

Engineering.—It is understood that Messrs. Hawthorn, Leslie, & Co., who already have a large amount of Government work in hand, have received from the Admiralty a further order for engines and boilers for two cruisers now being built in the Government dockyards. The Forth Banks Works of this firm are, like their St. Peter's establishment, extremely busy. A new siding to connect the works directly with the North-Eastern Railway system is now being carried out, and when completed will be of great utility in facilitating the delivery and despatch of goods.

Tyne Dock.—The contract for deepening the entrance to Tyne Dock, so as to admit vessels of the largest tonnage, has been given out, and the work will be proceeded with immediately. The construction of the new coal loading staiths is well advanced.

The Elswick Works.—The great ordnance factory of Sir W. G. Armstrong, Mitchell, & Co. is, for the moment, somewhat slack. Many orders were finished at the close of last year, and no large order has been received in their place. In some of the shops the pressure of work is therefore much lessened, and hands are being paid off. It is believed, however, that some new orders are in course of negotiation.

Geology of British Coalfields.—Mr. W. J. Potts, of the Atlas Works, North Shields, offers ten guineas for an approved original article on the geology of the coalfield or coalfields in any single county or group of adjacent counties of Great Britain and Ireland. Communications can be sent in up to the 1st April.

Electric Lighting.—Messrs. Clark, Chapman, & Co. have just fitted a complete electric lighting installation in the large steamship "Hawkes Bay," built for the colonial meat trade by Messrs. W. Doxford & Sons, Sunderland. The firm have several other important installations now in hand.

DUNDEE, 11th February, 1891.

Jute and Flax Trades.—There is little change to be reported in either branch of the local trade. A fall in the Exchange has caused a slight decline in the price of jute, and while there is comparatively little doing prices are in favour of buyers. In Calcutta there is no change in the rupee price, sellers being firm, and "M" in a double triangle being quoted at 21 rupees per bale of 400lb. Jute yarns are fairly steady in value, and there is an average amount of business. The demand for jute goods is quiet, and makers are disposed to meet sellers. In the New York market prices are unaltered, burlaps 40in. 10½oz. being quoted at 4 1/16c. per yard and light weights at 4⅜c. The flax market is quiet, with prices in favour of buyers. Spinners are complaining that the market for yarns is unsatisfactory and the tendency of prices disappointing. Orders for linens show some improvement, but stocks of canvas are said to be increasing.

Launch of a Steamer.—Last week Messrs. Gourlay Bros. & Sons, Dundee, launched for the General Steam Navigation Company, London, a steel screw steamer, 220ft. long, 30ft. 6in. in breadth, 15½ft. in depth, and capable of carrying about 900 tons gross. She has cellular double bottom for water ballast. The machinery is to be put on board the steamer at London.

Improvement of the City.—A proposal has been submitted to the local police commission for the clearing away of a number of old buildings in the centre of the city, in order to make room for a People's Palace or Winter Garden. In the area proposed to be included the average death-rate for a period of eight years has been 39 per thousand, and one year the rate was as high as 74 per thousand. For the whole town during the eight years the rate was 20 per thousand.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 13TH FEBRUARY, 1891.

THE TENDENCIES AND PROSPECTS OF LABOUR.

ONE of the most perplexing questions that manufacturers are called on to face in the present day is that of how far they can further cheapen the cost of production, and still leave a fair margin of profit. The great demand of the world nowadays is for cheap commodities, and the nation that can furnish these in the greatest abundance, all other things being equal, will assuredly win in the race. But, to produce cheaply, there must be a combination of favourable circumstances, of which the command of moderately cheap and highly efficient labour is not the least important. This advantage has been peculiarly the privilege of Great Britain for a long series of years; but it is often questioned whether we enjoy the same superiority of labour, as compared with other countries, that we formerly did—whether, in point of fact, the labour of other countries is not excelling that of England in the matter of efficiency when compared with price. The question is often asked—Is the average result brought out by a given amount of labour, as measured by time, as good now as it was formerly? There is no reason to doubt that the average efficiency of labour, as measured in terms of the net yield of a given period of labour, is decidedly higher to-day that it ever has been. This is a matter that may be submitted to a very simple and convenient test, for the materials are at hand whereby it may be settled with almost mathematical precision in at least two of our most important industries—viz., mining and textiles.

Take, first of all, the case of the mining of iron ore in the district of Cleveland. This is one of the best tests that could be applied, inasmuch as the conditions of work have not varied much as between one period and another. The hours of labour are much the same, as are also the system of working and the character of the deposits, which are regularly defined horizontal strata, of fairly uniform composition and depth, and not, as in the case of the ores of the West Coast, liable to vary in their mode of occurrence. If there is any material difference to be taken into account, it is the difference due to the men having to journey for longer distances in proceeding from and returning to the bottom of the shaft, so that it is a difference that would presumably tell against the likelihood of a larger individual output. Bearing these facts in mind, it is a little startling to find that the average output per employé in the mines of Cleveland has advanced from 551 tons in 1874 to 784 tons in 1878, 808 tons in 1880, 889 tons in 1886, and 890 tons in 1889. In other words, as between the first and the last of these dates there has been an increase of about 80 per cent. in the productiveness of the men employed, for the same number of hours worked. The question naturally occurs—To what is this great difference due? In the case of mining, it is no doubt partly due to the increased area opened out in the mine, to the greater facility for handling the materials provided in the mine, and to the introduction of machines and other new features tending to improved methods of working. But it is chiefly due to the greater experience and efficiency of the workers, who have become more expert in their business, and have been constrained, by depression of trade, to do much work for comparatively little pay.

The advance made in the productiveness of coal miners has not been quite so conspicuous as that found in reference to iron ore mining in the Cleveland district. In the great northern coalfield, which is contiguous to the iron ore mines of Cleveland, with which there is a certain amount of interchange of labour, the men are more experienced, plodding, and steady than almost in any other. In this locality, however, there have been very striking differences in the individual industry of the men employed. In the four years ending with 1867, when the total output of the great northern coalfield was between 24 and 26 million tons a year, the average annual output per man was about 417 tons; in the next four years the average fell to about 385 tons; and in the four years following the introduction of the Coal Mines Regulation Act of 1872 the average had fallen to about 310 tons. It must, however, be remembered to the credit of the miners, that they had become demoralised during the last-named period by the inflated prices and wages that became the order of the day in 1872, and continued more or less until 1875. After the latter year the men began to do better work, and by 1880 the output had risen to 360 tons per head per annum. Since 1880 the annual average has varied between 330 and 370 tons, but it has never reached so high as it did in the period previous to the adoption of the Mines Act of 1872. No doubt this fact is at least partly due to the restrictions which that measure brought into force, and this cause should never be lost sight of in dealing with a question of this kind. Parliamentary interference with industrial operations may be necessary, and even beneficial, in the interests of the public, but it is calculated to introduce disturbances and dislocations that are often overlooked in comparing one period with another. There is another disturbing element in the case of the great northern coalfield that does not equally affect some others, and that is the fact that many of the collieries in that district, and in Northumberland especially, having exhausted the best seams of coal, are now working the minor and thinner seams, which, of course, are more difficult to mine. The difference due to this circumstance may be traced in the figures that illustrate the progress of the much less explored Yorkshire coalfield over the same period. In 1864 the average output per miner in the latter field was 270. It fell below that average for several succeeding years; but about 1869 it began to rise again, in 1880 it was 280 tons, and in 1887 it had advanced to 306 tons. For the whole period between 1880 and 1887 it was creeping upwards, and, if it has fallen away a little since then, that is only a result that almost invariably accompanies a revival of trade and a higher range of wages. Scotland, the next range of coalfields to the great northern on the one side, as Yorkshire is on the other, exhibits a more pronounced advance of efficiency than either of the other two. The highest individual annual output in any year between 1860 and 1872 was 329 tons, and this figure was reached in 1871. In the following year the output fell to 303 tons, due no doubt to the Mines Act, and in the year 1873 to 288 tons, due again to the Mines Act and the coal famine, which gave very

Digitized by Google

high wages to the miners, but from 1882 the Scotch miners began to exert themselves, and in 1880 they produced an average of 344 tons per man, which was increased to 347 tons seven years later. It has been the same throughout the country generally. The average productiveness of the miners of nearly all districts in this country has been increased within the last few years, so that the wages cost of a ton of minerals has, on an average, been less than formerly. It is, however, to be observed that this increased efficiency is most prominently displayed when business is dull and wages are low.

The textile trades are capable of furnishing another valuable indication of the extent to which the efficiency of labour is being increased or diminished in our own and other countries. Whether we measure these industries by the test of the number of spindles and looms provided per operative employed, by the number of pounds of cotton, wool, or other textile materials worked per spindle and per operative, by the total quantity and value of our textile exports per operative, or by any other reliable standard, the result is that we find an increase of efficiency in the individual product. This is, of course, not always due to the merits of the workers, but it is often, and it may be generally, owing to the great improvements introduced in textile machinery by our mechanical engineers and manufacturers. But the net gain is the same, however brought about; and but for this gain in results it is manifest that we could not, in this country, have maintained for so long our superiority as a manufacturing nation. It is true that we have no monopoly of improvements. But we have hitherto, at all events, had a very good start in the race, and if our recent progress has been slower than before we have still made progress, and, in some directions, not a little.

The hours of labour exercise a most material influence on the extent to which a mine, a furnace, or a factory can be made to pay or the reverse. The employer finds that if he can work his factory for twelve hours per day, instead of eight, he will have a very much larger output of whatever commodity he may be engaged in producing. If it is a factory or workshop in which the work is performed automatically—as, for example, a cotton factory, in which the looms and spindles are worked uniformly at the same rate of speed throughout the day—the net result must be a third more work with the same capital expenditure. If it be a factory, on the contrary, where the work is mainly done by manual labour—as, for example, a puddling forge—it has been calculated that the same rate of efficiency is not kept up during the last three hours of the day as in the earlier part, the workmen showing a diminished energy, which is reflected in the reduced value of their output. But as the modern factory system is based on the employment of machinery that is uniformly self-acting, there is not much danger of the production being reduced as in the case last supposed. What is most to be feared in our industrial horizon is the danger that we may be reducing the hours of labour, and increasing the earnings of our workmen, to a larger extent than the increase of efficiency just alluded to will safely permit. The proposal to introduce a general Eight Hours Bill is not unlikely to be mischievous from this point of view.

THE PRESENT POSITION OF THE ALKALI TRADE.

At the statutory meeting of the United Alkali Company, held at Liverpool last week, Mr. T. Robinson, of Widnes, is reported to have said that the wisdom of the whole alkali trade in this country was embodied in its members, and, as the directors have just issued an appeal to the public for the remainder of the authorised capital in this undertaking, it may be of interest to our readers if we devote a little space to considering the present position and prospects of this ponderous undertaking. It is well known that on the termination of the Bleach Association the various makers of soda and allied products by the Leblanc process began a ruinous competition by cutting rates, which had the effect of reducing the market value of their products to a very great extent, and thus caused the closing of many of the smaller works and the partial cessation of others.

In the early part of last year overtures were made by the leading alkali firms in this country to effect an amalgamation, which finally took shape in what is now well known as the Chemical Union. Its present position was summarised by Mr. John Brock, the chairman of directors, in his speech at the statutory meeting of the company last week, and, being official, we may take this statement as fairly representing the position from the promoters' point of view. The authorised capital of the undertaking in capital and debenture stock is £8,500,000, and of this amount the vendors have taken, in part payment of the property turned over by them to the company, stock and shares of the value of £5,391,200, and applications from friends and those interested in the undertaking have already amounted to £1,774,250, making together £7,165,450, and leaving £1,334,550 still to be raised by the public appeal which has been circulated this week. The property acquired consists of forty-five chemical works and three salt works. The company further controls the Leblanc departments of five others and has working agreements with several more. Mr. Brock stated that the plant in the majority of the works was of the most modern construction, and that fifteen of them were now equipped with Chance's sulphur recovery plant. A glowing description of the accessories to the works acquired in the shape of railway stock, fleet, quarries, land, houses, and cottages for workpeople, was also given by the chairman in his address.

So far we have endeavoured to give a sketch of the present position of the undertaking, as gathered from the official statements of the managing director, and have now to consider what the company proposes to do, and the prospects which may be reasonably expected to attend such a scheme. In the prospectus just issued we notice that the directors expect satisfactory returns to the shareholders, not only from the profits on the various manufactures, but from the avoidance of competition, the reduction of transit, economies of management, and increased efficiency of all the manufactories. Moreover, this desirable end is to be achieved without advancing prices unduly—in fact, by maintaining them at such moderate limits as will yield a fair return. We believe that the gist of the whole matter rests on the interpretation of the meaning of the expressions "without advancing prices unduly" and "yielding a fair return," and we would like some information on the meaning which the directors themselves attach to these words. As no goodwill nor promotion money has been paid by the company, and the vendors have valued their own works and been invited to sell their undertakings to the company, not for cash, but for shares and stock in the new company, we can fairly assume that the amount of money which it is proposed to obtain from the public, together with that already supplied by friends of the trade, represents the difference between their own estimate of the value of the property transferred and that which it is supposed to be worth under the new conditions of combination. This difference amounts to upwards of £3,000,000 out of the total capital of £8,500,000, or, in other words, what the manufacturers themselves value, by their own action, at £5,500,000, is to be more than 50 per cent. more valuable now that combination has been effected. It is unfortunate that there are no details as to the profit made by the several undertakings before amalgamation when the old prices ruled. With such data it would have been possible to estimate what would be a fair market value for the products which would give a reasonable rate of interest on the increased capital of the undertaking. The only guide which the prospectus gives us on this point is that the goodwill of all the businesses has in no case been taken into account. We should have imagined that the goodwill of such businesses should have been taken into account, not only by the vendors in transferring their undertakings to the company, but also for the information of the public who are invited to subscribe for the amalgamated business, as it would be a measure of the prospects of "the profits to be derived from the various manufactures enumerated.' It is, perhaps, not for the want of such data that the directors have abstained from predicting what dividends may be forthcoming on the capital of the company.

It is not, however, the financial aspect of the case which especially concerns us, and we do not propose to further criticise the scheme in this direction. Our views on trade combinations of this kind have been expressed on many occasions, and in our recent review of the chemical industries of last year we gave at some length our opinion on the effects that an increase in prices would have on the paper trade and many industries in this country in which the products of the Alkali Union play so important a part.

The effect of the combination on the industry itself must, however, be considered. The United Alkali Company, as we have seen, own forty-five chemical works, and control others making a total of fifty. The Chief Alkali Inspector, in his annual report, states that there are eighty works in England and Scotland manufacturing alkali. There must, therefore, be thirty works outside the Union. Many of these, doubtless, are very small, but they naturally will be in a position to favourably compete against the combination when loaded with its large additional capital. Among the works outside the Union are, however, Messrs. J. C. Gamble & Son and Messrs. Brunner, Mond, & Co., both of which firms are in a position to offer very strong opposition, and we understand that the latter company are already making a very considerable extension to their present large works. With such opposition the new company will have some difficulty in controlling their products at their own "*duly* advanced prices," and at the same time return to their shareholders a satisfactory dividend. They can, it is true, maintain the price at any point by limiting the output, and, if our information be correct, the directors have already decided to take this step, and are reducing the decomposition of salt by 25 per cent., or, in other words, are already admitting that one quarter of their whole plant must remain idle. We are curious to know whether this may not be one reason for not stating the goodwill of certain portions of their works.

One other point, and we have done. Fifteen of the works have been fitted with Chance's sulphur recovery process, and, as is well known, the Leblanc manufacturers have invested practically the whole of their remaining capital in this new venture. The apparatus is exceedingly costly, and, we understand, has taken much time to perfect, and it may probably be estimated that this part of the plant acquired by the company has cost a quarter to a half million sterling. The sulphur recovered by this process, it was hoped, would find a ready sale in America, which country has been importing considerable quantities from Sicily. The McKinley Tariff Act has, however, caused a very serious decline in this trade, and the company will find it difficult to dispose of their 1,000 tons weekly.

In conclusion, we may add that we have purposely abstained from discussing the relative commercial values of the Leblanc and ammonia soda processes, and refrained from speculating on the effect of the introduction of new bleaching agents in the place of bleaching powder, as we wished to put before our readers as fairly as we can the present position of this new trade combination. Mr. Brock let in one gleam of sunshine as to possibilities in the future for the company, when he stated that the directors had determined to open a central laboratory, where they would employ a staff of highly qualified chemists to advise the board on technical matters, and to devise and develop new processes by which the shareholders in the future may eventually benefit. In our recent review we pointed out that the Union could only succeed in one way, and that was by completely revolutionising its means of production—in fact, by gradually transforming its old plant and remodelling its manufactures on the lines of modern progress. We refer again to the Alkali Inspector's report:—"The number of alkali works in which the Leblanc process is carried on still diminishes. Quite recently an old-established work on the Tyne side has been closed. The struggle between the old and the newer process is no longer doubtful." The Leblanc process is dying, and the United Alkali Company, even with its £8,500,000 of capital, cannot prevent it.

THE TAXATION OF MACHINERY.

The opponents of the Bill which has been before Parliament for a considerable time, and has for its object the exemption of machinery from rating, are very active, and are appealing for pecuniary support, both for the purpose of carrying on litigation and for the promotion of legislation which will place the matter beyond dispute, The committee of the National Society for Procuring the Exemption of Machinery from Rating, which was founded some time ago, state that the views and motives of users of machinery have been much misrepresented, and they think it desirable to again explain, by means of circulars and otherwise, the real merits of the question, and to point out the broad grounds upon which manufacturers rely for a successful result to their appeal to Parliament for that redress which the courts of law have so far denied them.

They deny that there is any wish to avoid a fair share of local taxation, but they object to one species of personal property being rated when all other kinds remain exempt. The ground on which the question will be ultimately decided, however, will be the desirability or otherwise of taxing productive machinery. Such a tax acts in restraint of the trade of the country, and by increasing the cost of production hampers English manufacturers in their competition with those of other

Digitized by Google

nations. They maintain that the arguments for Free Trade, and the examples of other nations, are all against the practice of taxing machinery, and they give illustrations from the cases of France, Austria, and the United States. In Austria-Hungary, for example, a law was recently passed to encourage the establishment of factories of all kinds. The advantages offered include the exemption for periods of fifteen years from all local rates, from the house-tax, the mining-tax, and from the taxes on all undertakings compelled by law to publish their accounts, from Chamber of Commerce fees, and from all general additions to the income-tax; also from all fees and local rates on the transfer of factory plots or buildings, from stamp duties and fees on all agreements relating to the founding of companies and on the capital employed by them. The bearing of recent legislation in the United States is also pointed out, as well as the efforts which are now being made for the purpose of inducing English manufacturers to remove their factories to America, for which purpose great facilities are being offered, including exemption from taxation.

COAL DUST IN MINES.

In our issue of the 9th of January (page 36) we directed the attention of our readers to a Minute of the Secretary of State for the Home Department which had been forwarded to Her Majesty's Inspectors of Mines, on the effect of coal dust in causing explosions. The Minute was founded on experiments made by Mr. Hall, one of Her Majesty's Inspectors of Mines, who had come to the conclusion that a blown-out shot may, in the presence of coal dust, and in the entire absence of fire-damp, cause explosions of great violence, often accompanied by volumes of rushing flame travelling considerable distances, and possibly so far as the supply of coal dust continues. He, however, did not think that any fresh legislation could be usefully attempted until the subject, both of the danger which coal dust may cause, and of the means by which that danger can best be met, has been fully investigated by competent scientific men. The Home Secretary has promptly followed up the Minute by arranging for the appointment of a Royal Commission "to investigate and to inquire into the effect of coal dust in originating or extending explosions in coal mines." Mr. Chamberlain has been appointed chairman, and, although he cannot lay claim to special scientific training, he has great business capacity, which is really what is wanted in a chairman. The scientific and practical aspects of the questions involved will lie in the hands of Lord Rayleigh, Sir William Lewis, Professor Dixon, Mr. Emerson Bainbridge, and Mr. Fenwick, M.P. The recent Royal Commission on Accidents in Mines investigated the subject to a certain extent, and had some experiments carried out, and their conclusions were embodied in the Act of 1887. The terrible explosions which occurred last year at the Llanerch and Morfa Collieries, and the experiments by Mr. Hall, however, have shown that there are still many aspects of the problem of explosions in coal mines which require investigation, and that further precautions require to be taken beyond those which are required at present by law. To these the attention of the present Commission will be directed, with the result, we hope, of considerably diminishing the number of explosions. Fortunately, for some time past existing regulations have had this effect; for, although the deaths last year were exceptionally high on account of several severe explosions, during the past ten years there has been a very considerable decrease, the numbers being 1,646, as compared with 2,656 during the previous ten years. For the two decades before that, taking us back to the time when mines became subject to Government supervision, the numbers were 2,267 and 2,441 respectively, so that recent improvement has been very marked. We trust that the work of the Commission may be the means of continuing that improvement.

THE EIGHT HOURS BILL.

The Bill which has been introduced into Parliament by Mr. Cuninghame Graham and other members of his way of thinking, for the purpose of restricting the hours of labour in all trades and industries to eight per day, is one of the most extraordinary measures ever brought before the British Legislature. Its general object and scope will be gathered from its opening clause, which is as follows:—"On and after the first day of January, one thousand eight hundred and ninety-two, no person shall work, or cause or suffer to work, on sea or land, in any capacity, under any contract or agreement, or articles for hire of labour, or for personal service on sea or land (except in case of accident) for more than eight hours in any one day of twenty-four hours, or for more than forty-eight hours per week."

We have on many occasions shown our sympathy with the working classes in their endeavour to shorten prolonged working hours and to effect a general improvement in their conditions, but the measure we have mentioned is so extreme and ill-considered that we feel almost inclined to say, "An enemy hath done this." The proposals are so absurd that they are certain to be laughed out of court. We have faith in British common sense, and we cannot believe that the measure will receive more than very limited support, and that only from the ignorant, or the unscrupulous who take advantage of the working classes. We hope it will be found that the Bill has been so badly drafted that it does not convey the real intentions of its framers, for the meaning which is on the face of it is an insult to the intelligence, not only of men who are expected to frame laws for the country, but also of the great masses of the working classes.

To imagine it either possible or desirable to restrict the hours of labour of all classes, so that, by the beginning of next year, no one will be allowed to work more than eight hours in one day, shows an utter want of economic and industrial knowledge, or a deliberate attempt to throw ridicule on the whole movement. Not only is it forbidden to all to work or cause to work more than the stipulated time, but if any one "suffers" longer hours to be worked he comes in for a share of the penalties. If this means anything at all, it means that when any person finds any other person working more than eight hours per day, he will either by his own influence, or by reporting him to the authorities, cause him to limit his hours. A healthy public opinion on the subject of the hours of labour would no doubt be most effective, but such an effect as that indicated would result in unbearable tyranny. Any measure which proposed to limit hours in those industries which are injurious to health, or where the public safety requires that the workers should always be in good condition, might receive some attention, but one which by a stroke of the legislature attempts to settle the matter for all trades, and for all sorts and conditions of persons, does not even deserve to be seriously considered. The various trades must organise, and, above all, educate public opinion, not only in this country, but also in those countries which are our industrial competitors, and, unless we wish to sacrifice, not only our industrial supremacy, but even our industrial existence, each case must be decided on its own merits, and according to its own conditions. We would only add further, that if the working classes showed a greater desire to fully utilise the leisure they at present have, they would better strengthen public opinion in support of their demands for more.

THE NEW ROUTE TO AUSTRALIA.

Commenting on the new line of mail steamers from England to Australia *viâ* Canada, Vancouver, Honolulu, Fiji, and Moreton Bay, the *Sydney Daily Telegraph* of 31st December, just received, says:—"On the face of it the project seems to have much to recommend it to careful discussion by the Governments concerned. The advantage of an alternative mail route to England, in case of interruption through war or any other cause, to those already in use should be obvious. Such an advantage is, of course, problematical; but the advantage in direct gain of time in the delivery of international mails is certain, and this alone is worth a good deal. With a mail service alternate with those now in operation, and perhaps more rapid, we should be kept in more full and frequent communication with England, to the facilitation and increase of business. But it is in another direction that the greatest gain to ourselves might be confidently looked for. There is a growing desire on the part of the Dominion of Canada to extend her trade to the Australian colonies—a desire which the passing of the McKinley Tariff Act has considerably stimulated. It would be impossible that a line of fast steamers such as has been proposed could travel between Vancouver and these colonies without bringing into existence a great deal of altogether new trade, and developing sources of employment at present almost unknown. It seems to us that the only question to be considered by the Australian Governments in connection with this matter, is whether the probable gain to them by the establishment of the new service would repay the subsidies asked for. No new legislative principle is sought to be introduced, as we already grant subsidies to existing mail services, an arrangement which is admittedly a direct public gain, and has contributed enormously to the development of such magnificent services as we now possess in the P. & O. and Orient lines. Lately, also, the Government of the United States has granted subsidies with a lavish hand to their mail lines, on the ground that the Republic is hereby a gainer, and, although it would not be safe for us to imitate everything which American legislators do under that plea, this case might prove an exception. To subsidise a new line of steamers, which would render us valuable service in opening up new industries and establishing trade relations, would only be an expenditure of State funds similar to that undertaken when railways are built to afford additional convenience to internal production." The pioneer of the connection from Vancouver to China and Japan, the twin-screw s.s. "Empress of India," left Liverpool on Sunday last with a full complement of passengers for her maiden trip around the world, after which she goes on her station on the Pacific.

Letters to the Editor.

CYANIDE OF POTASSIUM AS A SOLVENT OF GOLD AND SILVER.

To the Editor of "Industries."

Sir,—I did not try to prove, as Mr. MacArthur mildly put it in your last week's issue, that his process has been known since 1806.

I claim, on the contrary, to have proved that what Messrs. MacArthur and Forrest call their discovery of the properties of cyanide of potassium as a solvent of gold has been known for many years, and has been described by chemists, electricians, and metallurgists, not only in England, but in France, Germany, and America, and has been the objects of several patents.

Mr. MacArthur complains that, as a scientific and industria periodical, *Industries* ought not to have published such revelations. But if the facts of the case were not known before the publication of my letter, the disclosure I made must be interesting, and *Industries* renders good service in making known the properties of cyanide. Dr. Gore did not mention these properties in his paper, read at the Royal Society, on "Cyanogen as a Solvent," and Professor Crookes, in his last specification, published a few days ago, speaks disdainfully, of cyanide of potassium stating that it has a very feeble solvent action on gold.

I may claim to have elucidated a point of history—viz., that Messrs. MacArthur and Forrest—who speak of the discovery they made after three years of researches and experiments on all sorts of chemicals—have not discovered anything at all.

I did not discuss the validity of their patents, as there is no patent or patentability where there is neither invention nor novelty. Not only did they not discover the properties of cyanide of potassium, but they patented its use for extracting gold from its ores in the same manner as Simpson used it, and for precipitating the gold from its solution, just as Price did—*i.e.*, by means of zinc in a state of fine division.

When Messrs. MacArthur and Forrest and the Cassel Company have refuted my arguments, and proved what they profess, *i.e.*, that cyanide of potassium as a solvent of gold and especially of sulphuretted gold, was not known, and used as such before their discovery, I may give a few more quotations, on the use, years ago, of cyanide in gold and silver mines. For the present Messrs. MacArthur and Forrest and the Cassel Company have enough to do if they try to make researches to demonstrate that I am wrong in my criticism. I do not say that Messrs. MacArthur and Forrest were not *bonâ fide* in believing that they were the first and true discoverers of the affinity, as a solvent, of cyanide of potassium for gold and silver, but after I had substantiated the real facts, as I did in your issue of the 30th ult., it would have been wise to keep silent, instead of indulging in recriminations.

The great point is to use cyanide of potassium as a solvent in a new and original manner, in a new and original apparatus, and to separate the gold from its solution, not only in an efficient, rapid, and cheap manner, but according to a new and unassailable method. I plainly say that I do this by aid of electricity, but if ever the Cassel Company finds that, what I claim to be my invention, is only an infringement or plagiarism, I assure you I will not protest as Mr. MacArthur has done. The Cassel Company has been very unfortunate. At first they took out many patents for a process which everybody knows was not good; and not long ago one of the highest authorities in the metallurgy of gold told me that he had followed the experiments on the old Cassel process, but had never seen one ounce of gold extracted.

Now the Cassel Company has taken out again many patents for extracting gold from its ores, and, this time, the process may be good—I will even say that it is good; but it is based on the extraction and separation of gold by cyanide of potassium, which, I assert, is common property.

Yours, &c.,
Emile Andreoli.

62, Loughborough Park, London, S.W.,
9th February, 1891.

To the Editor of "Industries."

Sir,—Your correspondent, Mr. MacArthur, in his letter last week on the above subject takes exception to the discussion in your columns commenced by Mr. Andreoli in the previous issue. I am not in a position to decide as to which of your correspondents is right in the matter under dispute, but I must differ from Mr. MacArthur in his opinion that a scientific and industrial periodical is scarcely the place in which to discuss the validity of patents. He seems to forget that Mr. Andreoli's letter was prompted by the report in your columns of the discussion which took place at the meeting of the Society of Chemical Industry, at which the process under dispute was subjected to much discussion. As I was present at the meeting I may state that the discussion was apparently taken down in full, and I have received from the official reporter my own remarks thereat, so that I presume that the journal of the Society in its February number will publish the general discussion which then took place on the validity of the patents as hinted by Mr. Vautin and refuted by Mr. MacArthur himself (I believe).

I fail to see the difference which exists between the correspondence in your journal, and the discussion which will appear

THE TAXATION OF MACHINERY.

	GROSS ESTIMATED RENTAL.		PROPERTY TAX.		RATEABLE VALUE.		LOCAL RATES—*i.e.*, POOR, BOROUGH, AND DISTRICT, &c.		Total Increase in Property Tax, Poor, Borough, and District Rates.	Increase per Cent.
	At Present.	If Machinery be Rated.	Now at 8d. in £.*	If Machinery be Rated at 8d. in £.	At Present.	If Machinery be Rated.	Taken at 5s. 8d. in £ on Basis of Rating at 30th June, 1886.	Taken at 4s. 7d. in £ on Basis of Reduction Effected through Increase of Rateable Value.		
	£	£	£	£	£	£	£	£	£	
1. (*a.*) Cotton spinning mills in Bolton, purely spinning..... (*b.*) Cotton spinning mills, having weaving mills, &c., adjoining..... (*c.*) Cotton spinning, silent small doubling, &c., and where number of spindles could not easily be ascertained, are omitted. Rateable value of (*c*) only £1,529, therefore unimportant.	69,603	153,126	2,320	5,104	56,409	124,100	15,983	28,436	15,237	83
2. Cotton weaving, &c., mills, in Bolton	11,709	24,881	390	829	9,556	20,306	2,707	4,651	2,383	77
3. Iron foundries, machine works, &c., in Bolton	18,668	35,319	622	1,177	15,107	28,557	4,280	6,550	2,825	57
£	99,980	213,326	3,332	7,110	81,062	172,963	22,970	39,637		
Memo., on effect of rating machinery now exempt: No. 1 would be increased 120 per cent. No. 2 would be increased 112½ per cent. No. 3 would be increased (except two large works for which allowance is made in calculations) 125 per cent. Property tax would of course be paid on gross increase.			Increase in Property Tax, as above shown, would be equivalent to a 1s. 5d. in the £ tax on present gross estimated rental.				The increase on local rates thus shown would be equal to a 9s. 9d. in the £ rate on present rateable value. That is to say, "rating machinery now exempt" would have the further effect of increasing the mill and works owners' local rates by 4s. 1d. in the £.			

* NOTE.—This Summary was prepared in 1887, when the Property Tax, now 6d. in the £, was then 8d.

The above Table is a summary of a paper prepared for the use of the Select Committee of the House of Commons on the Rating of Machinery, and appended to their Report. This Table takes Bolton as an illustration of the effect which the taxation of machinery, as carried out in the Chard Mills case, would have upon users of machinery in the manufacturing districts of the North of England and elsewhere if it were adopted by the Assessment Committees of those districts.

The Report of the Select Committee above referred to (No. 231) can be obtained from Messrs. Eyre & Spottiswoode, London, price 1s. 6d.

in due course in the Journal of the Society of Chemical Industry. There is, however, a precedent on this very subject, as for some time past the *Engineering and Mining Journal*, of New York, has thrown open its columns to correspondence on the same subject, and Mr. Cuno, who is the chemist of the Gold and Silver Extraction, Mining, and Milling Company in the United States, which owns the exclusive rights to the MacArthur-Forrest process in that country, has himself written a letter on the subject, and thus violated the rule which Mr. MacArthur wishes to introduce.

It seems to me that it would be, in many cases, advantageous if the merits of rival patents could be discussed in a public way in scientific and industrial periodicals, not only as it would afford opportunities for the public to form its own opinion on the points at issue, but in many cases might save the patentees many solicitors' letters, and possibly legal expenses, of a ruinous nature. If a patent is a good one, surely the greater the publicity given to it the better for the patentee.

Yours, &c.,
SAMUEL RIDEAL.

London, 9th February, 1891.

THE TAXATION OF MACHINERY.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Will you be good enough to find space, if possible, for the above table, showing, in a typical instance, the effect on the industries of the country if the new principles of rating premises containing machinery, which have lately been adopted in some parts of the country, were to become universal?

It is most important that the industrial classes, both employers and wage earners, should realise what is in store for them, unless the Legislature can be induced to define more clearly than at present what the law of rating is really intended to include when applied to industrial premises, and, if necessary, to amend the existing ancient Act. The increased burden, as shown by this table, would be intolerable, and manufacturers of all kinds, engineers and others, should at once look into this question, and by every means in their power support the Bills which have been introduced into the House of Commons to avert such disastrous results as are here foreshadowed.

Yours, &c.,
W. H. HOULDSWORTH.

House of Commons, 7th February, 1891.

THE LONDON SMOKE AND FOG PLAGUE.

TO THE EDITOR OF "INDUSTRIES."

SIR,—In answer to Mr. Thomas Fletcher's letter in your last issue, let me say that I do not think his argument will hold water. He says that the difficulty is that asbestos cannot be blackened, because no permanent black is known. I never proposed to blacken the asbestos, but to use a black radiator such as iron, which gets coated with oxide. The appearance may be poorer, but I cannot agree that the efficiency would be less. Black is a better radiator than white, so a given surface will radiate more heat at a given temperature, hence the superiority of gas stoves with iron "fires" compared with those of asbestos. With the same radiating surface the iron radiates more heat, and the burned gases go off at a lower temperature.

As to draught, most gas stoves are provided with no regulators at all. Even if regulators are supplied, it is better to abstract as much of the heat as possible and to radiate it, or even to let it heat the external air by convection or "warm air" arrangements. I have a little gas stove in my office, and I have arranged it with 6ft. of iron flue along one side of the room. This flue gives off nearly as much heat as the stove itself, and the end near the stove is not much hotter than the other, so most of the heat even then passes away in the used gases. If the stove had been connected to an ordinary fireplace, not only would the heat I get from the flue be lost, but there would be a powerful draught up the flue and through every crevice and cranny in the sheet-iron covering of the fireplace.

In conclusion, I must plead that I have had some practical experience with gas stoves, as well as with other industries connected with coal gas.

Yours, &c.,
"LONDONER."

London, 9th February, 1891.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

TO THE EDITOR OF "INDUSTRIES."

SIR,—Allow me to express my appreciation of the thoroughly exact and judicious statement on this subject contributed by Mr. G. R. Bodmer in your issue of the 23rd ult.

The question "Is the study of heat mechanics useful to engineers?" is very much like the other, "Is the study of the habits of growth and the vital forces of plants of use to the gardener?" In any path of life, if you get hold of a *wrong* theory, and allow it to dominate your action, it may lead you very far astray. The other question, "Are the theoretical laws of thermodynamics, as at present understood and taught, true or false?" would be intelligible, and perhaps it might be a useful challenge. But if anything be found wrong in the ordinary teaching, if it be shown to be inconsistent with observed facts, surely that is not a good reason for abandoning the study; rather is it the best of all reasons for devoting ourselves to the study with renewed energy and renewed determination to learn the truth. Even the proof of the incorrectness or incompleteness of the present teaching must necessarily be the result of study of the subject. It would be puerile to dispute the importance to engineers of knowing the truth about the mechanical action of heat—even of knowing it completely. Let us then apply ourselves to the study of this all-important subject, remove all existing errors, and find out the whole truth about it.

It is also ungenerous in those who may have, by the help of our present more advanced knowledge, discovered mistakes in the applications of thermodynamic law (or even in the theory itself) made by the last generation, to sneer at and blame those who made such mistakes. The science was in its infancy, and no doubt mistakes and confusions have been made. We have inherited an immense amount of useful knowledge from these pioneers; it would surely be ungracious to be severe upon them for passing down to us a few misconceptions. What we have to do is to clear these away, if there be any, and above all to *complete* our knowledge of heat actions in the infinite variety of circumstances in which they are clearly of practical importance.

It is a dishonest and contemptible device of the enemies of scientific technical education to assume that engineering professors pretend to turn out "complete engineers" from their colleges. I never met any professor who pretended to do anything of the sort. I believe that we are all conscientious in explaining to our pupils that a formal or informal apprenticeship in works is necessary in addition to the college training. I make this clear to every pupil, and to his guardians as well, before he enters upon the course at Mason College.

Yours, &c.,
ROBERT H. SMITH.

Mason College, 9th February, 1891.

Books Received.

Transactions of the American Society of Engineers, October and November, 1890.

Spons' Engineers' Diary and Reference Book for 1891. London: E. & F. N. Spon.

Reviews.

APPLIED GEOGRAPHY. A Preliminary Sketch. By J. Scott Keltie, Librarian to the Royal Geographical Society. London: GEORGE PHILIP & SON. 1890.

This little book differs from the text-books of commercial geography which have appeared in recent years, and will be found to be useful and instructive to a larger number of readers, as its object is to show what are some of the bearings of geographical knowledge in its application to human interests, to the course of history, and more especially to industry, commerce, and colonisation. The first chapter appeared as an article in the *Contemporary Review*; the other four chapters formed a course of lectures given during the past year at the Bankers' Institute, by request of the council of that body, and were in part re-delivered before the

Digitized by Google

Society of Arts and the College of Preceptors. The first two chapters deal with general data and methods, which are illustrated in the following chapters, with special reference to Africa, the British Empire, and some of the chief commodities of commerce. Mr. Keltie's book will be most useful in giving an idea of the modern methods of teaching geography, and of the wide significance and importance of its study. Ever since Ritter's time a specially human turn has been given to the subject by his countrymen; it has been recognised that the ultimate task of geography is to study the earth as a dwelling-place of humanity. Mr. Keltie points out the bearings of the subject, not only in connection with its wider interests, but also with the more restricted ones of commerce and colonial enterprise. As regards the latter, he shows how foolish were the fears expressed in Britain regarding French and German annexations, and points out the necessity for our public men making themselves better acquainted with applied geography. Mr. Keltie's book will be most useful to such men in at least indicating some of the things they ought to study, but it will also be read with interest by educationists, and, in fact, by all intelligent persons.

Spons' Engineers' Diary and Reference Book for Engineers, Machinists, Contractors, and Users of Steam for 1891. London: E. & F. N. Spon.

This diary, which is printed on good paper, and is well arranged, contains a large number of tables of reference and other useful information. It is prefaced by a report on the engineering trades for the past year, and, besides articles on the amount of work produced by men and by animal power, it contains a properly classified catalogue of recent technical literature, and much information with regard to examination of seagoing engineers, engineering schools, and engineering scholarships.

Asbestos, Its Properties, Occurrence, and Uses. By Robert H. Jones. London: Crosby Lockwood & Son. 1890.

In 1888 Mr. Jones issued, in a pamphlet of seventy-six pages, an account of the Canadian asbestos mines. Believing that in the future there will be few branches of industry in which asbestos will not find a place, he has noted the new uses which are continually suggested. By a careful study of the literature of the subject he has succeeded in giving a synopsis of all that is known of this singular mineral. The literature of asbestos is confined to blue-books, pamphlets, and articles in technical journals. The most comprehensive paper on the subject is inaccessible to English readers, as it was published in the Russian *Mining Journal* in 1886. With this paper the author does not appear to be acquainted.

Mr. Jones divides his subject into thirteen chapters, dealing respectively with the nature and properties of asbestos, its varieties and qualities, the present sources of supply, Italian asbestos and the Italian mines, Canadian asbestos, the Canadian quarries, output and cost of production, deposits in Newfoundland and Norway, application of asbestos to engineering purposes, to military and fire-preventive purposes, and to miscellaneous purposes. The last two chapters are devoted to slag wool and other substitutes for asbestos, and to a description of fibre spinning. The work covers 236 pages, and the text is elucidated by means of some fifty illustrations, many of which are excellent photogravures.

Asbestos, which the author unscientifically describes as a "mineralogical vegetable," is a fibrous variety of hornblende, and differs materially from the so-called asbestos of Canada, which is a fibrous form of serpentine. Its incombustible nature appears to have been known since the time of Moses, and the author gives numerous interesting references to Pliny and other ancient writers, who describe napkins woven of this mineral. Asbestos is chiefly found in the form of veins in metamorphic rocks, and is widely distributed throughout the world, though the finer qualities and richer veins are by no means common. Asbestos of good quality is not found in the United States, and the supplies of crude ore are almost exclusively derived from Canada. Indeed, out of a total export from the Dominion of 3,936 tons in 1888, no less than 3,612 tons was taken by the United States. In Italy mining for asbestos is carried on with greater difficulty than in Canada, and the supply of the mineral, if more abundant, is much more uncertain. When the Canadian mines were opened many mistakes were made, arising mainly from inexperience. Much valuable ground is now covered by waste heaps, which will unquestionably have to be removed when the land is wanted for working, and the cost of this will be enormous. The author points out that this want of foresight will eventually lead to serious trouble at several of the Canadian mines. From the peculiarity of the work there is evidently no other class of mining which so absolutely necessitates the services of a mining engineer to mark out the land in the first instance for mining and for the waste heap. The author anticipates the opening of new mines in Canada, for it has been proved that mining for asbestos, when properly conducted, shows a more steady return for the money invested, with less elements of risk, than mining for any other mineral.

Within the last ten years the use of asbestos in the arts has greatly extended. Its fibre has a strength ranging between that of flax and silk. It is a bad conductor of heat and electricity: it is insensible to the action of most acids and to that of the caustic alkalies, and its specific gravity is low. The preparation of asbestos cloth is rendered difficult on account of the fibres being smooth and free from the irregularities which characterise fibres of animal or vegetable origin. Space will not permit us to enumerate the long list of purposes for which asbestos is used. Whether for closing the breeches of big guns or for rendering cigarette papers incombustible, all the proposed uses of asbestos are fully described by the author. His style tends, perhaps, to be somewhat discursive, and, from the point of view of the general reader, it is to be regretted that the author invariably quotes foreign authors in the original language. It would surely have been better to translate the passages into English. It seems absurd to give the results of an analysis of Canadian asbestos in Italian, as the author has done, merely because he happened to have had the analysis made in Italy. These criticisms are, however, trifling matters. On the whole the work deserves unqualified praise. It is the first English book on the subject, and as a clear description of asbestos and its varied uses cannot fail to make more widely appreciated the useful qualities of a mineral of which very little is known outside the domain of science.

L'Acier. Historique—Fabrication—Emploi. Par L. Campredon. Paris: B. Tignol, Editeur. 1890.

This interesting little book forms one of the series in the "Bibliothèque des Actualités Industrielles," published by M. Tignol, Paris, and a perusal of it shows that it is well worthy of a place among those which have preceded it. A letter to M. Campredon from M. E. Fremy, Member of the Institute, expresses the opinion that the book will bring the author great credit. It certainly gives in a very moderate space a great deal of very useful information about steel, and will be found interesting even by general readers. The first part of the book is taken up with a history of iron and steel from the earliest to the present time. In the second is examined the general properties of metals, and especially of iron and steel, while in the third is given a succinct account of the manufacture of cast and malleable iron. The last and most important part of the work, occupying as it does three-fourths of the book, is exclusively taken up with the study of the manufacture of steel, and with the enumeration of its principal uses. This part will be found thoroughly practical, as it not only describes the main methods and processes of the manufacture, but also gives very good drawings of the furnaces and apparatus used, analyses of the different products, and the properties and uses of the finished materials. A supplement gives an account of the exhibits of steel at the Paris Exhibition of 1889, which, the writer remarks, was a veritable metallurgical panorama, and especially a triumph of iron and steel. On the whole, we agree with M. Fremy that the book is a most creditable production, and will be found useful to a large variety of readers.

A Manual of Public Health. By A. Wynter Blyth M.R.C.S., L.S.A., &c. MacMillan & Co. 1890.

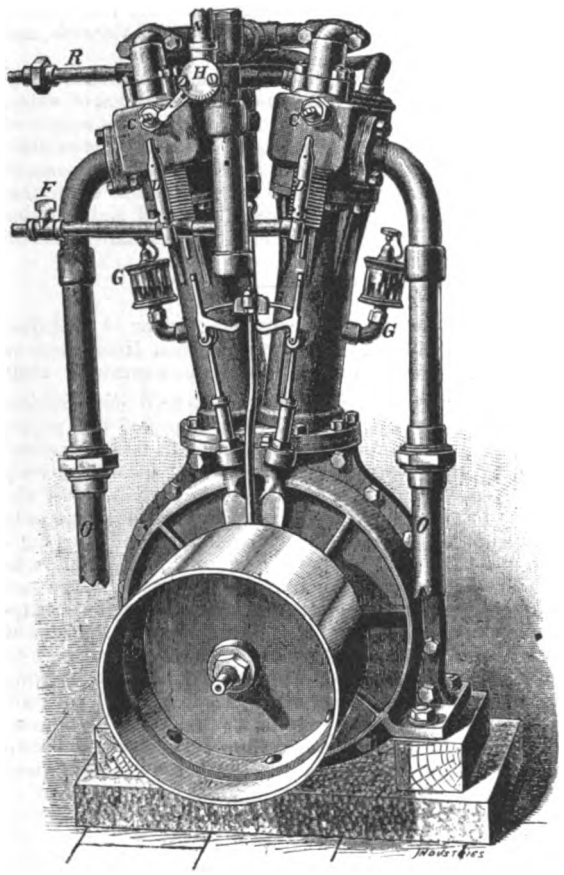
There is no more evident sign of the increased attention which is being given to preventive medicine than the number of text-books which have recently appeared on this subject, and on the various branches of it, and it will soon require some justification when a new manual of hygiene comes out. We may safely say that such a justification exists in the case of the present volume. The chapters on trade nuisances, disinfectants, and infectious diseases would in themselves amply vindicate the author. It is true that these are for the most part compilations from contemporary sources, but they are judiciously selected, and they fill a recognised gap in books of public health. In the section dealing with tuberculosis we miss an account of the well-known fact that light is a powerful agent in the destruction of the spores of tuberculosis. The effect of light in destroying putrefactive organisms was first clearly demonstrated by Dr. Downes, now an Inspector of the Local Government Board. His observations were subsequently extended by other inquirers to individual diseases. It is manifest that this fact has an all-important bearing on the sweeping away of ill-lighted houses in narrow streets, and on the building of the future. It is also a powerful argument for causing smoke from the chimneys of manufacturing establishments to be consumed as far as practicable. We also miss an account of Coenet's valuable researches into the continuance of tuberculous infection in houses and wards. Further, we consider that the evidence relative to the infectivity residing in the flesh of tuberculous cows is not so presented as to lead to unbiassed conclusions. But, in spite of such minor strictures, we think that these matters are, on the whole, fairly presented. We could wish, however, that the names of foreign authors were more correctly given. In other respects the book is well written, and is not loaded with useless material. Another good feature of the book is the list of practical examples given showing how to make calculations, draw up reports on various subjects, make bye-laws, &c. This is deserving of special commendation.

It is, of course, extremely difficult to make such selections from the vast amount of work which has recently been done in connection with the bacteriology and prevention of infectious disease, as will satisfy at once the requirements of every reader, and the dimensions of the present volume. Our reason for criticising this portion of the book is that we regard it as specially valuable, and specially well executed.

Amongst other things which deserve mention we may notice the chapter on the chemical examination of water, Dr. Wynter Blyth's investigations into the action of the halogens as disinfectants, and the well-written little chapters on the inspection of food and on the diseases of animals most frequently met with. On the whole this work is well arranged, very well illustrated, and contains a wealth of material not found in the standard books on public health.

Neuere Wasserwerksmaschinen. Von A. Riedler, Professor au der Königl. technischen Hochschule zu Berlin. Berlin: Verlag von Julius Springer. 1890.

This is a reprint from the *Zeitschrift des Vereines deutscher Ingenieure*, and, like so many of the papers which are read before that institution, it is characterised by German thoroughness, and gives in a comparatively small space a great amount of information about the newer forms of pumps and pumping engines, especially those of German design and manufacture. Its arrangement is descriptive rather than systematic—that is to say, instead of entering into the theory of pumps and pumping engines, it selects specimens and gives descriptions, not only of their general arrangement, but also of their details. The designs which are given are all to scale, and, in fact, could be used almost as working drawings, and thus would be found most useful, not only to students, but also to manufacturers. We do not, however, suggest that students should sit down and deliberately copy them, but rather that they should study them carefully, and observe the good points in them, so that they may be able to incorporate them in any special designs which they may require to make. We have much pleasure in recommending Professor Riedler's contribution to the history of pumps and pumping engines to the attention of those of our readers whose work or studies are connected with these departments of engineering.



Practical Blacksmithing. Compiled and edited by M. T. Richardson. Vol. III. New York: M. T. Richardson. London: Kegan Paul, Trench, Trübner, & Co. 1890.

This is the third volume of a series of books which are made up of articles contributed at different times by skilled workmen to an American publication, entitled *The Blacksmith and Wheelwright*, and covering nearly the whole range of blacksmithing, from the simplest job to some of the most complex forgings. The first volume of the series was devoted to a consideration of the early history of blacksmithing, together with shop plans and improved methods of constructing chimneys and forges. The second was for the most part given up to the consideration of tools, a great variety of which were described and illustrated. The volume before us also takes up the subjects of tool in its first two chapters, after which it is devoted chiefly to a description of a great variety of work, and shows how the tools which were previously described are used practically. We need not attempt to enter into an account of the different kinds of work explained; it is sufficient to say that they cover a very wide field, although special attention is paid to the lighter descriptions. There is to be another volume to complete the series, in which, possibly, the heavier class of work will be described. Although, of course, we do not for one moment believe that blacksmithing is to be learned from books, still there can be no doubt that books can give a great deal of useful information about it. The series we have been considering is possibly the most complete on the subject that has as yet been published, and will be found most useful to a considerable class of readers.

THE "DAIMLER" GAS AND PETROLEUM MOTOR.

Now that gas engine patents are expiring, engineers will naturally turn their attention to the perfection and reduction of price of these motors. For many purposes a high speed is very advisable. It permits of small floor space, less first cost, and for driving high-speed machinery, such as lathes or dynamos, it saves countershafting. For electric lighting, on a small scale, high speed is also very important, as it prevents the flickering due to the explosions, which are often annoying in the case of engines running at about a hundred and fifty revolutions per minute. The slow speed engines also frequently give trouble by shaking, and the foundations have to be very carefully designed to avoid vibration of neighbouring buildings.

The "Daimler" engine, for the illustration and description of which we are indebted to our American contemporary, the *Electrical World*, is specially designed for high speeds. Our illustration represents one of the latest type. It is a 2 horse-power motor, and is only 3ft. 2in. in height; its weight is 300lb., and the normal speed 500 to 600 revolutions per minute. The driving pulley, which is shown in front, is 10in. in diameter, and has a 7in. face. The small floor space which it occupies makes it very suitable for the driving of small dynamos in situations where a larger engine could not be used on account of the limited space. It is used with ordinary gas, or petroleum, as desired, and requires very little attention while running. It is claimed that it can be made ready to start in less than one minute. Engines of this type are manufactured by the Daimler Motor Company, at Steinway, on Long Island, U.S.A., and are coming into extensive use for driving dynamos and for propelling small pleasure boats. The machines are built in 1, 2, and 4 horse-power sizes. In Stuttgart a street car is worked by a 10 horse-power engine of this kind.

THE CHELSEA SYSTEM OF ELECTRICAL DISTRIBUTION.*

THE Chelsea system may be described as follows:—(*a*) Charging the accumulators at high pressure, and discharging for distribution at low pressure, and effecting the changes necessary to the same by special automatic arrangements placed in each storage station; (*b*) supplementing the main supply by means of continuous-current transformers; (*c*) distributing by means of mains laid down in a network; (*d*) maintaining a constant pressure by means of the introduction into the discharge circuit from the storage stations of counter e.m.f. cells; (*e*) the use of underground conductors throughout, laid so that the cables can be drawn in and out, and renewed or repaired whenever necessary, without disturbing the ground.

The arrangements and connections of the charging units, batteries, and transformer motors are as follow:—First, there are three of these plants in series charging one of the half batteries in each of three storage stations, the lighting being maintained by the other, or second half, battery; and the pressure in the distributing mains being regulated by cells which give a counter e.m.f. Second, the three plants are charging the second half batteries. Those which having been previously charging are now discharging to the distribution system. Regulation is still maintained as in the first position. Third, there is a cessation of charging, and the two half batteries are discharging together in parallel. Regulation is maintained as before. Fourth, continuous-current transformers, run by the same units, are supplying current to the system in parallel with both halves of the batteries.

The apparatus for effecting the various transpositions of the secondary batteries in the storage stations, and for maintaining the pressure constant in the mains, is automatic. The movable portions are worked by the energy which would otherwise be wasted in the counter e.m.f. cells, which are used for regulating the pressure in the distribution system. All the actuating portions of the apparatus require current at an e.m.f. of only 4 or 5 volts.

As regards the charging of the accumulators at high pressure and discharging for distribution at low pressure, and effecting the changes necessary to the same by the special automatic arrangements placed in each storage station. The system has worked uninterruptedly in each of the four storage stations now in actual use.

The supplementing of the main supply by means of continuous current transformers is a portion of the system of which our year's experience has gone far enough to show that it is an efficient and reliable way of providing for the increase in demands for current which the full discharge of the distant storage stations would be incapable of meeting; and that the economy arising out of the employment of the generating units, during otherwise idle hours, compensates for the loss in conversion.

During the fifteen months ending with the 31st December, 1890, the growth of the demand has increased up to 19,000 watts. This growth has been accompanied by a variation in the demand according to the season. This variation in the anticipated demand has also been marked by its inequality in various parts of the same district. To provide for such contingencies as this, in the first instance, would have entailed a first outlay in insulated copper, and a consequent idleness of capital, which prudence forbade.

In one case, after eighteen months' full use, it was found, from tests made by the manufacturers, that one-third of the active material of the positive plates had been exhausted. During the latter six months of the same period—which may be considered a good example of normal rate of waste—the peroxide which has scaled off and fallen to the bottom of the glass cell and been removed has averaged half a pound per month from 15 plates, or half an ounce per plate. The general conclusion come to is that under the normal circumstances of charge and discharge of the Chelsea system the life of the brown plates can be calculated at three years at least. The possible leakage from accumulators has been laid some stress on by critics, but, with precautions adopted, the tests on an average show an insulation resistance to the earth of about 50,000 to 100,000 ohms.

As regards the economical aspect of the case, practice shows, in any comparison, that, where a small section of copper in each conductor in the same line only is required, other conditions being alike, it is much cheaper to use insulation of the character of bituminous compound, in ducts, or "ways," of a small size and economical material, than to look for insulation to non-conducting supporting surfaces, with a large surrounding of air space subsisting in a subway of which the minimum first cost must be represented by a substantial figure. It is in connection with large mains that the engineer who has first adopted the use of a dielectric material to surround his copper first turns his attention to bare copper, with a view to obtain a saving in construction. The size of these mains is controlled by the distance between the points of "source of supply" for a given demand in a given area. Obviously, if these points can be placed nearer or further apart, according to what may be called the density of demand, there can be found a fairly definite limit to the size of the largest mains.

But where the "source of supply" is a large generating station, distributing at low pressure direct into a network of mains over a large area, say three-quarters of a mile a side, then I regard the adoption of a system of underground construction, such as that known as Mr. Crompton's, and used in part of Kensington, as unavoidable, owing to the necessity of using stems or feeders of large capacity. Indeed, such a system is the natural outcome of the conditions under which running machinery is the primary, and accumulation is the secondary, source of supply, with low-pressure distribution from one source. On the other hand, when these conditions are reversed, the proximity of the "sources of supply" reduces the section of copper required for feeding the distributing network, and, as I have said, the cost of the underground works is by its simplification much reduced. Also, the position of the generating station is a matter of comparative indifference. Accumulators used in connection with any system which virtually distributes direct from the dynamo at low pressure can be regarded only in the light of auxiliaries, and in no sense as a main force of supply. So far as the author had observed, they act as little more than regulators, and are generally charged and discharged at the same time, and therefore not really fairly treated, and cannot be expected to have an average life.

In Chelsea they had come to the conclusion that, out of five lamps installed in private houses, two represent the maximum number in use at one time, and that we cannot expect that the gross earnings of each lamp installed will exceed 8s. 6d., with the added fact that seventy is the average number of lights installed in private residences. This gives twenty-eight in use at one time, at a cost of a little under £30 per annum at 8d. a unit. The author said this compares unfavourably with such districts as St. James's, but Chelsea is an average residential district, and St. James's is simply the cream of the world.

To help in economising copper, the Board of Trade, in the rules lately issued, prescribe that undertakers shall maintain a standard pressure, which may be different for different portions of a distributing main, and shall declare to any consumer the constant pressure at which they propose to supply energy at his own terminals. Obviously, it is directed that, once declared, that pressure shall not be altered or departed from without authority, except within prescribed limits. These rules go further, however, and say that before using a distributing main the amount of such pressure (which, to meet an obvious condition, may be different for different portions of a main)—*i.e.*, the amount of those pressures—shall be determined, and given to the local authority. Now, with great deference to the Board of Trade, the daily experience in Chelsea shows that this rule, made with the best intention as a help, may be used to bear hardly on a supply company, if enforced to the letter. For instance, take a compulsory street, say with thirty houses along one frontage: a main is laid along it, calculating on a demand, say, from one-third of the houses, and an estimated maximum consumption in each. We don't know really how to proceed under the rule. At first, two houses, at irregular intervals, require current. What are we to declare to them and the local authority before letting them have it? Suppose we declare—what we know will be the case even if five or six houses require a supply—the same pressure throughout. Suddenly the owners of six more houses require current. This demand will at once cause a curve in the line of pressure; and, failing substitution of fresh figures in the declarations to some of the houses, near the centre of the street, which may be those that first came on—a change of intention that would not be easily allowed—or a substitution of a larger conductor, a state of dilemma is produced which neutralises the beneficent effect of this rule, designed for an almost completed system, and not a growing one.

However much a company may desire not to avail itself of the apparent relief afforded by the permission to declare differing pressures, in practice they must do so at points at or near their frontiers. Here we see the effects of Parliament trying to legislate without previous experience.

As regards the comparative cost, generally speaking, if the section of copper in a pair of conductors is 1in. and under, then a main constructed with insulated cables in separate "ways" is cheapest—increasingly so with small conductors. Between 1in. and 1¼in. the comparison varies according to circumstances. Over 1¼in. of section, then uninsulated copper in conduits bears away the prize for economy. Experience in Chelsea enabled the author to give an example of the actual cost of a three-2in.-way line laid in one of the squares. Its length is 613 yards. The cost of supplying and laying the casing, including vestry charges and an allowance for engineering profit, was at the rate of 6s. 6d. a yard. For purposes of comparison, the cost of the surface boxes must be added to the above. Allowing draw-boxes for large angle changes of direction, and one small service box for every two houses, we must add 2s. 3d. per yard, or a total of 8s. 9d. per yard. On the three-wire system—for which provision was, he believed, always made in Mr. Crompton's mains—the three ways in the above example can receive two bitumen high-insulation cables of 61/12, having an external diameter of 1·71in., and one 61/15, with an external diameter of 1·40in. The section of copper in these three cables is 1·335in., and their cost per yard *in situ* is 31s. per yard, giving a total cost of the completed line at less than 39s. 9d. per yard, or if the section was 1·25in., about 39s. This line is sufficient to convey current to all the sixty houses which are situated along the route. If provision need be made for half the houses only, then the cables will cost 17s. a yard, or at a total of 24s. 9d. for the completed main per yard. In actual practice, 324 yards is an unusual length for a distributing main, and the ends of the stems being nearer to one another, the section of copper to supply thirty houses would be actually less.

* Abstract of a paper read on January 22nd, 1891, by Major-General Webber, before the Institution of Electrical Engineers.

ELECTRICAL STANDARDS.

THE following draft resolutions, with others, dealing with the practical measurement of power, whether developed by unvarying or alternating currents, will be submitted to the Electrical Standards Committee for discussion at their next meeting, which will take place on Friday, the 20th inst.:—

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council, as Board of Trade Standards.
2. That the magnitudes of these standards should be determined with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.
3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.
4. That the resistance offered to an unvarying electric current by a column of mercury of a constant cross sectional area of one square millimetre, and of a length of 186·3 centimetres at the temperature of melting ice, may be adopted as one ohm.
5. That the value of the standard of resistance constructed by a committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as ·9866 of the ohm.
6. That a material standard constructed in solid metal, and verified by comparison with the British Association unit, should be adopted as the Board of Trade standard ohm.
7. That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, one or more copies should be constructed, which should be periodically compared with the standard ohm and with the British Association unit.
8. That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0·1) in terms of the centimetre, gramme, and second.
9. That an unvarying current which, when passed through a solution of nitrate of silver and water containing from 15 to 20 parts by weight of nitrate of silver in 100 parts of water, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere.
10. An alternating current of 1 ampere shall mean a current such that the square root of the time average of the square of its strength at each instant, in amperes, is unity.

Digitized by Google

11. That an instrument constructed on the principle of the balance in which, by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by a known weight, should be adopted as the Board of Trade standard for the measurement of one ampere, whether the current be unvarying or alternating.

12. That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

13. That the electrical pressure at a temperature of 62° F. between the poles or electrodes of the voltaic cell, known as Clark's cell, constructed and used in accordance with the specification attached to these proceedings, may be taken as not differing by more than (?) parts in one thousand from a pressure of (?) volts.

THE RECOVERY OF HYDROCHLORIC ACID FROM WASTE PRODUCTS.

The accompanying illustrations represent a side elevation and sectional plan of a hydrochloric acid recovery plant which Messrs. W. J. Fraser & Co., 98, Commercial Road East, London, are erecting under the patents of Mr. Thomas Turner, of Sheffield, for the recovery of acid from waste "pickle." The process is based on the well-known fact that ferric chloride, when heated with air and steam, is resolved into oxide of iron and hydrochloric acid gas. It will be seen that the plant consists of three parts, a specially constructed wasting and evaporating furnace A, a series of cooling and condensing pipes B, and a condensing tower C for collecting the rest of the acid gases. The waste liquor is allowed to run in a continuous stream into the furnace, and is there decomposed, hydrochloric acid gas being given off and oxide of iron being left on the hearth of the furnace. The latter is raked out of the furnace from time to time, and is used for fettling in the puddling process, and for other purposes. The acid condensed is generally of the same strength as that originally used for pickling, and can be used over again for galvanising without any additional treatment. The consumption of fuel is small, being about 4 cwt. per ton of waste liquor treated, and one man is sufficient to attend to the working of even a large plant. The apparatus is constructed chiefly of firebrick, but, as the temperature is never high, the cost for repairs or renewals need not be heavy. Messrs. Walker Brothers, of the Staffordshire Galvanising Works, Walsall, have had a plant capable of treating 10 tons per week in work for upwards of a year with very satisfactory results, and have recently erected a similar and larger plant capable of treating 25 tons per week at the same works, and one for treating 20 tons of waste pickle at Netherton. From their experience of the process, they estimate that 1 ton of hydrochloric acid suitable for re-use in pickling can be recovered at a cost of 8s.

THE INSTITUTE OF CHEMISTRY.

I.

The inception, development, and growth of the Institute of Chemistry is of no contemporary interest, and may be left for the delight of some future biographer. Though originally incorporated under the Companies Act of 1867, the present governing body of chemists in the United Kingdom was of no great importance until it obtained a charter of incorporation in June, 1885, and attained a position approximating to that which is its due. It is with the Institute thus reconstituted that we propose to deal.

It is matter for speculation what proportion of the 780 Fellows and Associates now upon the register have taken the trouble to read critically the charter upon which the Institute of which they are members is based. To those who have not, a careful perusal may be recommended. The weightiest clause therein—but one which, though accepted without comment by all, has scarcely received the attention which it, as indicating the primary object of the existence of the Institute, merits—is to be found on page 6 of the copy of that document, which is supplied to every member on his election. It reads as follows:—

"The profession of analytical and consulting chemistry is one of great importance to the public, and, having regard to the rapidly increasing application of chemistry to legal investigations, to public health, to the adulteration of food (!), to agriculture, and to the arts and manufactures, it is desirable that persons practising the profession of analytical and consulting chemistry should have both a practical and scientific knowledge thereof."

We may parenthetically remark that the "increasing application of chemistry . . . . to the adulteration of food," though undeniable, seems a scarcely sufficiently meritorious practice on which to base a petition for a Royal charter. Having made this remark, we can find no other fault with the tenor of this curious paragraph. It is eminently desirable that analytical and consulting chemists should be professionally competent, and the first business of the Institute is to secure that very essential requirement. It will be seen, both by the phraseology of the quotation made above from the charter, and, by any who cares to look, by reading passages in the rest of the charter, that the whole concern of the Institute of Chemistry is with analytical and consulting chemists as distinct from collegiate and scholastic chemists. It is greatly to be regretted that the title of the Institute was not framed to embody and emphasise this idea. Possibly the clumsiness of a really accurate designation such as "The Institution of Analytical and Consulting Chemists" proved a bar to its acceptance, but, whatever the reason, the less distinctive though broader title has been adopted, and the wisdom of any alteration is disputable. In spite of this verbal defect, the clearness of the intention of the charter is unimpaired, and it remains to be seen in what manner the promotion of the welfare of the profession of analytical and consulting chemistry is to be effected.

After winnowing facts from verbiage, it becomes evident that the institution of a standard of competence with which candidates for membership must comply, the provision of some common meeting place with such adjuncts as a laboratory and library, the endowment of chairs and scholarships, and the establishment of a code of professional morality are the main means by which the character of the profession is to be raised and the standing of its members improved. That the personal behaviour of members, so far as it affects the profession, is a matter coming under the supervision of the Institute, is further shown by the wording of the declaration which each Fellow or Associate has to sign before admission, the last portion reading, "That I will demean myself honourably in the practice of my profession, and to the utmost of my power maintain the dignity and welfare of the Institute."

The foregoing facts bring into prominence the ideas that found expression in the constitution of the Institute of Chemistry, as laid down in its charter, and also indicate its legitimate aims. As to the executive provided for the discharge of its functions, we may be supremely concise: It is the Council. Much is implied by that simple and most ordinary arrangement. As the charter and the bye-laws founded thereon are read, there sinks into the mind of the reader an impression of the immense preponderance of the power of the Council over that of private members. There is, of course, provision for the latter being heard, but the machinery is somewhat cumbrous, and its inertia, together with the apathy that is the besetting sin of the private member everywhere, effectually prevent recourse being frequently had to it. Thus something approaching an autocracy in place of an autonomy results. This is by no means necessarily a disadvantage, but the recognition of the extensive powers of the Council naturally leads to the deduction that any alteration that may be desired in the conduct of the Institute is best effected by exercising the rights of nomination and voting which each

member possesses to bring about a change in the ranks of the Council itself. This point cannot be elaborated here, as it is intended to serve as a text for our second and concluding article.

It is now our duty to examine the present condition and policy of the Institute of Chemistry, in order to ascertain how it has adhered to the ideas and fulfilled the aims upon and for which it was founded. A critic who is in the habit of judging value by utility might be disposed to stigmatise the one as comatose, the other as peddling. We fully recognise the movements which, though scarcely to be termed strides, may be perceived by the careful observer to be distinctly of a progressive character, which have been made within quite a short period of time. The close and sympathetic scrutiny with which we have regarded them has informed us also of their number and variety, and enabled us to conceive an idea of their importance—an importance sufficiently adequate, and which we trust is not exaggerated by the bias of membership which it is difficult for the most impartial to correct. General meetings have been held and adorned with presidential addresses of conciliatory tone, recording the somewhat mild method of progression at present in vogue, and occasionally broaching such weighty topics as the establishment of a widows' fund. Such projects, though eminently benevolent, hardly fall within the province of the Institute, being, indeed, expressly excluded there from by the terms of the charter. Besides these, the Council has sat with much persistency, and achieved some remarkable successes in devising ingenious methods for excluding from the practical examination for the Associateship all those who fail to give evidence of having duly slumbered in the lecture rooms of certain approved colleges.

The members have probably acquired considerable readiness in debate since the recent introduction of a good fighting minority of persons imbued with the idea that the Institute was founded for the benefit of the profession of analytical and consulting chemistry, and not for the indirect subsidising of sundry educational establishments by giving them the monopoly of the training of the coming generation of chemists. Beyond these important achievements there is little to chronicle. The Institute has issued "proceedings," of somewhat meagre and dingy aspect, as often as three times a year, but expenditure in the direction of a journal has been wisely deprecated. Overtures have been made to the Society of Public Analysts to allow itself to be absorbed into the larger body, and thus attain that annihilation which is the ideal of the Esoteric Buddhist, but its Council considered that the reciprocity of the arrangement would be too one-sided to warrant its entertaining the proposal. The most tangible result of the existence of the Institute has been left as an appropriate coping stone to the goodly structure. Subscriptions and entrance fees have been regularly collected, and the salary of the secretary and his clerk punctually paid: *finis coronat opus*.

Notes.

THE CHIGNECTO SHIP RAILWAY.

In our recent articles on the Chignecto Ship Railway we stated that four locomotives of unusual weight and power were being constructed, two of which will be able to move the heaviest ship at a speed of ten miles per hour. We now give some particulars of these tank locomotives—taken from our American contemporary, *Engineering News*—which are being built by the Canadian Locomotive and Engine Company, of Kingston, Ontario. These engines will have eight coupled driving wheels 47in. diameter, and no truck; the total weight in working order will be 180,000lb.; cylinders, 22in. by 26in. The boiler is of the straight top type, 59in. diameter, and contains 256 tubes 2in. diameter. Heating surface of tubes, 1,741 square feet; of firebox, 137 square feet; total, 1,878 square feet. The grate area is 29 square feet. The capacity of the tender tanks will be 3,000 gallons.

RAILWAYS IN ASIA MINOR.

For several years Smyrna, the principal commercial point on the coast of Asia Minor, has had two railway companies who have slowly but steadily extended their lines from that city into the interior. Since last year, states the *Railroad Gazette*, one of these, the Ottoman Railway Company, has opened 117 kilometres of new road, part of this being a prolongation of the main line from Kizil Kaklik to the temporary terminal at Dinair, and the remainder a branch line from Sutledsch to Chivril. The total mileage of this road is now about 280 miles. With the exception of the section between Smyrna and Paradies the roads have only a single track. There are now under construction 30 kilometres of road between Balatschik and Sokia, and between Gondscheli and Denizli, both of which sections are nearing completion. The main line reaches the highlands after leaving Saraiköi, these reaching an elevation of several thousand feet. The present terminal, Dinair, is an insignificant Turkish village of 800 inhabitants, but its good location, it is thought, gives promise of its early development. The other railway, owned by the Smyrna-Cassaba Company, has since last year opened the 54-mile branch from Magnesia to Sorna, and its total length now amounts to 265 kilometres. It is pointed out as a somewhat remarkable circumstance that notwithstanding this growth of the railway systems of the country the caravan traffic has, of late, gained in extent. This is explained by the comparatively high rates, which considerably exceed the cost of camel transportation.

HOWDEN'S SYSTEM OF FORCED DRAUGHT.

We have several times referred to Howden's system of forced draught, and to the advantages claimed for it by its inventor. These advantages are evidently being clearly recognised by steamship owners, as we understand that during last year engines with a total indicated horse-power of 125,520 were fitted with it. In the case of two Allan liners, for example, it was found possible to get the same power from fewer boilers, and the space gained thereby and added to the length of cargo holds was in one case about 65ft., and in the other 70ft. In Messrs. Smiths' line of steamers the system has been largely employed, and with very great advantage and economy, and we understand that now the Inman and International Company have arranged to have the "City of Paris" fitted with Howden's system instead of the closed stokehold as hitherto. This can be done in a comparatively simple manner, involving only some additions and alterations to the front of the boilers. This will be the first high-speed vessel fitted with the system, and it will be interesting to observe the results. The system has now been in operation for some years, and we think the inventor should now come forward and state in a public manner the advantages he claims, and show, from the results of experience, that these are fully justified.

ELECTRICITY IN MINING.

The advantages of the use of electricity in mining operations are gradually becoming recognised in this country, and the most recent instance of its employment for such purposes is to be found in Lancashire, where Messrs. Mercier, Corlett, & Co., of Wigan, have carried out an important lighting installation for Messrs. Richard Evans & Co., Ld. The plant has been laid down for lighting Golborne Colliery (both above and underground), and Golborne Park, where the managing director lives. It is also intended to light the Edge Green Colliery, which also belongs to Messrs. Evans. A Mordey alternator of 2,000 volts and 12·5 amperes is employed, belt-driven from a horizontal engine. For lighting the engine-rooms, shops, and screens, glow lamps of 16, 32, and 50 c.p. are used, while in the yard and sidings there are four 200 c.p. and two 400 c.p. "Sunbeam" lamps. There will be about 100 16 c.p. glowlamps in the two pits. At Golborne Park glowlamps of a total of about 2 400 c.p. have been fitted. The house, stables, offices, and a quarter of a mile drive are furnished with glowlamps. Current is taken from the colliery to the park mainly by overhead wires; but, in passing three streets, the mains are carried underground, and are also underground for about the last half-mile.

ENGINEERING AT CABUL.

An Indian contemporary refers to the work in Afghanistan of Mr. Pyne, an English mechanical engineer, who entered the service of the Ameer in 1887, when his Highness formally asked the Government of India that permission should be accorded to the engineer, whose services he had engaged, to visit Cabul. Leave was granted to Mr. Pyne to go on the distinct understanding that he was proceeding at his own risk. He left Peshawur without any European companions, trusting entirely to his Afghan escort. He was ignorant of the language and customs of the people, but he fared well at Cabul, and the Ameer made known to him, through interpreters, his desire to establish workshops for various kinds of manufactures. Estimates, drawings, and photographs of machinery were accordingly placed before his Highness, who examined them critically, and showed greater knowledge than might have been expected regarding mechanical details. He selected various plants of machinery, including every important essential for the formation of engineering workshops and a foundry. Plant for making rifles and munitions of war, and also such labour-saving appliances as minting machinery, soap and candle machinery, &c., were not overlooked. The Ameer, with characteristic shrewdness, stipulated that nothing should be purchased which Mr. Pyne could not undertake to land safely in Cabul. Hence it became necessary to devise means whereby the heavy machinery could be built up in many small parts, as camels were the only transport means for a great part of the way. The Ameer's workshops are now in full working order under the management of the two English mechanics who went up to Cabul two years after. The mint is turning out a new silver coin of handsome appearance at the rate of fifty a minute, and the cartridge factory has produced a few thousand solid-drawn Martini-Henry cartridges, which are but little, if at all, inferior to those supplied to British troops. The cartridge machinery is not yet in complete working order, but in a year's time it will be finished, and the rate of production will then reach several thousand rounds of ball ammunition per day. Mr. Pyne speaks in the warmest terms of the kindness and liberality with which he and his assistants have been treated by the Ameer.

THE SWEDISH STATE RAILWAYS.

In the course of the year 1889 82 kilometres of fresh line were added to the Swedish Government railways, which, with this addition, reach a total length of 2,613 kilometres. The gross traffic receipts for the year 1889 amounted to 22,201,302kr. (£1,233,405), from which 14,645,166kr. (£813,620) must be deducted for working expenses. The debt incurred in the construction of railways, on which interest was paid for the year 1889, amounted to the sum of 286,390,996kr. (£15,910,611); about 2,000,000kr. of this amount, however, is sunk in lines which are still in course of construction. If this last-mentioned sum be compared with the net receipts for the year 1889 it will be found that they amount to 2·64 per cent. of the total capital. The rolling stock of the State railways consisted at the beginning of the year 1889 of 362 locomotives, 821 carriages for passengers, 63 prison and mail vans, 189 military baggage waggons, 8,603 goods trucks, and 2 waggons mounted with cranes. During the year 11 locomotives, 12 passenger carriages, and 17 goods trucks were added to the already existing stock. The entire number of passengers during the year 1889 amounted to 4,340,222, who travelled an average distance of 45 kilometres per person. The total receipts for passenger traffic were 7,196,790kr. (£399,822), which showed an increase of nearly 97,000kr. (£5,389) on the previous year. The total number of passengers showed an increase of 260,000 in round numbers.

INTERNATIONAL NIAGARA COMMISSION.

The Cataract Construction Company, having invited various firms to send in projects for the utilisation of about 125,000 horse-power at Niagara, and its distribution, partly to an industrial district in the neighbourhood of the Falls, and partly to the town of Buffalo, appointed an International Commission to adjudicate on the plans sent in. This Commission consisted of Sir William Thomson, F.R.S., president; Dr. Coleman Sellers, Professor of Engineering Practice at the Stevens' Institute of Technology, Hoboken, N.J.; Professor E. Mascart, Membre de l'Institut, Paris, and Directeur du Bureau Central Météorologique; Colonel Th. Turrettini, Directeur des Travaux d'Utilisation des Forces Motrices du Rhone à Genève. After a careful examination of a large number of projects sent in, in accordance with the letter of invitation of the Cataract Company, the Commission have awarded the following prizes:—Projects combining the development of power and its distribution.—First prize: Not awarded. One second prize: To the project of Messrs. Faesch & Piccard, Geneva, and Messrs. Cuenod Sautter & Co., Geneva. Four third prizes: To the projects of Mr. A. Hillairet and Mr. Bouvier, Paris; Mr. Victor Popp, Paris, and Professor Riedler, Berlin; Professor L. Vigreux and Mr. L. Levy, Paris; the Pelton Water Wheel Company, San Francisco, Cal., and Norwalk Iron Works Company, S. Norwalk, Conn. Projects for the hydraulic development of the power.—First prize: To the project of Messrs. Escher Wyss & Co., Zurich. Two second prizes: To the projects of Messrs. Ganz & Co., Budapest; Professor A. Lupton, Leeds, and Mr. J. Sturgeon. Projects for the distribution of the power.—No prize awarded.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

26th January, 1891.

1378. Webb, F. W. ..... Steam valves and casing for engine cylinders.
1380. Morrison, J. ..... Looms.
1385. Haigh & Thewlis..... Apparatus for drying animal or vegetable fibres.
1387. Anderson, R. W. ..... Lubricators.
1389. Douglas, J..... Valves and valve gear for steam engines.
1391 Wild, J. ..... Steam traps.
1410. Woodward, J. ..... Machinery for charging and drawing gas retorts.
1414. Croasdell & Hall ..... Friction clutches.
1418. Lanz, H. ..... Thrashing machines.

27th January, 1891.

1436. Frazer & Cosford ..... Reversing gear for steam engines.
1437. Wilcox, S. ..... Compound steam engines.
1447. Weatherhogg, G. W. ... Gas and hydrocarbon engines.
1463. Atkinson, F. A..... Railway points and signals.
1467. Dawson, Dawson, & Stott ..... Inking apparatus of letterpress and lithographic printing machines.
1478. De Benjumea, J. D..... Steam boilers.
1485. Greenhough, J..... Rotary engines.
1496. Dureya & Barker ..... Type-setting machine.
1497. Flohr, O..... Automatic railway couplings.
1498. Flohr, O..... Friction clutches.
1502. Sutton, J. ..... Pumps.
1509. Lake, H. H..... Filtering apparatus (*Knight*).
1520. Böttger & Zeunert..... Apparatus for removing waste from carding machines.
1521. Lake, H. H..... Filtering apparatus (*Knight*).

28th January, 1891.

1536. Duke, A. ..... Tramcar stopping and starting gear.
1540. Webb, W. H. ..... Compression pumps.
1551. Noton, W. ..... Spinning and doubling machinery.
1558. Birch & Lowe ..... Lathes.
1570. Worsdell & Threlfall Balanced slide valves.
1581. Haddan, R. ..... Engine governors (*Passburg*).
1586. Schlepitzka, A. ..... Rock drilling machines.

29th January, 1891.

1598. Thomson, Sir W. ..... Turbine water wheels.
1601. Whittaker, T. ..... Presses for making bricks and other analogous articles.
1609. Ellison, J. ..... Self-acting loom feed.
1610. Broun, J. E. ..... Excavating scoops.
1630. Winchester, J. C. ..... Piston rings or piston valves.
1633. Jackson, W. ..... Winding and spooling machines.
1636. Foot, E. M. ..... Stored explosive power machine.
1653. Robson, R. ..... Steam boilers.
1655. Murgatroyd & Murgatroyd ..... Looms.
1662. Edwards, D., Jun. ..... Lifts or hoists.
1675. Reynolds, E. ..... Apparatus for moving and turning heavy forgings.

30th January, 1891.

1689. Lanchester, F. W. ..... Igniters for gas engines.
1690. Taylor, Taylor, & Taylor ..... Loom picking apparatus.
1694. Clerk, D..... Starting gear for gas engines.
1696. Harbinger, W. ..... Marine boilers.
1698. Duffield, C. ..... Tunnelling machines.
1717. Oxley & Sellars ..... Pressure filters.
1719. Russell, E..... Railway signalling apparatus.
1720. Rowland, T. ..... Cranes.
1721. Munns, W. H. ..... Railway car brake (*Zimmermann, Jun.*).
1723. Weckauf, J. ..... Roller mills for grinding paint, &c.
1724. Landiss & Jenner ..... Thrashing machines.
1735. Fletcher, B. M. ..... Means for governing steam engines.
1744. Lake, H. H..... Steam boilers (*Lorillard*).
1746. Società per l'applicazione dell' aggancia-tore automatico Prada Pietro Prada & Co..... Car coupling.
1756. March, L. R. ..... Liquid meters.
1757. Herzog, C. ..... Liquid meters.

31st January, 1891.

1756. Vickerman, J. ..... Weft stop motion for looms.
1762. Wallis, J. E. ..... Machine for pecking and loosening the surface of roads.
1770. Cockshott & Holden ... Stop-rod mechanism of circular box looms.
1780. Clerk, D..... Gas engines.
1784. Richardson, H. W. ..... Friction clutches.
1787. Taylor, R., Jun. (of the Firm of Asa Lees & Co., Ld.) ..... Cone driving mechanism.
1805. Lishman, T. G. ..... Steam boiler furnaces.
1867. Horn, W. W. ..... Car coupling (*Ventress*).

ELECTRICITY.

26th January, 1891.

1390. Boehm, E. ..... Incandescent lamp.
1396. Newton, F. M. ..... Arc lamps.
1425. Boult, A. J. ..... Storage batteries (*Roberts*).

27th January, 1891.

1432. Bollé, C..... Manufacture of carbon filaments for incandescent lamps (*Keen*).

29th January, 1891.

1680. Tavernier, A. E. ..... Manufacture of wire for transmitting electric currents.

30th January, 1891.

1741. Howard, H..... Apparatus for electric welding.

31st January, 1891.

1779. Hartnell, W. ..... Motors and dynamos.
1804. Redfern, G. F. ..... Electric motors (*W. Lahmeyer & Co.*).

CHEMISTRY.

30th January, 1891.

1737. Imray, O..... Colouring matters (*Die Actiengesellschaft für Anilin Fabrikation*).
1742. Pitt, S..... Manufacture of a new amidonaphtolsulphonic acid and colouring matters therefrom (*L. Cassella & Co.*).

31st January, 1891.

1785. Meyer, E. ..... Production of aluminium.
1818. Winder, J. B..... Preparation of soluble bichromates and sulphuric acid for use in voltaic batteries.
1824. Lifschütz, I. ..... Production of cellulose and oxalic acid from vegetable fibrous substances.
1825. Lake, H. H..... Manufacture of carbonate of soda, carbonate of potash, hydrochloric acid, and chloride of lime (*Letellic*).

MISCELLANEOUS.

26th January, 1891.

1401. Hunter, E. S..... Chain pipe wrench.

27th January, 1891.

1455. Bohm, W. D. ..... Pipe coupling.
1466. Asbury, J. ..... Adjustable screw wrench.
1505. Elliott, Blackstock, & Blackstock ..... Nut locks.
1514. Cooke, W. ..... Nut lock.

29th January, 1891.

1629. Earp, W. R. ..... Boiler anti-incrustation compounds.

30th January, 1891.

1703. Fraser, W. ..... Hose pipe connection.
1704. Warrington, H. ..... Kilns for burning bricks, &c.
1747. Bowles, J. ..... Saws.

31st January, 1891.

1782. Tapscott, R. L..... Lock nuts.
1791. Richardson, J. C. ..... Nut locks.
1819. Summerskill, C. W..... Automatic fire-extinguishing sprinkler.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Machinery for Charging Gas Retorts.—*J. C. Chandler, London.*—The invention relates to apparatus for charging inclined gas retorts, and is constructed as follows:—At a suitable height from and in the same vertical plane as the charging end of the gas retorts are fixed two rails, on which run wheels supporting a framework for carrying the charging apparatus. This charging apparatus is in the form of a hopper, provided with a gas valve at each end, the lower end of which is shaped to fit the charging mouth of the retorts. The hopper is so fixed in the framework that it can be moved transversely and raised and

Digitized by Google

lowered so that its lower end can be caused to enter the charging mouth of the retort in the following manner:—At each end of the framework is fixed a rail at right angles to the rails on which the wheels of said frame run. Running on these rails are two grooved rollers revolving on suitable studs at each side of the hopper. These studs are fixed eccentrically on two discs carried on a spindle passing through and supporting the hopper. The grooved rollers may thus be caused to revolve on their studs, so moving the hopper transversely, which hopper may then be raised or lowered by revolving the supporting spindle by means of a lever-handle, as will be understood. To charge the retorts the upper valve of the hopper is opened and the hopper charged with coal. This top valve is then closed and the hopper brought over and its lower end inserted in the charging end of the retort. The valve at the lower end of the retort is then opened, as also is the valve in the end of the retort. The coal is thus allowed by gravity to descend into the retort. Four claims are made.—No. 9394. June 17th, 1890. 8*d*.

NAIL MAKING MACHINERY.—*J. W. Ells, Pittsburg, Pennsylvania, U.S.A.*—The invention relates to the production of "hob-nails," or those having large protuberant heads. Fig. 1 in the accompanying illustrations is a plan, Fig. 2 a sectional elevation, and Fig. 3 is an enlarged section of the mechanism for forming the nails. Mounted in bearings upon a frame A is a transverse driving shaft B having two cranks C C^1, the latter of which has the greater "throw." Connected by connecting rod D to C is a slide E, working in a suitable slide way, in which is fixed the male die F. In a central hole in F is a stationary rod F^1 (Fig. 3). Opposite E is a head G, in which works a female die H, behind which is a slide I capable of a slight movement. This slide I is of a T-shape, and one arm I^1 is connected by a rod J to the slide E. Working through H and I is a rod K fixed to the end of a rod L running in suitable bearings and normally held forward by a helical spring M. Fixed to L is an arm L^1 which works in a slotted rod N actuated from eccentric C^1. Fixed also to L^1 is a rod O having a notch in its under side, which, when the rod L is forced backwards, so compressing the spring M around it, the

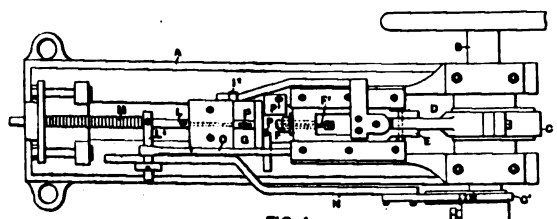

FIG. 1

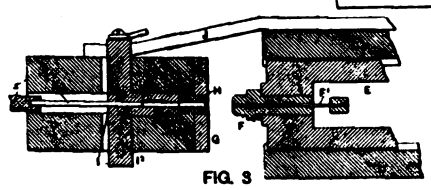

FIG. 3

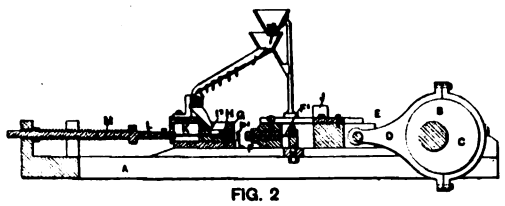

FIG. 2

notch embraces the arm I^3 of I, so holding L until I commences to move backwards when it is released. The action is as follows:—The hot bar of metal is fed between the two dies, being regulated by two stops P P^1, and as F moves forward a piece of metal is cut off sufficient for the head of the nail to be formed. This metal is forced into the female die H, which is then caused to recede, so releasing L, which had previously been forced backwards. L and K are consequently forced forward by the spring M, and passing through I and H, force a shank which has been previously formed and fed into a slot I^3 in I by a suitable apparatus (Fig. 2) nearly completely through the head previously pressed. The whole of the parts then return to their normal position, the nail thus formed being released by the action of the rod F^1. Twelve claims are made.—No. 16547. October 17th, 1890. 8*d*.

PRESSURE GAUGES.—*W. E. Heys, Manchester. (Schäffer & Budenberg, Buchau, Magdeburg, Germany).*—Steam pressure gauges constructed according to the present improvements contain a concentrically corrugated diaphragm, as in the ordinary "Schäffer gauge," but this, instead of being placed horizontally as hitherto, is arranged vertically, so that the steam may have access to the back thereof. In front of this diaphragm is pivoted, in a slot in the casing of the gauge, a bell-crank lever, one arm (in the form of an adjustable screw) of which bears upon the centre of the diaphragm. The other arm (also in the form of an adjustable screw) passes through a slot in a sliding bar, one end of which is connected to a crank pin secured upon the index-finger spindle. Consequently the motion of the diaphragm is communicated through the bell-crank lever, the sliding bar, and the crank pin to the index finger. In front of the sliding bar is fixed a bar having a longitudinal slot in it, in which slot that end of the bell-crank lever which passes through the sliding bar works, and which so prevents the lateral motion in the bell-crank lever. A helical spring, one end of which is fixed to a fixed hook in the framework, and the other end to a hook or sliding bar, tends to keep the latter in its lowest position. Claims: (1) A pressure gauge constructed and arranged as described; (2) in a pressure gauge having a vertical diaphragm, the combination and arrangement of an angle lever provided with an adjusting screw, a sliding bar operated by the angle lever, and a crank pin mounted upon a plate fixed to the index finger and connected to the sliding bar as described.—No. 19896. December 6th, 1890. 6*d*.

GOVERNORS FOR HIGH-SPEED ENGINES.—*J. Wild, Oldham.*—Fig. 1 in the accompanying illustrations is a vertical section of a governor constructed according to this invention, Fig. 2 being an improved method of gearing. The standard A supports a hollow pillar B, revolving on which is a block C having fixed on its under side the gear wheel D. This wheel gears with the wheel E, actuated as shown. Formed on C are two ears C^1, to pins passing through which the lower ends of the rods F F are pivoted. The block C is prevented moving longitudinally on B by means of a flange B^1 on the latter. On the upper end of B, free to revolve and slide up and down, a threaded nut G is placed; upon this nut a cap H is screwed, having lugs H^1, to pins passing through which are pivoted the upper ends of the rods F^1 F^1. The opposite ends of the rods F F and F^1 F^1 are hinged together and carry between

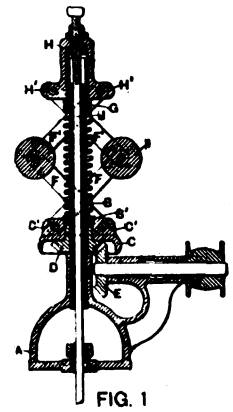

FIG. 1

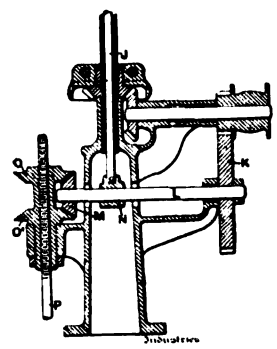

FIG. 2

them balls or weights I as shown. Between the blocks C and nut G, and encircling the pillar B, is placed a suitable spiral spring. Screwed into the top of G, and passing downwards through B and A, is an adjustable rod J, which is connected to the valve regulating the supply of steam to the engine. When very steady running is required the gearing K (Fig. 2) is employed to drive the shaft L and with it the bevel friction M. The rod J is then connected to the sleeve N, so that when the governor rises or falls the bevel friction gear M is brought into action, thereby causing the whole to revolve in one direction or the other, thereby raising or lowering the screw P which may be connected either to the throttle valve or cut-off motion of the engine to be governed in any convenient way. Claims: The crossing of the bottom pairs of arms; the employment of a regulating nut or bush; the screwed spindle and lock-nut and ferrule; the employment of friction gear for the purpose and in the manner described and illustrated, and the general arrangement of governors for steam or other motive power engines.—No. 448. January 10th, 1890. 8*d*.

CRANK BENDING MACHINERY.—*C. Cousins, Broadgate, & H. Clarke, North Scarle, both of Lincolnshire.*—In the annexed illustrations Figs. 1 and 2 are elevations showing the parts respectively in their raised and lowered positions, and Fig. 3 is a horizontal section of the improved apparatus. A is the solid block which is shaped to the form of the crank required to be produced, and to each side of this block a guide plate B is rigidly secured by bolts and nuts B^1. C is the upper block capable of being moved vertically up and down by steam or hydraulic power, and guided in its movements by ribs C^1, formed on both of its sides, which enter and work in grooves formed in B D are the adjustable rectangular blocks carrying pins D^1, which project into and work in the slots B^2 formed in the guide plates. To each of these blocks a pair of links E are pivoted at E^1, and the other extremities of the links carry adjustable rollers or rolling blocks E^2, working in slots E^3. When a bar or rod is to be cranked, the upper block or crosshead is first raised and the adjustable blocks D are turned by means of a suitable tool, inserted through the

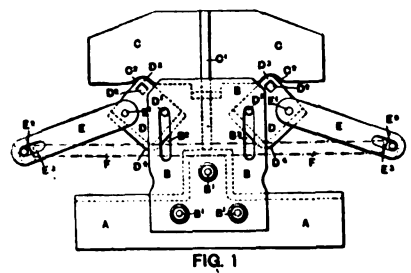

FIG. 1

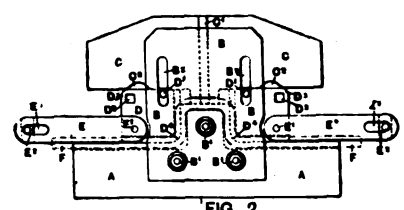

FIG. 2

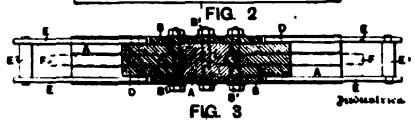

FIG. 3

holes D^2, so as to bring their rounded corners D^3 into the depressions C^2 formed in the upper block. The bar F, having been previously made hot, is placed in the machine in the position indicated by dotted lines (Fig. 1), and the adjustable rollers E^2 are then caused to press firmly against the ends of the bar. The upper block or crosshead is now caused to descend, and the lower corners D^4 of the adjustable rectangular blocks are pressed against the bar F, thereby gradually bending it to the required shape. These adjustable blocks during their descent also turn about their pins D^1, and thus keep the rollers carried by the links E held against the ends of the bar or rod during the early part of the bending operation. Two claims are made, embracing the method and machine for bending cranks substantially as described.—No. 3435. March 4th, 1890. 6*d*.

ORE CONCENTRATORS.—*P. M. Justice, London. (J. S. Brownell, San Francisco, California, U.S.A.).*—This invention relates to ore concentrators in which an endless travelling belt having raised flanges or edges is used. Such belts travel around drums and rollers so as to form a constantly moving bed or plane on which the washing of ores is effected. The object of the invention is to prevent the flanges of such belts when passing around such rollers from becoming cracked owing to the strain thus put upon them. This the inventor effects by employing a fluted or waving line or fulness of flange, which, in passing around a roller, simply straightens out somewhat, and without causing any undue tension or stretching of the material composing the flange. Claims: In a travelling belt having flanges—(1) The employment of a greater length or fulness of material in the upper edge of the flange than in the lower; (2) a flange having a waving, scalloped, or channelled outline; (3) a flange of greater total length than the sides of the belt to which it is attached, as described.—No. 11177. July 17th, 1890. 6*d*.

LEAD PRESSES.—*C. C. Tracy, Brooklyn, U.S.A.*—The invention relates to the dies of lead presses designed more particularly for covering wire with lead, and for making S traps. In the annexed illustrations Fig. 1 is an elevation of an ordinary hydraulic press, the improved die being in section; Fig. 2 is a sectional plan thereof, Fig. 3 being a detail. Mounted on the ram A is the die block B. In a curved seat B^1 in B is fitted the tubular die C formed with side openings C^1, and at one end with a shoulder C^2 and with the conical core D. The tapered end of D is coincident with the die ring E held by the shoulder C^3, the exterior diameter of D being slightly smaller than the interior of E to allow of the passage of the lead. If wire is to be covered D should be hollow, but if piping is to be formed it must be solid, as shown in Fig. 3. Over the tubular die tube C is

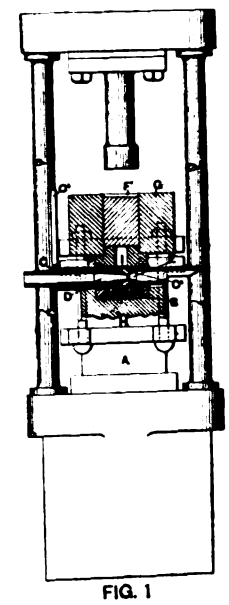

FIG. 1

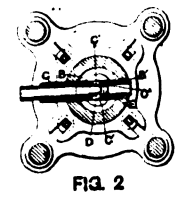

FIG. 2

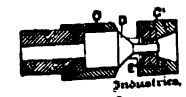

FIG. 3

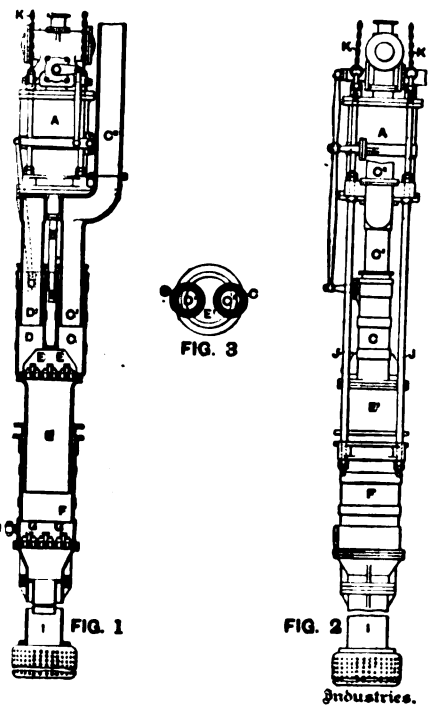
placed a cap F, centrally apertured at F^1 to coincide with the openings C^1, upon which is placed the hollow top block G, held in position by bolts engaging slotted lugs thereon, and in base block H. The die C is adapted to be turned axially in its seat by a lever C^3 to shift the division piece or bridge I to the right or left to increase or to diminish the flow of lead at either side of the tips to prevent "buckling" or to form a curve as required. Ten claims are made, embracing the arrangement as described, with modifications.—No. 10147. July 1st, 1890. 8*d*.

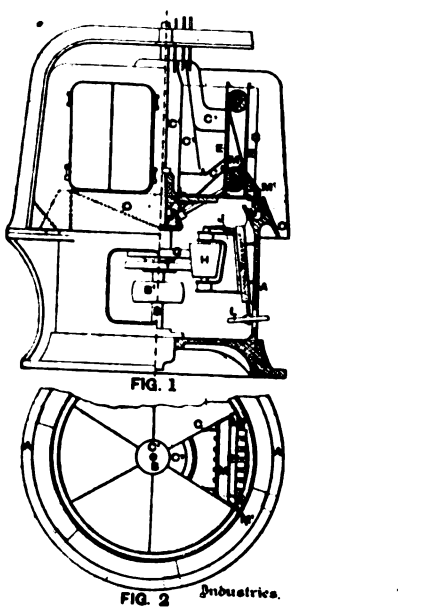


TOOL HOLDER FOR LATHES.—*H. B. Lee, London.*—The holder constructed according to this invention consists of a bar or tube of steel, or other suitable metal, of a square or round cross-section, and having formed in it a longitudinal hole extending nearly through the whole length thereof, one end, however, being left solid. Through this solid end, and passing through the end of the longitudinal hole, are cut holes or slots of a similar section to the cutters used, and in a direction diagonal or at right angles to the bar, and obliquely in the vertical plane. These holes are cut from both sides of the holder, so that cutters may be inserted from either side. At the rear end of the holder a screw thread is formed in the bar, into which is fitted a set screw. This screw presses upon the end of a loose bar, placed in the longitudinal hole; the other end, which is cut obliquely, presses against the cutters placed in the diagonal slots, so that the cutters may be rigidly fixed by tightening up the set screw. A small pin, fixed to the bar in the longitudinal hole in the holder, works in a longitudinal slot in the latter, so preventing the bar from revolving. Three claims are made, embracing the general construction and arrangement of a tool holder for lathes, planing, and similar machines, substantially as described.—No. 16525. October 17th, 1890. 8*d*.

JACQUARD MACHINES.—*F. & A. Mortimer & W. Wright, all of Gomersal, near Leeds.*—The invention relates to the counterpoise harness in jacquard machines where the bottom or "hole" board of the machine is depressed at the same time that the lifting knives or "griffe" is raised. The "griffe" is connected by a suitable rod to the ordinary lifting lever. Pivoted at each side of the machine near the top thereof are two levers of the first order. The outer ends of these levers are connected by means of suitably bent rods to the bottom board, and the inner or opposite ends are connected to the rod connecting the "griffe" with the ordinary lifting lever. Each end of the "hole" or bottom

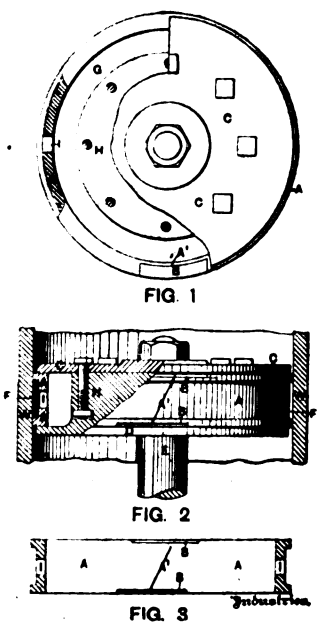
Digitized by Google

board slides in grooves inside the frame of the machine. By the above arrangement it is obvious that as the "griffe" rises the bottom board will descend and *vice versâ*, and so one portion of the harness will balance the other. To prevent the loom recoiling or turning back on being stopped a cam is placed on the driving shaft thereof on the surface of which slides a catch pivoted to the side of the loom. Claims: (1) The raising and depressing of the bottom board of the jacquard machine in the manner described; (2) the arrangements and combinations as set forth.—No. 2807. February 21st, 1890. 6*d*.



PUMPING ENGINES.—*W. H. Bailey & G. Lindemann, both of Salford, Manchester.*—The invention relates more particularly to those pumps in which a ram in combination with a steam cylinder is used such as in sinking pumps. Fig. 1 in the annexed illustrations is a sectional elevation, Fig. 2 an elevation of a pump for well sinking to which the invention is applied, Fig. 3 being a sectional plan. A is the steam cylinder, in which works the piston rod B, and to which are secured the pump barrels or cylinders C and D, having the hollow ram E^1; E are the lifting valves; C^1 and D^1 are hollow pistons or guides secured to or near to the bottom of the cylinder A; the piston C^1 forms part of, or is connected to, the discharge pipe C^2, and the piston D^1 forms an air vessel; the pump barrels C and D slide on the pistons or guides C^1 and D^1, which together constitute well-balanced guides and enable the pump to work smoothly and without side strain. F is the pump cylinder in which the ram E^1 slides; H is the snifting valve and G are the lifting valves at the bottom of the cylinder F; I is the inlet pipe, J are tie rods which connect the pump cylinder F to the steam cylinder A, and K are chains by which the pump is suspended. The mode of operation is as follows:—When steam is admitted to the cylinder A the piston B moves downward and carries with it the pump barrels C and D and the hollow ram E^1, the valves E lifting; when the piston B, barrels C and D, and ram E^1 rise, the valves E are closed and some of the water above the valves E is discharged through the pipe C^2.

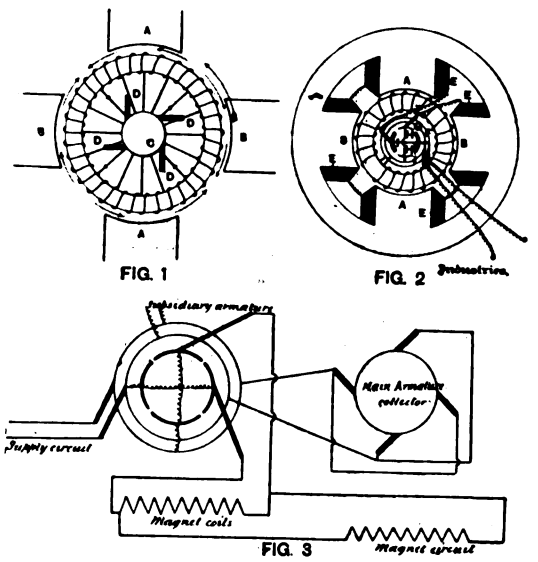
The snifting valve H admits air into the pump barrel F as usual, and a portion of the said air finds its way to the air chamber in the hollow piston D^1. Claims:—(1) In pumps and pumping engines the combination with the hollow piston or guide which forms part of the discharge pipe and on which the pump barrel slides of an additional guide on which the pump barrel also slides; (2) the combination with the hollow piston or guide which forms part of the discharge pipe and on which the pump barrel slides of a hollow piston or guide which forms an air chamber and on which the pump barrel also slides, as and for the purposes described.—No. 1192. January 23rd, 1890. 6*d*.



CUPOLA FURNACES.—*C. A. Sahlström, London, & A. F. Hill, West Brighton, Sussex.*—According to this invention, which relates to furnaces in which hydrocarbon fuel is used, the lower portion of the furnace is enlarged, and made with a dome-shaped roof, through which, and at about the centre thereof, the flue or upper portion of the fire chamber, arranged at an angle of 60° or 45°, communicates. The top of this angular portion is in communication with a flue, preferably vertical, in which is arranged a coil of steam pipes to superheat steam to be utilised for the supply of the hydrocarbon burners, which are inserted in the enlarged portion of the fire chamber and project downwards therein. The burners are capable of adjustment in these tubes, so that they may be kept at such a distance from the metal in the furnace that the fuel may be converted into vapour before striking said metal. There is a charging door at the top of the angular fire chamber, with sight hole and a platform for facilitating feeding and attending. The brickwork of which the cupola is constructed is cased on the outside with iron, and on the front side there is an air space or chamber between this brickwork and iron casing, to which air is admitted at the upper part, which, being caused to circulate through the said chamber, is utilised at the base for the hydrocarbon burners. Four claims are made, embracing the general construction and arrangement of cupola furnaces, as described.—No. 2070. February 8th, 1890. 8*d*.

CENTRIFUGAL MACHINE.—*J. Imray, London.* (*La Société Nouvelle des Raffineries de Sucre de St. Louis, Marseilles, France*).—Fig. 1 in the annexed illustrations is a half part sectional elevation, and Fig. 2 a plan of an apparatus constructed according to this invention. Running in bearings in a suitable framework A is a vertical shaft B driven from B^1, and carrying the centrifugal casing or revolving drum. The casing is divided into six or more compartments C (Fig. 2). At the front or outer edge of these compartments are placed the rollers D D^1, over which runs a filtering web E, being driven by means of a gearing F fixed to a loose collar G on B. This loose collar gears with a conical drum H, which in its turn gears with a wheel I keyed on B. The wheel H is carried in a frame J sliding on a slide K set

at an angle as shown, so that although H and J may be raised or lowered by means of screw L in the ordinary manner to alter the speed of E as desired, H will always be in gear with G and I. Inside E is a casing M connected by pipe M^1 to an annular groove N in A. The inner side of M is perforated. The revolving drum compartments C are each divided into four divisions C^1 C^2 C^3 C^4 (Fig. 1). To the top of C^1 C^2 C^3 are connected pipes which supply respectively water, the material to be treated, and steam thereto. The water passes down C^1 through openings in the bottom thereof into C^4, and so against and through E into M and away. The material is fed into C^2, and passing down, it strikes a reflector as shown, so striking E, and is washed by the water from C^4, which is carried up so far by E before passing through it. The material is then carried upwards by E, and, after being acted upon by steam supplied to C^3, is thrown against a casing surrounding the drum, and escapes through an opening O. Claims: (1) The centrifugal machine, having for its filtering surface a vertically travelling web, against the inner face of which is projected the matter to be treated, and also, if necessary, cleansing liquid and vapour, and from the outer face of which the solid portion of the matter treated is projected into an outer casing, whilst between the faces the strained-out liquid is collected and run off; (2) in a centrifugal machine, such as is above referred to, the gearing for driving the travelling filter web at suitable and adjustable speed, consisting of the roller D^1, the spindle B and its bevel pinion, the wheels F, the conical drum H adjustable in position, and the wheel I, substantially as described.—No. 2774. February 20th, 1890. 8*d*.



STEAM ENGINE PISTONS.—*G. Twigden, Cardiff.*—Referring to the accompanying illustrations, Fig. 1 is a plan, partially in section, of a piston arranged and fitted in accordance with this invention, Fig. 2 is a part elevation and part section, and Fig. 3

is a section of the piston ring. The piston packing ring A, split diagonally at A^1 and provided thereat with tongue pieces B, is contained between the junk ring C and the flange D of the piston. The ring A, which has play between the junk ring C and the piston flange D in the line of the axis of the piston rod E, is flanged at top and bottom. The flanges bear against the interior of the cylinder wall W (Fig. 2), and an annular space F, closed at top and bottom by the flanges, is thus obtained between the body of the ring and the cylinder. Communication between the space F and the space G existing between the body H of the piston and the internal face or back of the packing ring A is established by an aperture or apertures I in the body of the ring A. The ring A being free to move axially, as aforesaid, it follows that when the piston is moving, say, in a downward direction, the ring is, by the pressure of the steam behind the piston, kept away from the junk ring, and, consequently, an opening is left all around between the junk ring and the packing ring, by which opening steam has access to the space G. Thence by the aperture or apertures I in the ring A the steam is admitted to the space F. On the reverse stroke of the piston the ring A is forced against the junk ring, and thereby an opening for the steam is presented between the ring A and the piston flange D. Thus it will be seen that the ring A is acted upon at all times by steam pressure from within and without, the steam in the space G tending to expand it, and the steam in the space F tending to contract it. Claims: The arrangement as described.—No. 16152. October 11th, 1890. 6*d*.

ELECTRICITY.

ALTERNATE CURRENT MOTORS.—*L. B. Atkinson, London.*—The inventor's object is to construct an alternating current motor which is self-starting and can run at any speed, independently of the number of alternations per second of the supply current. For this purpose a Gramme or drum armature, the winding of which is continuous, is used, connection being made between a collector of ordinary construction in the usual manner. The brushes of this collector are mounted on a carrier and revolved by a small independent self-starting synchronising motor. Referring to the annexed diagrams, Fig. 1 is that of the main motor armature and collector, Fig. 2 that of the synchronising motor, and Fig. 3 that of the complete connections of the motor. The main armature is surrounded by a four-pole magnetic field A B. The armature is wound continuously and connected to collector C in the ordinary manner. Each pair of the four brushes D of C are connected in parallel. These brushes are revolved by the auxiliary motor at such a speed as to bring the brushes—and thus the polar points—to the position shown at the time of maximum

current. The laminated magnetic field is made up of thin plates of the form shown, the internal poles being surrounded by coils E. In the centre is a laminated armature, having four coils corresponding to the four poles, each alternate coil being wound oppositely, the coils being connected in series, and the ends of the series brought to collecting rings F G, connected by brushes to the supply. On the same shaft is also a four-part commutator, having the opposite sections H I connected, one pair being connected to F and the other to G. On this commutator the brushes press, the ends of which are connected to the magnetising coil E, connected to the main motor. Claims: (1) In an alternating current motor the combination, with a fixed magnetic field, of a continuously wound armature and commutator, having a rotating brush frame and brushes, revolved by a subsidiary self-starting synchronous motor, so as to cause the polar points of the armature to revolve synchronously, independently of the speed of the motor; (2) the combination, with a fixed armature of a continuously wound revolving magnetic field, having a commutator or distributor and coils forming consequent poles, in connection with a rotating brush carrier and brushes, revolved by a subsidiary self-starting synchronous motor, so as to cause the resultant magnetic poles to revolve synchronously, independently of the speed of the motor; (3) in an alternating current motor, the brushes revolving with the commutator in combination with a double wound armature having two circuits connected to alternate commutator sections; (4) the combination and arrangement of parts and connections of an alternating current motor, substantially as described and illustrated.—No. 135. January 3rd, 1890. 8*d*.

MAGNETIC SEPARATOR.—*G. W. Elliott, Heeley, Sheffield.*—The apparatus is for the purpose of separating iron or steel from other materials, and consists of a cylinder of wood or other non-magnetisable material supported between two pairs of rollers, and revolved by means of a suitable driving band passing round it. This cylinder carries, at equal distances apart, four or more electromagnets, the ends of which project through the cylinder and are connected to iron plates fixed to the inside thereof. The circuit through the coils of the electromagnets is supplied by means of a fixed insulated metal ring embracing the cylinder, and against which press four brushes, fixed to the cylinder and connected to the winding on the magnets. This ring is cut away at its upper part, so that, as the magnets pass this part, they are

Digitized by Google

short circuited. The return is formed by means of a metal ring fixed to the cylinder and in connection with the magnets, and a fixed brush pressing thereon. A suitable inclined tray is fixed inside the cylinder, but so that it does not revolve therewith, to receive the iron or steel as it is dropped by the magnets as they become short circuited. The cylinder is also slightly inclined, so that the material, as the cylinder revolves, always tends to travel in one direction. Three claims are made.—No. 1555. January 29th, 1890. 8*d.*

ELECTRICAL DISTRIBUTION.—*F. Van Rysselberghe, Brussels, Belgium.*—The method adopted by the inventor to reduce the electric transport to a minimum is by establishing on a uniform electric canalisation a great number of generators actuated by hydraulic motors supplied from a second canalisation with water at a high pressure. In the accompanying illustrations Fig. 1 is a

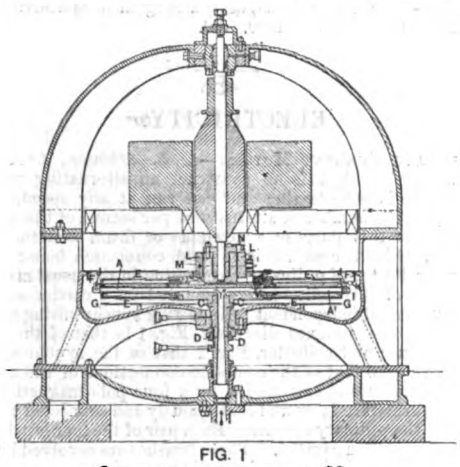


FIG. 1

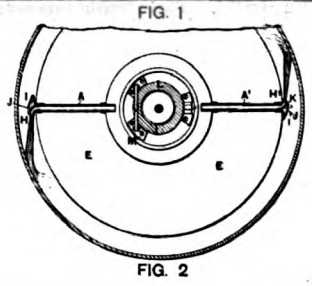

FIG. 2

vertical section, Fig. 2 a horizontal section, and Figs. 3 and 4 details of a combined hydraulic motor and an electric generator arranged according to this invention. The motor comprises two straight tubes A A^1, having at their outer extremities lateral apertures B B^1, through which the water escapes and, striking against the framework, causes the tubes to revolve around their common axis C, through which the water is supplied and which runs in a suitable step bearing D. A cylindrical casing E is arranged around A A^1, and shields F G are arranged as shown (Fig. 1) to prevent undue friction with the waste water. For the purpose of regulating the speed of the dynamo, governors are used, which consist of two obturators (Figs. 3 and 4). These obturators H H^1, arranged at the ends of A A^1, are movable around their respective axes I I^1, and are connected together by a single rod J, a mass K upon the side of which tends, by centrifugal force, to close the obturators, but whose action is partially counteracted by a weight L pivoted to the axle M, and which acts upon J in an opposite direction to K. The movement of L is limited by set screws, and its movement proportionally regulated by a spring N. Claims: (1) A system of hydro-electric distribution, which consists in combining an electric canalisation with a hydraulic canalisation and with hydro-electric generators, the latter being fed by the hydraulic conduit and feeding in their turn the electric conduit; (2) the combination of an electric canalisation of uniform sectional area, with any number of hydro-

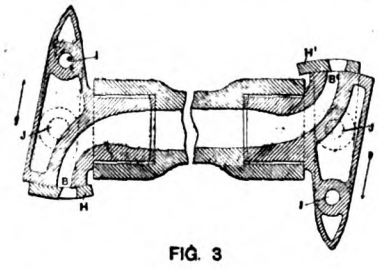

FIG. 3

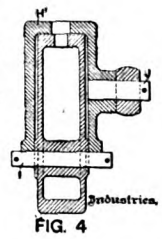

FIG. 4

electric generators; (3) the combination of a high-pressure hydraulic canalisation with an electric canalisation having uniform, but comparatively small sectional areas, and a large number of hydro-electric generators of the type described above, the number of generators to be established varying in accordance with the consumption of electrical energy.—No. 20994. December 31st, 1889. 8*d.*

GALVANIC DRY ELEMENTS.—*C. Smith, London.* (*W. L. F. Hellesen, Copenhagen, Denmark*).—The invention relates to dry manganese elements in which the exciting liquid is mixed with a small percentage of a slimy substance, such as tragasanth slime mixed with plaster of Paris. The dry element consists of two receptacles, one within the other, the interior receptacle being made of zinc and provided with ventilating holes. The space between these two receptacles is filled with sawdust or a similar substance. The carbon used is hollow, covered on the inside with a depolarising substance, its interior being filled with a substance capable of absorbing a large amount of moisture. Outside the depolarising substance is a doughy or similar substance containing the electrolyte. Above this is a porous layer such as plaster of paris covered over with a very close compact layer, such as pitch, so that the escaping gas must pass through the plaster of paris layer, thence through the ventilating holes placed opposite this in the zinc receptacle, and finally pass out through air tubes close to the bottom of the outer receptacle. Claims: The improved galvanic dry element constructed substantially as described.—No. 1306. January 24th, 1890. 6*d.*

ENAMELLING METALS.—*A. E. Robinson, Wolverhampton, & W. H. Wheatley, London.*—The inventors, instead of heating metal plates and other articles to a high temperature in a "muffle," after having thoroughly cleaned same, heat them by a current of electricity from a dynamo or other suitable generator. The article is connected at its opposite ends to suitable clips or terminal pieces which are connected to the two poles of the generator, so that the said articles form the principal resistance in the circuit. The current is regulated to suit the different fusing points of the various enamels employed. Claims: (1) The method of heating plates during the process of enamelling consisting in subjecting them to the action of an electric current which can be regulated according to the temperature required; (2) enamelling metal plates substantially as described.—No. 1894. February 4th, 1890. 6*d.*

TELEPHONIC CIRCUITS.—*E. Gwosdeff & H. Bunge, both of St. Petersburg, Russia.*—The object of the inventors is to prevent any disturbing action in long circuits, so that telephonic communication can be carried on over a greater distance than heretofore. To effect this the inventors connect the line and return wires at both stations by branch conductors in which are introduced resistances (rheostats) or electromagnets, the extent of the resistances being determined by experiment. The same effect is also produced with condensers if such be used in place of the resistances in the branch conductors. The electrical capacity of the condensers must be determined in every case by experiment. Claims: (1) The means for preventing disturbing action in telephonic circuits consisting in the use of branch conductors between the line and return conductor, or generally between the outward and return terminal screws of telephonic circuits, in which branch conductors are introduced either resistances, electromagnets, or condensers; (2) the use, in long telephonic lines, of discharge conductors between line and return wires, in combination with contact closers for automatic intermittent making and breaking of the communication with the discharge conductor.—No. 836. January 16th, 1890. 8*d.*

MINING MACHINERY.—*W. B. Brain & F. Baker, both of St. Kilda, near Melbourne, and A. J. Arnot, Melbourne, Victoria.*—In the annexed illustrations Fig. 1 is a side elevation, and Fig. 2 a horizontal central section on a small scale of a mining

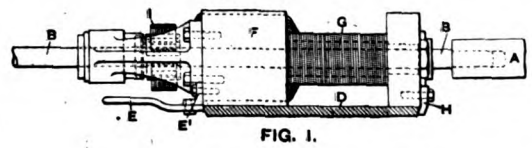

FIG. 1.

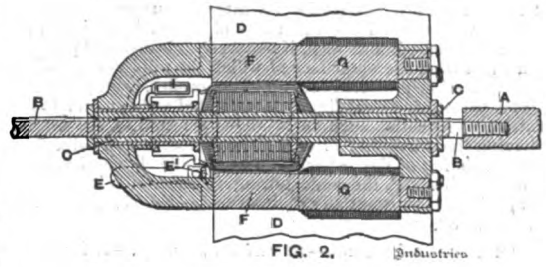

FIG. 2. Industries

machine constructed on the principle of this invention. A is the earth-boring auger fixed to the end of a spindle B sliding in but revolving with the hollow spindle C of an electromotor, as shown. In order that this motor may be moved bodily parallel to the work, it is arranged upon a comparatively long bed-plate D, having bevelled edges in order to admit of the employment of a holding-down clamp E pivoted to the underside of a bracket E^1 secured to the forward ends of the pole-pieces F of the field magnet G. This clamp is adapted to grip the bed-plate against a pair of clamp pieces H at the other end of the field-magnet, the bed-plate being fixed in any suitable manner. The armature and commutator are of the ordinary construction, and are fixed upon the hollow shaft C, the brushes being held in carriers I fixed as shown. Claims: An improved electrical rock drill, coal-digger, or earth cutter consisting essentially in the combination with an earth-boring auger of an electromotor having a hollow spindle such as C, through which the spindle connected to such auger can pass freely longitudinally and at the same time be caused to rotate therewith substantially as and for the purposes herein described and illustrated.—No. 12,997. August 19th, 1890. 6*d.*

ELECTRIC METERS.—*S. Z. de Ferranti, London.*—In meters for recording alternating currents in which an armature or spindle is caused to be rotated by the passage of the current, the inventor magnetically suspends the armature or spindle so as to reduce the friction on its pivots. The suspended magnets used for this purpose are also in some cases used for producing Foucault currents in a metallic disc carried by the spindle to retard the armature's motion. When the spindle is vertical and the armature an iron disc, fixed permanent magnets with their poles in proximity to the upper surface of the disc may be used, or a copper disc may be interposed between the poles of the armature or between the poles and an iron disc on the spindle. Claims: (1) Suspending or partially suspending the armature spindles of electric meters by magnets; (2) an electric meter for recording the passage of alternating currents in which the armature spindle is suspended by an electromagnet or magnets energised by the alternating current; (3) an electric meter in which the armature spindle is suspended by a magnet and in which the suspending magnet serves also to produce Foucault currents in a metallic disc carried by the spindle; (4) the improvements in electric meters substantially as described.—No. 2653. February 18th, 1890 8*d.*

SECONDARY BATTERIES.—*J. K. Pumpelly & F. Butterworth, both of Chicago, Illinois, U.S.A.*—The object of the inventors is to prevent the rapid evaporation and the spilling of the electrolite solution when the batteries are used in a moving vehicle. The positive and negative electrodes, composed of a set of metal plates, preferably perforated, are fixed one above the other in a horizontal position and with a suitable space between them. The space between them is then filled with cellulose packing, and when the cell is thus packed, a sufficient quantity of the electrolytic solution is poured into same, so as to thoroughly saturate the cellulose when the battery is ready for use. Six claims are made, embracing the use of cellulose or woodpulp in secondary batteries to prevent the escape either by evaporation or spilling of the electrolytic solution as described.—No. 16064. October 10th, 1890. 6*d.*

MISCELLANEOUS.

MANUFACTURE OF TUBES.—*C. R. Smith, Providence, Rhode Island, U.S.A.*—The invention relates to the manufacture of seamless tubes. The process consists of drawing up a sheet of metal into the form of a longitudinally split tube or shell in the usual manner. This is then placed upon an arbor, which has adjustable sleeves capable of being fastened in position upon said arbor, the shell being located on the arbor between the sleeves. The tube and arbor are then passed through the flame of blow-pipes, so fusing the metallic shell upon the arbor, so as to flow the edges of the longitudinal opening together. The shell is then drawn through a draw-plate whilst still upon the arbor to give the exterior surface a smooth finish. The sleeves are then removed from the arbor and the tube drawn off. If a metal-plated hollow wire is required one split tube is placed upon the arbor, and is covered with borax or other fluxing material, and a second tube of different metal slid over it, but in such a manner that the longitudinal slot in one tube is opposite a solid part of the other. The two tubes are then fused and drawn as described. Five claims are made, embracing the process as described with modifications.—No. 17249. October 28th, 1890. 8*d.*

NUT LOCKS.—*C. A. Thompson, Irwin, Pennsylvania, U.S.A.*—Formed in the screwed part of the shank of the bolt is a longitudinal slot, and around the nut, which may be of any suitable shape, is a thin metal sleeve, which fits the bolt accurately. Projecting from one end of this sleeve are projections or arms, the ends of which are bent round to embrace the inner face of the nut. The opposite end of the collar projects slightly beyond the outer face of the nut, and a series of spring lips are cut in it which project inwardly towards the bolt shank and engage the longitudinal groove therein, so preventing the nut revolving on the shank in that direction in which it must turn to unscrew itself. Claims: (1) In combination with a bolt having a longitudinal groove therein, a nut and a strap or case encircling the nut, and having a series of spring lips extending therefrom over the face of the nut to engage with the bolt; (2) a bolt having a longitudinal slot, and having a rounded point together with a nut carrying a sleeve as above described; (3) a bolt having a longitudinal slot and a strap or case encircling the nut, and having fingers extending backwards therefrom and passing on to the back of the nut as described.—No. 19422. November 28th, 1890. 6*d.*

ANTI-CORROSIVE BOILER COMPOUND.—*J. L. Wade, London.*—The compound is for the prevention and removal of incrustation in steam generators, and consists of a compound prepared by treating in a boiler or other suitable receiver the following ingredients—viz., caustic potash, esparto grass, and water. These are boiled until the esparto grass is reduced to a pulp, when there is added thereto sumac finely powdered, containing tannic acid. After this addition the mixture is further boiled until the whole is converted into a homogeneous mass. While in this condition the following substances, each in solution, are added:—Potash, chloride of potash, silicate of soda, Irish moss, and lastly, creosote and green mineral oils. The compound is then ready to be added, from time to time, with the water in the steam generator. The quantity of the various ingredients are not stated. Claims: A compound which not only removes and prevents incrustation, but which, by covering the interior of the boiler or tubes with a dark film-like coating, preserves the plates from corrosion, also at the same time neutralising the corrosive properties present in the water.—No. 18451. November 15th, 1890. 4*d.*

NON-CONDUCTOR OF HEAT.—*H. W. Johns, New York, U.S.A.*—The process of manufacturing a non-conducting and sound deadening compound according to this invention is as follows:—Sponge, either picked apart, cut, or shredded, is taken, together with minerals or mineral products, such as agalite, actinalite, chrysolite, hornblende, mineral wool, and the like, or any two or more of them if preferred, in a fibrous condition, and metallic turnings or filings, the oxides of the metals, and chalk, and the whole is then mixed together. The resulting mass after being pressed is ready for use, and may if desired be wetted with any suitable sizing or adhesive substance, such as silicate of soda, rubber solution, starch, glue, and the like, and then pressed into such shapes or forms as desired. Claims: (1) The herein-described composition of matter, consisting essentially of fibrous or comminuted sponge and hornblende, mineral wool, the oxides of the metals, or like bodies, substantially as set forth; (2) a composition consisting of the above-mentioned ingredients, together with an antiseptic or disinfecting material; (3) the combination of fire-proofed sponge, and hornblende, mineral wool, the oxides of the metals, and like bodies; (4) the combination of water-proofed sponge and hornblende, mineral wool, the oxides of the metals, and like bodies.—No. 19202. November 25th, 1890. 4*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.

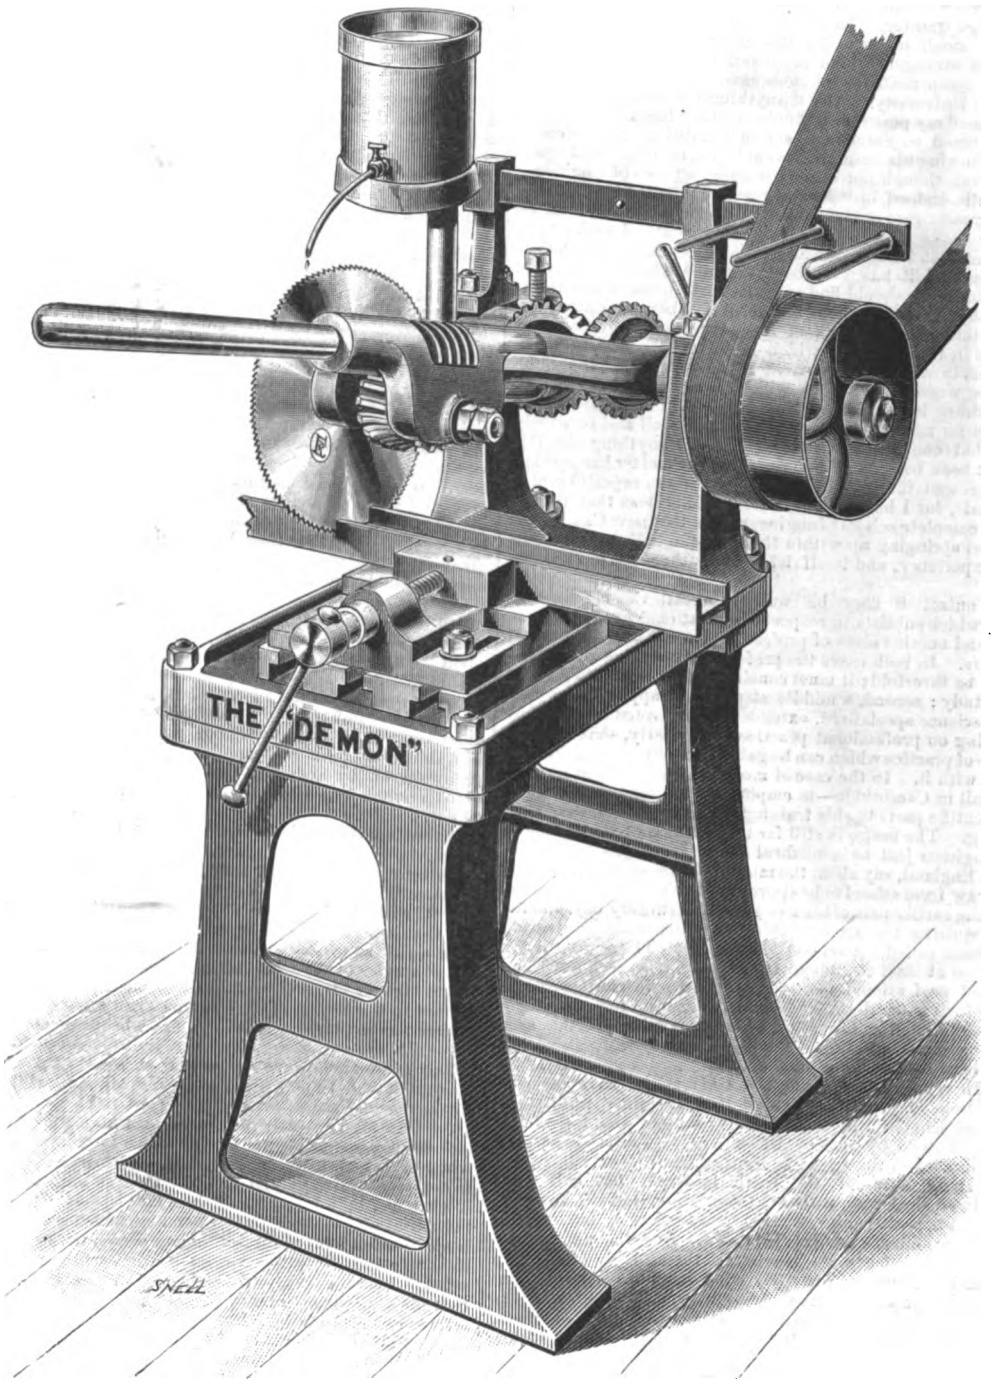
THE "DEMON" COLD IRON SAW.

THE engraving given herewith shows a general view of the "Demon" cold saw, designed for cutting iron, mild steel, or other metals of fairly large sections, that is, up square or round, and any rectangular section up to 8in. by to 4in. 4in. The maker, Mr. R. G. Fiège, of 11, Queen Victoria Street, London, E.C., claims for this appliance that it is a cold iron saw, at once powerful, simple, and effective. It is always in readiness for work, and can be worked by inexperienced workmen. The bed-plate has T slots, to receive a parallel vice, which can be fixed at any angle for angular cutting. The articulated lever carries a saw of 10in. or 12in. diameter, on the spindle of which a bronze pinion is fixed, gearing with the worm shown. The latter derives motion from a pair of bevel wheels, which are in turn actuated from the pulley shown in the engraving. The lever and the saw connected with it can be raised and held up by a pawl while the work is being fixed. In small work the weight of the lever itself is found sufficient to feed the saw, but in heavier work it is found necessary to attach a weight on the end of the lever. The machine is fitted with fast and loose pulleys, strap-fork, and bar. We are informed that one of these machines is capable of making 400 cuts through bars of Bessemer steel 4in. diameter, each cutting occupying six minutes on an average, without changing the saw.



THE "SHARPSHOOTER" CLASS OF TORPEDO GUNBOATS.

BY the recent trials of the first-class torpedo gunboat "Gossamer" at Sheerness, the possibility of a vessel of the "Sharpshooter" type to pass through the prescribed eight hours natural draught trial on the first attempt, without experiencing a breakdown, has at length been fully demonstrated. The repeated failures which have characterised the trials of previous vessels of this kind have caused not only a considerable amount of disappointment to their designers, but have also been a source of much annoyance and anxiety to the constructors of their machinery. The ultimate utility of this class of vessel has frequently been called in question on account of their frailty. In their construction the scantlings have been reduced to the lowest possible limit, and, considering the abnormal horse-power which the machinery was intended to develop in relation to its weight, and the limited space allotted to it, experts have not been slow in regarding a speed of 21 knots and 4,500 i.h.p. as too much to expect from them. Certain it is that the estimated speed and power have not as yet been maintained, nor even approached, in any one of these vessels, and in virtue of the performances of the "Spanker," "Speedwell," and the unfortunate "Sharpshooter," we may feel confident that the highest hopes of their designers will never be realised, at least until some alterations are made either in the hull or machinery of these vessels. The vibration experienced when working with only a moderate allowance of forced draught has already necessitated the addition of a large amount of material to their hulls, in the shape of intercostals and stiffeners in the wake of the engine and boiler spaces, to better enable them to withstand the strains of their powerful machinery. After strengthening the hulls of the "Sheldrake," "Speedwell," "Spanker," and "Skipjack," the officials at Whitehall determined to submit one of them to a series of trials, in order to ascertain what speed and power could be obtained without injury to the boilers. The "Speedwell" was chosen, and, on attempting to maintain 3,500 i.h.p. with an air pressure of 1·5in., the trial had to be abandoned on account of leaky tubes. A subsequent three hours trial was made on the 27th February of last year, when a speed of 17 knots was registered, the engines developing 3,584 i.h.p., with 257 revolutions. Notwithstanding that the contract horse-power for the engines in these vessels was fixed at 4,500, an order was issued previous to the trial of the "Skipjack" in September last, prohibiting the engineers to exceed 3,500 h.p. The realised results, however, with this vessel were—Speed, 19·75 knots, and i.h.p., 3,560. This is about the best performance recorded with any vessel of this type, and is certainly a long way in advance of the average 16·5 knot speed of the "Sharpshooter," which was attained during the regulation eight hours trial in October last, with a mean i.h.p. of 3,010.

Repeated trials with the "Sharpshooter" and "Spanker," built at Devonport, and engined by Messrs. Bellis & Co., of Birmingham, have proved that it is hopeless to expect even 4,000 h.p. without considerable apprehension on the part of the officers in charge of the machinery. Only in October last an alarming incident occurred on board the "Spanker" during a three hours trial under forced draught, when the tubes of the

THE "DEMON" COLD IRON SAW.

CONSTRUCTED BY MR. R. G. FIÈGE, 11, QUEEN VICTORIA STREET, LONDON, E.C.

GENERAL VIEW.

starboard boiler gave out and leaked to such an extent that the boiler was at once well nigh emptied. On this occasion a speed of 19 knots was reached, with the engines developing 3,760 i.h.p., and it was while endeavouring to attain 4,000 i.h.p. that the accident happened, which but for the means adopted, since the "Barracouta" disaster, to prevent the flames and gases from the furnaces issuing into the stokehold, the consequences might have been serious. After every conceivable alteration made by the contractors for the machinery, in regard to the boiler fittings, draught, &c., with the idea of securing the estimated results, had been tried and stamped by failure, the Admiralty sanctioned a reduction in the contract horse-power from 4,500 to 3,500. Notwithstanding this reduction the "Spanker" and "Sharpshooter" were at last taken over from Messrs. Bellis & Co., after having failed to maintain the reduced power on trial for the regulation period.

The estimated horse-power with natural draught for this class is 2,500 during a period of eight hours, and the "Gossamer," built at Sheerness Dockyard, has recently scored a success by exceeding the stipulated power by 117·8, the average recorded during the eight hours being 2,617·8. The "Gossamer" is the first warship the machinery of which has been constructed at Sheerness, and is also the first of her class engined by the Admiralty. From the first turn of her engines in the preliminary basin trials to the completion of her eight hours trial not the slightest hitch or difficulty has been experienced with the machinery of this vessel, a performance which is quite unique in the records of her class. The Admiralty have expressed their satisfaction with the results of the natural draught trial of the "Gossamer," but have issued an order that she is not to be subjected to the ordeal of a forced draught trial. She is to be commissioned forthwith, and will be the first of the seventy-two vessels provided for under the Naval Defence Act to leave the Royal dockyards. According to this Act, twenty-seven first-class torpedo gunboats are to be completed before the 1st April, 1894. Of this number, nine have already been built—viz., the "Sharpshooter," "Speedwell," "Salamander," "Spanker," "Seagull," "Sheldrake," "Skipjack," "Gossamer," and "Gleaner." They are popularly known as torpedo-boat catchers, and their official speed is tabulated as 21 knots, but, so far, not one of them, in all their numerous trials, have yet been able to maintain an average speed exceeding 19·75 knots for the official full period of time. First-class torpedo boats have already realised 6 knots in excess of this speed in trial, and have maintained a 20-knot speed for a lengthened period. Under these conditions, then, it is hardly likely that recent first-class torpedo boats will be taken in the chase by these so-called "torpedo-boat catchers."

THE UNIVERSITY TRAINING OF ENGINEERS.*

THE feelings of pride, of responsibility, and, above all, of diffidence natural to a young man who finds himself at the goal of professorial ambition—a Cambridge Chair—would surely be sufficiently overwhelming even to one who had all the advantages of a Cambridge training. In my case these feelings are accentuated in no small measure by the consciousness that I come among you a stranger, whom not even the kindness of your welcome can compensate for his ignorance of the traditions and usages of the University. And if anything could make me still more sensible of my position, it would be the reflection that I am called to succeed so eminent a son of Cambridge as Professor Stuart. Following his example, I would wish to regard this chair as being in fact, though not strictly in name, a Chair of Engineering. The title, indeed, of "Mechanism and Applied Mechanics" covers the greater part of the subject of engineering, in so far as that subject lends itself to academic treatment. I understand there has been some discussion as to the proper scope of such a professorship, and it has even been disputed whether a department of engineering should find any place within the University. In view of that, it may perhaps be useful if I beg your attention for a short time while I speak of the education of engineers, of the function in their training which a university may fulfil, of the directions in which development of the department should be sought; in a word, of the aims which I venture to cherish in taking up these high and arduous duties. The education of engineers is no new subject: it has been so well and so widely discussed that one can scarcely hope to say anything about it that has not been better said before. But the matter has perhaps enough of present interest for us to excuse the repetition of a twice-told tale, for I have to plead for nothing less than the inclusion of a complete school of engineering in that new Cambridge which is fast springing up within the old—the heir to its traditions and experience, and itself rich in the enthusiasm of vigorous youth.

At the outset it may be well to recall the close correspondence which subsists in respect of educational needs between engineers and another class of professional men—namely, medical practitioners. In both cases the professional training to be complete must be threefold; it must consist in, first, a basis of general scientific study; second, a middle structure of applied science—that is, of science specialised, extended, and adapted with a view to its bearing on professional practice; and lastly, that kind of knowledge of practice which can be gained only by coming directly in contact with it. In the case of medicine, there is now no need—least of all in Cambridge—to emphasise the importance of the earlier scientific parts of this training. But it is otherwise with engineering. The usage is still far too common of attempting to train an engineer just as a medical practitioner was commonly trained in England, say about the middle of this century, when he was sent raw from school to be apprenticed to a doctor in practice, spending the earlier part of his five years as a surgery boy, and the later in acquiring the art of talking to patients and cultivating what has been called a good bedside manner. The apprentice in medicine had at least the advantage of close association with an experienced professional man, the apprentice in engineering is seldom so fortunate. I am far from undervaluing the advantage, or of questioning the necessity, of contact with practice as a part of professional training. But the tendency in England has certainly been to ignore the fact that this is not all that is required. In regard to medicine the Universities have asserted their function, they have recovered their historical position as professional schools. No one will now contend that a doctor is adequately trained by passing through an apprenticeship which takes no account of the scientific basis of his subject. In regard to engineering, however, the battle is as yet but half won. Experts have declared, with one voice, not, indeed, that the system of apprenticeship should be abandoned, but that it should be modified and supplemented. And the universities and provincial colleges are bestirring themselves, often with very remarkable energy, to supply what has been lacking. But the youth who aspires to the profession, or the parent who has sons to settle in life and wants to make engineers of them, often finds himself at a loss. In too many cases he asks and takes the advice of old engineering friends, once trained as apprentices themselves, and now perhaps not very conversant with the scientific movement of their profession, and the result is that the youth is sent directly from school into the office of a civil engineer or into a great mechanical workshop. His powers of observing and reasoning are little developed: he has no grasp of mechanical principles: his stock of mathematics is scanty at the best, and he is absolutely ignorant of how it may be applied to material affairs. The theory of engineering is a sealed book to him, and in the office or the workshop he finds no one who will break the seal. Even as to matters of practical detail he is left pretty much to pick up what he can: it is the business of nobody to teach him. In time, of course, if he is a man of the right sort he does learn a good deal, and some of the lessons are lessons that could be learnt in no other school. Before his five years or so of apprenticeship have expired he has seen actual work in all its stages. He has learnt something of the commercial conditions under which it is done. He has become heir to the experience of an earlier generation of engineers. He has found that to make himself useful is the first step to success. He has been in touch with men; he has learnt their habits and how they are to be managed. He has become acquainted with matters of organisation and business routine. He has come to know what good work is, and what it costs, and what is the time that should be taken for one and another kind of job. These lessons are invaluable, but I submit they are not the whole of engineering. If the pupil, on quitting his apprenticeship, carries away the faintest idea of how scientific principles bear upon engineering practice, he is exceptionally fortunate. The apprenticeship makes no provision whatever for teaching him that. Lest you suspect me of painting too black a picture, listen to a criticism passed on the system of engineering pupilage by an eminent practical engineer. In the evidence laid before the Royal Commission on Technical Education, whose report was issued in 1884, Dr. Anderson, now director of the Woolwich Ordnance Factories, speaking then as a partner in the Erith Ironworks, said:—

"I have from twelve to twenty pupils who come chiefly from the great public schools. . . . . The minds of most of these young men who come to serve their apprenticeship with us are a complete blank as regards any of the sciences. . . . . Their mathematical knowledge is generally of a useless kind: it is all pure mathematics, and they do not know how to apply it. They might just as well know no mathematics at all. They do not seem able to apply their knowledge to the simplest practical questions. . . . . I have an uneasy feeling that the pupils who leave our establishment know little or nothing except the use of their hands."

That is the verdict of a practical man who has studied the system under his own eye, in his own works. It is perhaps more severe than anything a professor of engineering could well venture to say. Dr. Anderson's evidence is so representative of what I conceive to be the drift of the best modern opinion on this subject, that I will quote a few sentences more. Dr. Anderson is not merely a destructive critic, he is prepared to point out a remedy, and the remedy he advocates is exactly that which I wish to press upon your notice. Asked what was his ideal of the training of the higher class of mechanical engineers—viz., employers and managers—in the future, he replied: "They ought to have a training such as the scientific colleges can give, and then come and carry out a shorter apprenticeship in the works. Instead of remaining five years at the works, as they do now in a great many cases, it would be better for them to spend three years at college, and then come for two years to a practical training. . . . . I am convinced that that would be better." And Dr. Anderson then goes on to speak in appreciative terms of the kind of training in the theory of engineering which is now offered in many British colleges, advocating it as a much-needed preliminary stage in the training of an engineer. It gives him something that the apprenticeship does not give, and at the same time allows the apprenticeship to be abbreviated without loss, by preparing the pupil to reap its advantages in a much shorter time than he would otherwise require. Much other evidence was laid before the Commission to the same effect—notably by Professor Kennedy, who could speak with the double authority of a successful practitioner and an experienced teacher of engineering. These, I take it, are beyond question the lines along which we should proceed: not to supplant the apprenticeship but to supplement and shorten it. These are, in fact, the lines—already marked by much substantial progress—along which the advance has been made by the Scottish Universities and many of the higher English colleges. The chief aim of a University School of Engineering is to give such a training in pure and applied science that when the pupil follows it up by spending two or three years in contact with actual constructive work he is well fitted to begin his professional career.

Before speaking of the work of the English schools in any detail, however, let us glance at what has been done abroad. Nothing could be sharper than the contrast which presents itself between the routine of pupilage in England, as we still often find it, with absolutely no place for theoretical instruction, and the Continental method, in which theoretical training plays so large a part as to leave little or no room for practice. The origin and character of the Continental schools in which the education of the highest class of engineers is accomplished are well described in the Report of the Commissioners, from which I quote a few sentences (Report, p. 507):—"The beginnings of the modern industrial system are due in the main to Great Britain. Before factories founded on the inventions of Watt, of Arkwright, and Crompton had time to take root abroad, and whilst our own commerce and manufactures increased from year to year, the great wars of the early part of this century absorbed the energies and dissipated the capital of Continental Europe. . . . . Thus when, less than half a century ago, Continental countries began to construct railways and to erect modern mills and mechanical workshops, they found themselves face to face with a full-grown industrial organisation in this country, which was almost a sealed book to those who could not obtain access to our factories. To meet this state of things foreign countries established technical schools like the Ecole Centrale of Paris and the Polytechnic Schools of Germany and Switzerland. . . . . With the exception of the Ecole Centrale, all these schools have been created and are maintained almost entirely at the expense of the several States, the fees of the students being so low as to constitute only a very small proportion of the total income. The buildings are palatial, the laboratories and museums are costly and extensive, and the staff of professors is so numerous as to admit of the utmost subdivision of the subjects taught."

To this class belong the Federal Polytechnic School of Zürich, which has so high a reputation as to draw some 70 per cent. of its students from outside of Switzerland, and the Polytechnics of Munich, Vienna, Stuttgart, Dresden, Hanover, Carlsruhe, Aix, Delft, and Moscow, and the technical high school of Berlin. The schools I have named represent a capital expenditure of not less than three millions sterling, and are maintained at an annual charge of over £200,000. They exhibit, as might be expected, somewhat wide differences in regard to their curricula of studies. But they have this general intention in common, that they aim at teaching not merely the scientific principles that underlie the art of engineering, nor merely the relation of those principles to the art—they aim at teaching the art itself. By means of descriptive lectures, and by accustoming the student to design machines and structures, they aim at giving that kind of knowledge of the details of professional practice which we look to the apprenticeship to give. The Moscow school, which, however, is rather exceptional in this respect, affords its students opportunities of mechanical engineering with workshop practice on a comparatively large scale. It includes an engineering establishment, which executes work commercially to the value of £8,000 or £10,000 a year, and in which the foundry alone is big enough to require the employment of 25 workmen. But even with or without such an adjunct as this, the Continental polytechnic school stands in this relation to the training of engineers, that when a pupil has passed through it he is able to earn his bread. He is regarded, at least by himself, as fit for a responsible professional position or for engaging in the design of constructive work. Abroad, pupils go to those schools for just the same reason as, at home, they enter on an apprenticeship. It is the recognised avenue to practice: the diploma of the polytechnic school is the accepted passport to a professional career. Before admission they have usually to pass a somewhat exacting examination in mathematics, mechanics, and physics; in the school itself they carry the study of these subjects to a height which not one in a hundred of English engineers ever reaches. They listen to descriptive lectures from one professor after another, each well versed in the details of some branch of engineering practice. They are given a mass of facts, informing, I think, rather than educative, and finally they are set to make designs which are acknowledged even by unfriendly critics of the system to be an astonishingly clever imitation of real work. There is much that is admirable in the foreign technical schools, and it will be admitted that they have fostered industrial development in France and Germany and Switzerland as perhaps nothing else could have done. But when we examine the constructive work that is carried out in those countries, or when we read the expressed opinions of men who have had experience of the system, we find evidence that the highly finished product of the foreign technical school lacks something that is often present in his rough-hewn English competitor. The Report of the Technical Educational Commission contains emphatic testimony on this point. Even those witnesses who are most alive to the inadequacy of our English apprenticeship as the sole means of training engineers give no encouragement to the idea that we should seek a remedy by copying the foreign polytechnic school. Take for instance the evidence of the late Sir William Siemens, a man rarely qualified to form a sound judgment by his wide knowledge alike of the theory and the practice of engineering, and by his cosmopolitan sympathies. Asked whether he would recommend us to copy the German Polytechnic School, he replied, "Certainly not. . . . . I would rather employ a person who had been brought up in practice and who had supplemented his knowledge by study for himself, than I would take a young man who had been entirely educated at an establishment like one of the polytechnic schools. . . . . I think those schools are apt to teach the student details which he mistakes afterwards for principles."

It would take too long to quote the expressions in which Sir William Siemens amplified and enforced this highly suggestive criticism. Like other authorities, he urges the need of a university training—for the higher class of engineers—to supplement the experience of the workshop, and he agrees that when so supplemented two or three years of workshop practice should suffice. He contends that this training in theory should be given in a university rather than in a special or polytechnic school. He gives hearty approval to the growth of universal teaching in engineering as it has been going on in England, of which I shall presently speak, saying that further development on the same lines is what we need. And as to the character of the teaching that should be offered, the burden of his often repeated advice may be gathered from the sentence I have quoted. It should deal very much with principles and very little with details.

In America we find a number of highly organised and admirably conducted engineering schools, forming in some cases an integral part of universities; in others standing alone. In some respects they follow the Continental pattern, but with a difference. If I were to select one for special reference it would be the Massachusetts Institute of Technology, where the subject of engineering engages the attention of seven professors, with many assistants, and where separate systematic courses of the most thorough kind, each extending over four years, are offered in (1) civil engineering, (2) mechanical engineering, (3) mining engineering, (4) chemical engineering, (5) electrical engineering, (6) sanitary engineering, and (7) architecture. Workshop instruction is given "as an adjunct to the theoretical treatment of professional subjects;" and there is a superbly equipped engineering laboratory for which new rooms, covering 15,000 square feet, were provided less than a year ago. The work of this school is spoken of in the highest terms, and the fact that it has now 900 students bears witness to the estimation in which it is held in the United States. The Massachusetts Institute carries the college training of engineers to a degree of elaboration which we are perhaps disposed to deprecate; but it seems to me to avoid the most serious fault in the Continental schools. Its engineering course, says its President, General Walker, "is designed to thoroughly train the students in the principles upon which the profession is based, and to qualify them to occupy technical positions of trust and responsibility as soon as they shall have gained the necessary familiarity with the practical details of the particular branch of the subject into which circumstances may throw them. The principal point which is kept in mind in the course is that principles and practice must go together, and that the student must be made to clearly see the relation between the abstract principles which he learns and the actual everyday work of the engineer, without, however, devoting much time to minor details of practice which he will learn much better and more quickly after he leaves the school."

I turn now to our own country. The university training of engineers as we understand it—the training which it should be our effort to give here—may be said to have had its foundation laid when Rankine was appointed to the Professorship of Civil Engineering and Mechanics in the University of Glasgow. His introductory address—a noble vindication of the harmony of theory and practice in mechanics—was delivered just thirty-five years ago. It will be found printed as an introduction to his text-book of Applied Mechanics, the first of that great series of treatises in which he formulated the theory of engineering with so much of comprehensiveness, of precision, and of philosophic grasp that they hold their place to this day as the most indispensable volumes in the library of the educated engineer. Edinburgh followed twelve years later with the institution of its University Chair of Engineering, of which Fleeming Jenkin was the first occupant. It was my privilege to receive my first lessons in applied mechanics from that most inspiring and sagacious teacher, who succeeded in bringing his subject into close touch with the co-related sciences in the universal curriculum and in securing academic recognition of the course by means of the degree of Bachelor of Science in the Department of Engineering. The work so well begun in Glasgow and in Edinburgh goes on, but for the moment the development of these engineering schools has been outstripped—in respect of material equipment—by that of some of the younger colleges, which have had the advantage of a greater command of resources. If we wish to see the modern British ideal of a university school of engineering most fully realised we must rather turn to Manchester, where the genius of Osborne Reynolds, aided as it has been by the wise liberality of the Whitworth Trustees in spending

* Abstract of an introductory lecture delivered at Cambridge on the 29th ult. by Professor J. A. Ewing, F.R.S.

Digitized by Google

£10,000 upon an engineering laboratory, has achieved results of which Owens College is justly proud. The Victoria University is indeed peculiarly rich in Engineering Schools, for besides Owens it includes the Yorkshire College in Leeds and University College in Liverpool, each admirably furnished for the teaching of engineering. At Leeds the engineers of the district have given unequivocal evidence of their faith in the professional value of a college training by subscribing £10,000 to provide buildings and plant for the department of engineering, and at Liverpool the Walker Engineering Laboratories, recently completed at a cost of some £23,000, form the most lavish provision of which any English college can boast. Time would fail me to speak of the many other institutions in this country at which similar teaching is given, with the aid of more or less perfect laboratory appliances —of the colleges at Birmingham, Bristol, Sheffield, Nottingham, and Cardiff; of the comparatively venerable school of engineering at King's College, London; of such special colleges as that at Cooper's Hill; of the laboratory I have just left at University College, Dundee—in the furnishing of which, again, the local engineers gave substantial help; of the great work the City Guilds have done in London by founding the Central Institution in the West, with Professor Unwin's splendid laboratory, and the Finsbury College in the East, where the suggestive ideas of a most original teacher—Professor Perry—have taken practical shape. Amongst the London schools there is still one that calls for very special mention: I mean University College, for it was there that Professor Kennedy created the first of those laboratories which now fill so large a place in the university training of engineers.

(To be continued.)

APPARATUS FOR DRYING CLAY AND MINERAL EARTHS.

In all branches of manufacture economy is now essential, and an important factor is fuel economy. In order to effect this latter result in connection with the drying of clays, fuller's earth, umber, ochre, barytes, &c., Mr. James Bell, Lower Blowing House, St. Austell, Cornwall, has brought out a new apparatus, which is illustrated below in Figs. 1 and 2. The principle upon which it is constructed is based on the fact that a current of hot air is a good drying agent. A fierce heat applied locally to a slow conducting substance quickly burns it, but if the heat is applied to air in motion, and means provided for its escape, burning is prevented.

One of the great difficulties in existing modes of drying such substances as have been enumerated above is that they get burnt. In Mr. Bell's system a drying floor D is constructed of porous concrete, laid upon T irons so as to allow of 2 cubic feet of air per minute passing

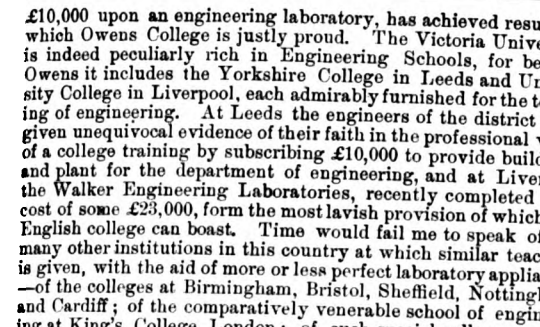

Fig. 1.—Sectional Elevation.

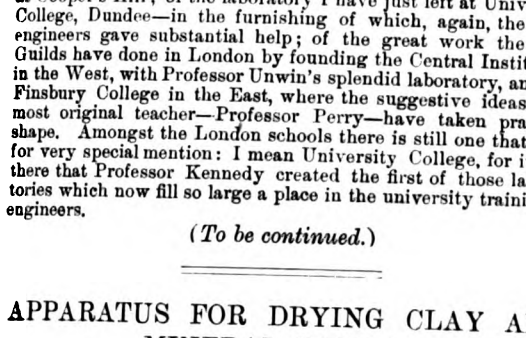

Fig. 2.—Sectional Plan.

through a superficial foot of the floor when the pressure in the air chamber A is ½lb. per square inch. The heat is maintained and increased by means of a wrought-iron flue F, having a fire-place at the end P. This flue extends the whole length of the "dryer." Air is forced into the air chamber through the tube T by means of an air compressor, and, finding no means of escape except through the porous floor, it has to pass through this floor, and the substance to be dried, which is placed upon it. The air in its passage to the chamber is heated by any convenient means—say by exhaust steam—and is further heated by the furnace mentioned. The steam from the material being dried escapes by the pipe E. A dryer has been erected by Mr. Bell, at St. Austell, of this design, and he finds that a heat of 150° to 200° F. forced equally through the material dries it in less than half the time required by a heat of 800° or 900° allowed to take its own time to permeate first the drying floor and then the material to be dried. The dried material can be kept dry in an adjacent chamber. As shown in our illustrations, a chimney can be employed to create a draught, but in the case of the dryer which has been erected Mr. Bell has an air exhauster instead, a water-wheel driving this and the air compressor.

THE "UNIVERSAL" SHEET METAL CUTTING MACHINE.

In the acco mpanying illustrations is shown a machine recently designed for rapidly cutting tinned iron and other metals without the use of special tools, dies, or patterns, which is being manufactured by Messrs. Greenlee Brothers & Co., Chicago, U.S.A. This machine is said to be the outcome of long study and experiment by a practical metal worker. It is claimed for it that it is simple in construction, economical, and capable of doing more and better work in one hour than a man in the ordinary way can do in ten. The makers state that the work turned out by this machine requires no additional trimming. Referring to our illustrations, for which we are indebted to our American contemporary *The Iron Age*, Fig. 1 shows the machine set for cutting the sides of coned and other shaped vessels, and Fig. 2 shows the machine complete, with elbow cutting attachment. The machine has a heavy iron framework, on the top of which slide two head blocks, each carrying two circular cutters. These blocks may be readily moved and locked at any point, and their position is indicated by pointers on the graduated scale shown. The cutters have concave surfaces, and require no grinding or sharpening; they are also adjustable lengthwise on their spindles. The pattern table is supported and slides on a frame which travels on steel guides parallel with the framework. It also swings on a pivot, and can be readily set and locked in any desired position. The elbow cutting attachment includes extension table with support and a large head block with one pair of cutters. Guides or forms (see Fig. 2) for cutting elbows from 2in. diameter upwards can also be furnished.

THE "UNIVERSAL" SHEET METAL CUTTING MACHINE.

OVERHEAD STEAM TRAVELLING CRANE.

CONSTRUCTED BY MR. THOMAS SMITH, STEAM CRANE WORKS, RODLEY, NEAR LEEDS.

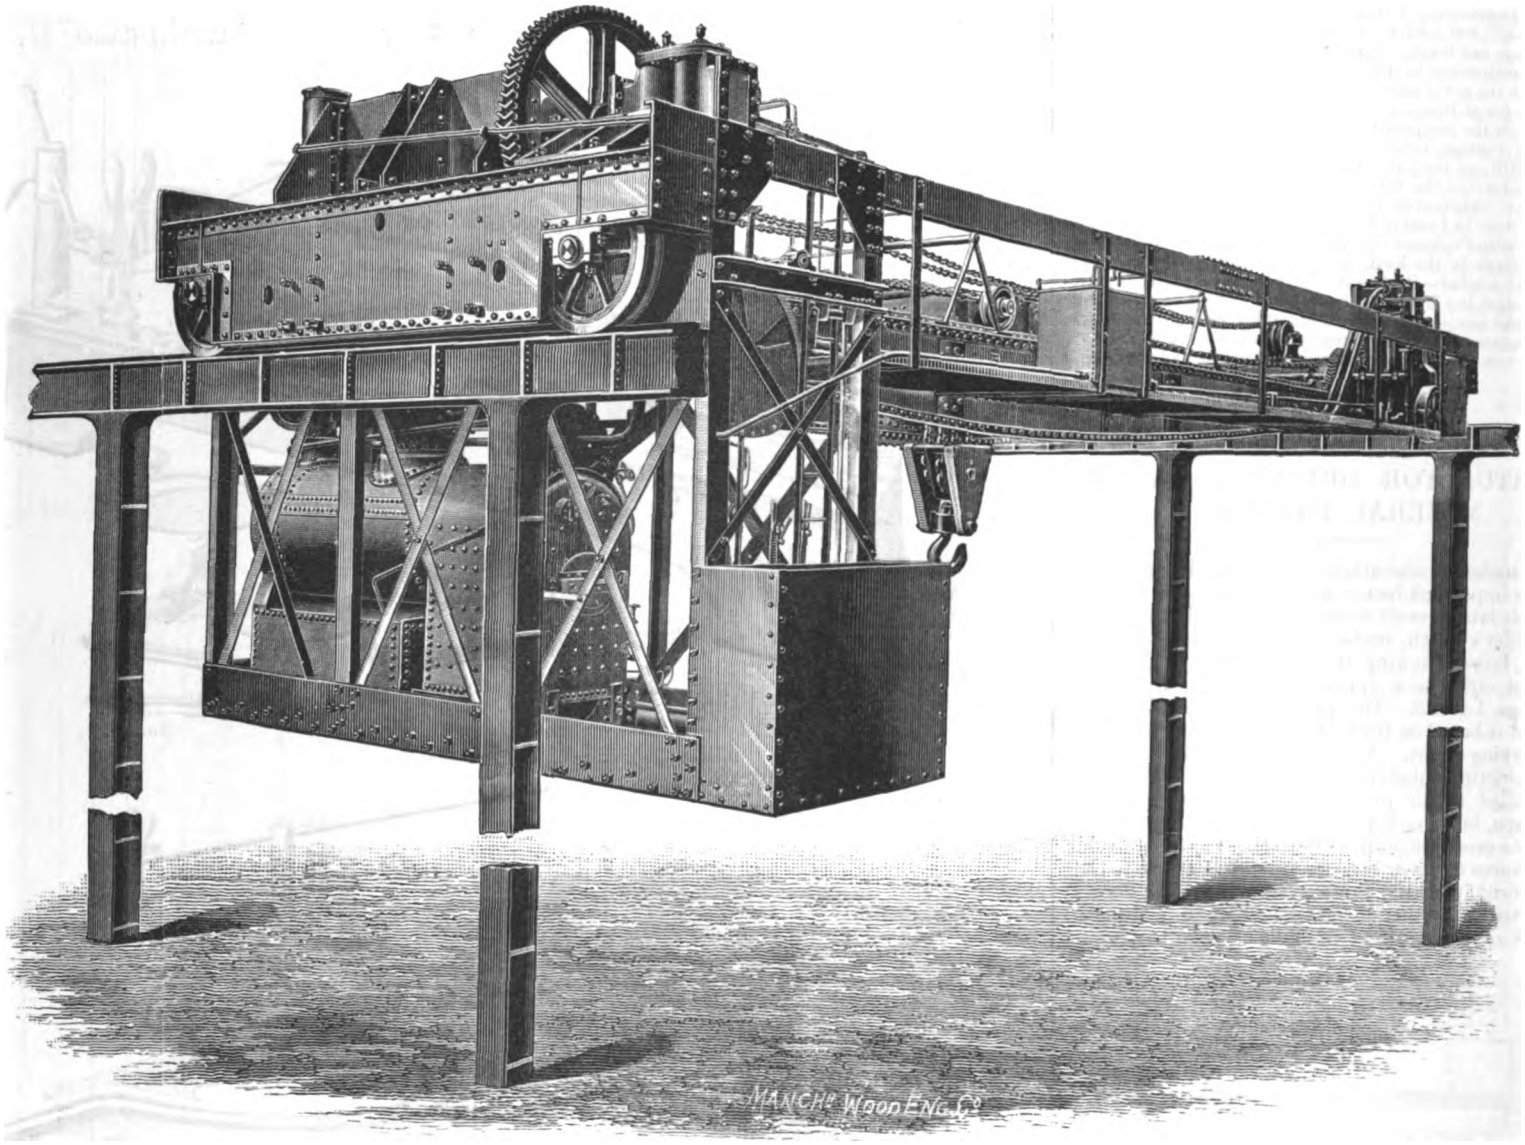

FIG. 1.—GENERAL VIEW.

an interesting paper was read by Mr. R. Pawley, on "A Few Examples of Underpinning," of which the following is a short abstract:—

"Underpinning" was defined as the process of constructing a new foundation to an existing building or structure, and is resorted to in cases where the original foundations of the structure have been inadequate to support the superincumbent weight, in consequence of faulty design in the first instance, or to a subsequent increase in the height and weight of the building; but the necessity for underpinning arises more frequently from the ground in the vicinity of a building being disturbed by the construction of railways, subways, sewers, or similar works at a lower level than the foundations of the adjacent structures. The usual method of underpinning is by excavating in short lengths under the old foundations, and when the required depth is reached, filling the trenches with concrete or brickwork to the level of the old work. The author described the method adopted when the operations had to be conducted in a sub-soil of a wet and silty nature, and also enumerated the various difficulties which had to be overcome in constructing railways in towns where the value of property is considerable, and where the companies would be liable to heavy compensation claims in the event of important buildings being injuriously affected. The following examples of underpinning, which had come within the personal knowledge of the author, were described, the special features of the undertakings being clearly illustrated by diagrams:—(1) The construction of the Hindley and Pendleton Railway under the "Maypole" Hotel, Pendleton, near Manchester. (2) The enlargement of the "Sough" Tunnel, near Blackburn, by lowering the rail level and underpinning the side walls. (3) The construction of the East London Railway under the sugar warehouses at the London Docks. (4) The construction of the East London Railway under the viaduct of the London and Blackwall Railway. A discussion followed the reading of the paper.

At the next meeting a paper on "Air Vessels" will be contributed by Mr. J. Brackenbury.

OVERHEAD STEAM TRAVELLING CRANE.

We show in Fig. 1 above a general view, and in Figs. 2 and 3 on the next page, a side elevation and plan of an overhead steam travelling crane, which has been constructed by Mr. Thomas Smith, of Rodley, near Leeds, for use in a steel works, to lift, lower, and travel with loads up to 15 tons. The crane is designed for hoisting and lowering while travelling transversely or longitudinally, and all the movements are readily controlled from the cage, which is placed at one end of and underneath the transverse beams, and from which the load can be readily seen. All the gear wheels are of steel and have double helical teeth; the shafts are also of steel, and the principal bearings are adjustable and bushed with hard gunmetal. This crane has a separate pair of engines for each motion, which are supplied with steam by the multitubular boiler placed in the cage as shown. The hoisting motions consist of double-purchase gearing, with grooved drum, treble-best iron chain with block and hook, driven by one pair of 8in. by 12in. engines. The transverse travelling motion consists of gearing, chain, and carriage on four tram wheels, with grooved chain pulleys, driven by the second pair of 6in. by 10in. engines, and the longitudinal travelling motion driven by the other pair of 8in. by 12in. engines. The transverse beams are wrought-iron riveted box girders, firmly secured to the end carriages, which are mounted on four double-flanged steel-tyred wheels, set to suit a 38ft. span.

EXHIBITION AT PALERMO.

THERE is to be held at Palermo from 1st November next until the 31st May, 1892, a National Exhibition, in connection with which will be an international section for engines, machines, and tools adapted for small industries. By "engines adapted for small industries" is meant engines that do not exceed 5 h.p. effective, which fulfil the conditions of perfect safety when introduced into small workshops or the rooms of dwelling-houses, and which do not require special and costly erection. "Small machines" denotes machines worked by hand or by engines which would be suitable for industries carried on in small shops or in rooms. The engines will include gas and oil engines, hot air and compressed air engines, hydraulic engines and electromotors. Steam engines will be excluded unless they offer special advantages—namely, great safety, economical working, and simplicity. Those machines and tools only will be admitted which strictly belong to small industries in so far as they assist manual labour, and present the following advantages—viz., lightness, adaptability to various uses, simplicity, possibility of being fixed in any part of a dwelling-house or small workshop, and at such low cost as to bring them within the reach of small artisans. Arrangements are being made for special rates of freight on goods sent for exhibition, and no duty will be charged for articles re-exported. The National Exhibition consists of the following sections:—1, mining and metallurgical products and raw materials; 2, machinery and engineering; 3, chemicals and dyes; 4, food stuffs; 5, pottery and glass; 6, paper, lithography, &c.; 7, textiles; 8, furniture, &c.; 9, liberal arts; 10, naval exhibits; 11, technical education, provident and co-operative societies; and 12, fine arts. Full particulars can be obtained from the Italian Chamber of Commerce, St. Mary Axe, London, E.C.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 17th February, 1891.

Iron.—There are evident signs in the iron market that the worst of the slack season is over, though as yet there is no marked improvement in prices. This may be accounted for by the accumulation of stocks, which will have to be disposed of before a rise in prices can take place. The demand is much more active this week, and there is every reason to expect a fair rise in quotations at an early date. The prices fixed by the Paris Syndicate remain at 128s. 6d. for bars and 136s. 6d. for joists per ton, but very many transactions have been negotiated at 124s. 6d. and 132s. 6d. for bars and joists respectively. On account of the reduction in the tariffs of third-class railway fares on the principal lines, there is every reason to look for an influx of orders for third-class carriages; in fact, the Orleans Railway Company have taken the initiative in asking for tenders for the construction of one hundred of these carriages, and the other companies will also have to augment their rolling stock. There is already a revival in orders for the building trade, and authorisations to construct are being largely demanded from the municipality. The reports from the provinces are hopeful, though as yet there is no important improvement in trade. In the North and the Ardennes endeavours are being made to sell off accumulated stocks at any price. In the latter district the Revin strike is playing havoc with the prospects of trade, and, if not soon terminated, years will be required to make good the injury caused to the industry. In the Haute-Marne district business is fairly brisk, although the orders forthcoming are not of great importance. The steel works of the North and East of France have secured orders for 3,000 tons of rails for Brazil.

Coal.—The coal market still continues very firm, but there is no doubt that when the demand, caused by the exhaustion of stocks consequent upon the long duration of the late frosts, becomes less urgent, there will be a fall in prices.

Copper, Tin, Lead, and Zinc.—Prices for all brands of copper remain unchanged, and the market is slightly weaker than it was. Tins are firmer at the same quotations as last week. The lead market is weak, as is also the zinc, Silesian having fallen 4s. a ton.

Electric Lighting.—At the close of the past year there were in public streets in Paris 297 arc lamps and 115 glow lamps. The following are the official returns of the various installations:—Place du Carrousel, Edison dynamos, 16 arcs of 75 to 100 carcels, price per carcel hour in francs 0·00592 to 0·0044; Parc Monceau, Jablochkoff lamps, 12 arc lamps of 40 carcels, price 0·01184; Parc des Buttes-Chaumont, Brush and Henrion dynamos, 50 arc lamps of 80 carcels, price 0·00375, 30 glow lamps of 1 carcel, price 0·025; Palais Royal, Edison dynamos, 85 glow lamps of 1·6 carcel, price 0·0166; Boulevards, Thomson-Houston and Gramme dynamos, 47 arc lamps of 75 to 100 carcels, price 0·006 to 0·0045—Edison dynamos, 45 arc lamps of 75 to 100 carcels, price 0·0066 to 0·005—Desroziers dynamos, 39 lamps of 75 to 100 carcels, price 0·006 to 0·0045; St. Lazaire Station, Société Alsacienne dynamos, 6 arc lamps of 150 carcels, price 0·00466; Jemmapes and Valmy Quays, Desroziers dynamos, 66 arc lamps of 75 to 100 carcels, price 0·00533 to 0·004; and Avenue de Clichy, Société Alsacienne dynamos, 16 arc lamps of 75 to 100 carcels, price 0·00533 to 0·004fr.

BERLIN, 16th February, 1891.

The Berlin Sea Canal.—This canal, about which much has been said recently, appears to be making progress. It is stated that at present not only is a company in course of formation to construct a canal from Berlin to Hamburg, but that at the same time several capitalists have promised to provide the necessary funds for the preliminary works of the Berlin-Stettin Canal. In the interests of Berlin, *Kuhlow's* states that it is to be hoped that both enterprises will make speedy progress.

Coal Mining in Prussia in 1890.—According to preliminary investigations the coal raised in Prussia has increased from 61·43 million tons in 1889 to 64·48 million tons in 1890. Divided among the five districts of the Upper Mine Office, the output is as follows:—Breslau, 20·09 million tons (19·00 millions); Dortmund, 35·37 million tons (33·85 millions); Bonn, 8·18 million tons (7·08 millions); Klausthal, 0·63 million tons (0·57 millions). In Halle the output of coal is inconsiderable, but on that district falls almost the entire raising of lignite in Prussia, whereas the entire produce of lignite amounted to 15·51 million tons (14·23 millions). In the coal mines there were, on the annual average, 233,143 people employed (212,056); in the lignite mines, 26,309 (24,503). The figures in parentheses refer to the year 1889.

Electrical Exhibition at Frankfort.—The town commissioners have decided to contribute 1,500 marks to the expenses of the proposed International Electrical Congress. The Chamber of Commerce has also voted 1,500 marks for the same purpose. The Electrical Association is also taking important measures for the furtherance of the scheme.

Electrical Street Railways in Berlin.—The magistracy of Berlin has recently passed an important resolution which affects the erection of electrical railways in the streets of Berlin. No concessions are to be granted for street railways which either are supported on columns (elevated railways) or when on the level of the street require supports to be erected in the roads or footpaths.

VIENNA, 16th February, 1891.

The Iron Market.—During the past few weeks the Austrian and German iron works have competed against each other in reducing prices. The renewal of the agreement which was concluded between the Austrian Iron Syndicate and the German Union of Rolling Mills in Berlin, so as to exclude competition in what are termed the natural trade districts, has led to difficulties. The Austrian Syndicate last year, soon after its renewal for three years had been effected, invited the German Union to prolong the existing agreement for the same period of time. The German Union replied that it was prepared to renew the agreement "for a further period." This offer was refused by the Austrian Syndicate, who desired a fixed period of time to be agreed upon. A struggle was then begun on both sides, in order to lay stress on their demands. The Westphalian iron works sent bar iron into Austria at prices considerably lower than those quoted in that market. On the other hand, the Austrian Syndicate replied by underbidding the prices quoted in the German trade districts, and offered bar iron to Saxony and Bavaria at 10 marks (exclusive of customs duties), or about 3 marks below the German prices. A settlement on this basis appears unlikely to be arrived at either in Germany or in Austria. The German Union of Rolling Mills sent a delegate to Vienna to treat for a peaceful solution of the difficulty. The Austrian Syndicate wishes for the renewal of the agreement without any alteration, so that Austria should not sell goods to Germany, nor Germany to Austria, and that the supplies from the Silesian and Hungarian works, and Wittkowitz to the Balkans, should be regulated according to the old conditions. The desired result has not yet been arrived at, but a truce prevails for the present. A reduction in the prices of all those articles which are subject to foreign competition is evidently expected. Bar iron alone, for which there is a large demand in consequence of the activity of the building trade, shows no signs of a reduction; but a considerable lowering of prices in plates of every sort has become necessary.—The manufactory of arms in Steyr has concluded an agreement with the Government of Saxony for the delivery of 65,000 arms.—The Gotthard Railway has ordered a locomotive here, which will be one of the largest yet built. It is 14 metres long, can carry 12 tons of water and coals, and, when fully loaded, weighs 84 tons. Its power is about 800 h.p.

The Sugar Market.—Strong prices prevail in the sugar market. Trade has been exceptionally brisk during the recent market days, and large quantities of raw sugar for North America were taken off the market. This occasion has been utilised by speculators for the formation of new companies, and recently a syndicate has been formed to erect a large sugar manufactory in Aussig (Bohemia). The title of the company is "The English-Austrian Sugar Refining Company, Limited," and consists mainly of English firms. Its representative in Austria is Mr. Carl Steffen, who has obtained both wealth and fame by his discoveries in this branch of industry.

City Railway in Vienna.—A project, which has been worked out by the Ministry of Commerce, for the construction of a railway in the city, is now being considered in the office of the General Superintendent of Railways. This railway already partly exists in the Government railways connecting the stations of Vienna. This project may, therefore, ultimately be authorised.

BRUSSELS, February 17th, 1891.

Metals.—The price of iron shows a tendency to become stronger, and some considerable projects seem on the point of being carried out. Rolling mills and manufactories are receiving some orders, as well as some offers, from abroad. Several mills have plenty of work, and the price is quoted at from 125fr. to 130fr. In general, prices are not remunerative, but manufacturers are well employed, and hope that a change in the price of coal will better enable them to meet the situation. There are plenty of orders for rolling stock and iron bridge frames. Steel works have a good supply of orders for rails and sleepers. The pig iron market remains unaltered. Prices do not vary, and the amounts which still remain to be delivered on previous contracts are sufficient to take all the production for several months. Red short iron of Charleroi is quoted at 47fr. to 48fr. Messrs. Cockrell have sufficient orders on their books for several weeks. Messrs. Angleur are actively engaged in the manufacture of sleepers for Porto Rico, and of rails for the Belgian Government. Messrs. Ougrée have had some important orders from abroad. The Industrial Society of Louvain have received an order for a supply of bridges for the Congo. The prices of iron are as follow:—Sheets, No. 1, 135fr.; No. 2, 155fr.; No. 3, 175fr.; No. 4, 275fr.; joists, 135fr.; angles, 137fr. Cast iron—Luxembourg, 57·50fr.; Charleroi, No. 3, 85fr.; scrap iron, 52fr.; red short iron, 48fr. Steel rails, large sections, 122·50fr.; small sections, 145fr.

The Coal Market.—The market is weak, even for household sorts, in consequence of the advancement of the winter season and of the depressed state of the iron and glass manufactures. The prices of industrial sorts are uncertain, as buyers hold back and wait for a fall in prices. The prices for close burning sorts is 14fr. to 16fr.; small sorts, 9fr. Coke remains at 16fr. to 18fr., small sorts at 10fr. to 10·5fr., and briquettes at from 16fr. to 18fr. The buying of *demi-grasses* for sugar work has commenced, and the price appears to be 17fr. for delivery in France, or a reduction of 1fr. on last year's price. Coal for manufacturing purposes, in which the trade usually becomes brisker during March, is quoted at 27fr., which is the same price as last year.

DÜSSELDORF, 17th February, 1891.

Iron and Steel Market.—The pig iron market is rather quiet, and all those who had hoped for an improvement of prices through the favourable state of the money market have been disappointed. The quotations of best forge pig are rather lower, in spite of the fact that the Siegerland Company has booked several heavy orders of spiegel containing 20 per cent. of manganese. Steel works continue in full operation; the Georgsmarienhütte has obtained an order for steel rails at 131 marks from the Hanover State Railway Direction. Makers of bar iron, wire, and plates are eagerly looking for new orders.

The Coal Market.—Notwithstanding the present warm weather the scarcity of waggons continues to be widely experienced, and there is a deficiency almost every day of from 2,000 to 3,000 cars in the Ruhr district. Prices are rising.

Traffic on the Prussian State Railways.—The following interesting figures have been taken from the official report on the traffic of all the railway lines under the management of the Prussian State:—

	1888–89.	1889–90.	Increase in 1889–90.
"Passenger-kilometres" in millions	5,951	6,706	755 or 12·7%
Receipts from passenger traffic in millions of marks	195	213	18 or 9·2%
Passenger cars in service	13,776	14,383	607 or 4·4%
"Tons-kilometres" of goods of all kinds in millions	13,194	14,203	1,009 or 7·7%
Goods waggons	177,541	186,832	9,291 or 5·2%
Locomotive engines	8,711	8,961	250 or 2·9%

From these figures it is evident that during the past year the traffic has increased at a much quicker rate than the rolling stock. The difficulty caused by the scarcity of waggons has been predicted for a long time past by manufacturers. It has inflicted great damage on the German industries, and there exists amongst traders generally a strong feeling against the bureaucratic system of Mr. Maybach, the Prussian Minister of Public Works.

AMSTERDAM, 16th February, 1891.

The Blitong Tin Company.—The Government has been rather severely attacked in the First Chamber for attempting to enforce upon the company some manifestly unfair terms in its concession, which would have given to the State an unduly large share in an always risky mining speculation, and would have left very little profit to the actual workers. It is urged that the Government should initiate another and more equitable agreement. Before doing this, the Government has determined to hold another inquiry into the matter, for which purpose a high Government official will proceed to Blitong in order to make a local investigation.

The Sewage of Amsterdam.—Very important experiments have been conducted in Amsterdam with that portion of the sewage which is treated in accordance with the so-called Liernur system, which consists of deodorising and utilising the fæces for industrial and agricultural purposes. At the Central Pumping Station, in the course of an experimental year, 10,000 cubic metres of sewage matter were treated by the contractor, Mr. Lambert Ketjen, manufacturer of sulphuric acid. The treatment resulted in a gross profit of over 3,000 guilders. An amount of 8 per cent. was written off, and 5 per cent. dividend reserved on the capital employed—viz., £1,000. There remained an available balance of 1,463 guilders, to be divided in equal moieties between the Town Corporation and the contractor. The experiments having been so eminently successful, both from a financial and a technical point of view, the town authorities of Amsterdam have now proposed to make an agreement for ten years with the said Mr. Ketjen, which agreement he shall be at liberty to transfer to a company as soon as it shall have been approved by the Town Council. The gross profit is to be equally divided between the town of Amsterdam and the concessionaires. The concession is to last ten years, after which term all the apparatus will be taken over by the Town Corporation at one-half the original cost price, the concessionaires in the mean time being required to maintain everything in a state of efficient repair. The carrying into effect of this agreement will necessitate upon the part of the town of Amsterdam an expenditure of 27,000 guilders.

Railways.—The Holland Railway Company has submitted to the consideration of the Dutch Government a new system of passenger fares, which will permanently fix them at a much lower level than they are at present. The originally Hungarian "zone" system has not suggested the new

Digitized by Google

method, although it is no doubt akin to it. The directors of the Holland Railway Company propose to divide their mileage into sections. Up to 50 kilometres the fares would remain practically what they now are, but beyond 50 kilometres fares would be lowered considerably, especially for return tickets. The "zone" system does not admit of this reduction, but in the case of the Holland Railway Company it will form the basis of the new development, as 85 per cent. of all travellers in Holland are holders of return tickets.

STOCKHOLM, 14th February, 1891.

The Sawmills and Timber Export Society.—This Society held its annual meeting on the Stockholm Exchange on the 10th inst. In the report it was stated that the prices of timber, in consequence of a surplus of sawn timber having been held over from the previous year, and favourable floating-down conditions, had fallen to a very low figure. When it became manifest that over-production was the real cause of the decline in prices, the Society determined to forward to all the sawmills and exporters of timber in the country a request to reduce the cuttings for this winter. The result of this application was that all owners of sawmills undertook to reduce their production to some 30 per cent. of that of last winter. From calculations it appears that the available quantity of sawn timber will be less by 39,130 standards at open water this year than what it was last year. Among the matters discussed was the question of mode of payment on sales to England, and a general desire was expressed that the time of six months should be reduced.

New Steamer.—A new steamer, "A. Wijkonder," built at the Lindholmen Engineering Company's shipyard, had its trial trip on the 5th inst. The dimensions are:—Length, 217ft.; breadth, 29½ft.; carrying capacity, 1,700 tons. The engines indicate 650 horse-power. The trial trip was in every respect satisfactory.

The Herring Fishing.—The herring fishing on the west coast has not been so good of late. The exports from November last year to February this year amounted to 10,396,000 kilogrammes, against 13,069,000 kilogrammes during the same period last winter. The State railways had forwarded 7,600,000 kilogrammes, against 10,000,000 kilogrammes during the same period of last winter.

Electric Transmission of Power.—Transmission of power by electricity is being adopted at the Skutskör Saw mills. The engine which is working the large pumps will be abolished, and the requisite power is to be transmitted by electricity from one of the large engines. The power in question is 8 h.p., and the distance about 2,000ft.

CHRISTIANIA, 14th February, 1891.

The Wood Pulp Industry.—The past year was by no means a favourable one for this important industry, which has, in fact, developed so quickly that the consumption has hardly been able to keep pace with the supply. Prices have during 1890 reached a lower point than was thought possible a year or two ago. Both buyers and sellers, especially the latter, have been well stocked. Buyers have been holding back, and the manufacturers have had to sell in several cases at unremunerative prices. Wet 50 per cent. mechanical wood pulp has been sold at £1 12s. 6d. per ton, delivered in English ports. Efforts were, therefore, made to bring about a better state of affairs by a reduction in the output. This was also agreed upon in August last, when it was decided to stop the works from Saturday noon to Monday noon by a large number of wood pulp manufacturers in Norway and Sweden, but a good many Norwegian makers were prevented by pending contracts from joining this arrangement. It is, however, to be hoped that this movement will include all Scandinavian wood pulp manufacturers, whereby it will gain in strength and effect. An improvement in the demand, attended by somewhat better prices, began in November, enabling the makers to clear the bulk of their surplus stock. America is virtually a closed market for foreign wood pulp, owing to the new tariff, but this is not a matter of great importance. The complications in connection with the French and Spanish commercial treaties are far more serious, as the former country, especially, is a large buyer of Norwegian wood pulp. The exports of wet mechanical wood pulp were about 205,000 tons in 1890, 190,000 tons in 1889, 175,000 tons in 1888, 155,000 tons in 1887, 115,000 tons in 1886, 100,000 tons in 1885. These figures show an uninterrupted and fairly regular increase. There are at present in Norway altogether fifty-four manufactories where mechanical wood pulp is being made.

COPENHAGEN, 14th February, 1891.

The Copenhagen Waterworks.—The works in connection with this pumping station have progressed rather slowly, owing to the strike last year and the severe frost of the present winter. The installation of machinery is, however, expected to take place about the beginning of March, and the station will probably be ready for work by the 1st of May. This new pumping station will increase the daily water supply from 210,000 barrels to about 350,000 barrels, and at the same time provide a reserve for the old waterworks. It is thought that the fact of drawing part of the daily supply from the new pumping station will not perceptibly increase the cost per 1,000 barrels, as the new station will be more economical than the old one.

Breweries.—The Tuborg Brewery, which is a limited company, made last year a profit on its brewing of 244,322kr., against 276,494kr. the previous year. At the annual meeting this decrease was explained as due to the cold and wet summer of last year, and the inferior quality of the malt. In addition to profits on beer, the company had derived various other profits from its harbour, its workmen's dwellings, and its petroleum stores. The net profits amounted to 99,824kr., of which 96,000kr. were absorbed by the payment of a 6 per cent. dividend to the shareholders. The question of the effect of the proposed beer tax was touched upon. The tax is an extraordinary one, and affects only one class of beer. If it should be imposed, the breweries will probably have to produce another kind of beer which is exempt from taxation.

Danish Industries.—Though the industries of Denmark are not so important in extent as those of some other countries, only about 14 per cent. of the population being engaged in industrial pursuits, the extreme care shown in the manufacture has led to many successful results. The Royal Porcelain Manufactory is one of the most flourishing of these industries. It was originally started by a private individual in 1775, and was shortly after taken over by the State, for whose account it was carried on up to 1867, when it again passed into private hands. In 1882 it was purchased by the Aluminia Company of Copenhagen, whose earthenware factory adjoins, and which has been successfully carried on under the management of Mr. W. Edwards, an Englishman, who brought into the business his experience gained in the Potteries. Since its foundation the Royal manufactory has confined itself to the production of hard porcelain (*porcelain dure*), the principal components of which are kaolin quartz and feldspar.

MADRID, 16th February, 1891.

Export of Iron Ores.—The export of ores from Bilbao up to the present time is about 30 per cent. below the export of last year. This deficiency is owing to the severe weather, which has caused difficulty in the workings. The total export during the present year is not likely to amount to that for the past year.

Bridge over the Nervion.—This interesting bridge over the River Nervion, from Portugalete to Las Arenas, will be high enough to allow the largest vessels to pass under it. The material for the bridge is daily expected at Bilbao, and the bridge will be erected as soon as possible so that it may be opened before the second cruiser is launched in September next. The contract for the metal work has been carried out by a French works, under the management of M. Arnodin. The shore supports of the bridge are 65 metres high, its length is 160 metres, and height from the level of the highest tides to the girders is 45 metres. Two ways of crossing from one shore to the other will be provided — a movable platform, to which there will be access on a level with the shore, and a footpath over the bridge, which will be reached by lifts like those employed in the Eiffel Tower. The total cost of the bridge will be about £12,000, and it is expected that a fair interest will be paid on the capital. In case of success another bridge will be built higher up the river.

The New Railway Station at Madrid.—The new railway station, which is being constructed by the Madrid, Zaragoza, y Alicante Company is making rapid progress, and will be a very fine building. The company has nearly 3,000 kilometres of lines. The length of the station will be 152 metres, and the span over the platform will be 50 metres. There are ten platforms at a distance from each other of 17 to 18 metres. The height from the rails to the centre of the arches is 25 metres, and the station covers 7,500 square metres of ground. The steel portions of the structure have been constructed by the Belgian Company "Société Anonyme de Construction et des Ateliers de Willebroeck." Mr. Leon Beau is the representative of the company in Spain.

Improvements at Barcelona.—Tenders for the extensive improvements which are to be carried out at Barcelona, and which may be compared to those made at Paris under the Empire, are to be received on May 27th. Several thousand buildings are to be pulled down, and many new streets are to be erected in their place. There is much risk in the conditions of the contract, as a slight alteration in the value of the property to be bought and sold would result in financial loss. The only tender, which is likely to be sent in, is that of the author of the scheme, as he has the right of undertaking the contract at the lowest of the tenders.

NEW YORK, 7th February, 1891.

Lead.—The annual meeting of the stockholders of the Lead Trust was held here on the 4th inst. Representatives of about $50,000,000 of the stock out of a total of nearly $90,000,000 were present. A dividend of 50c. a share was declared, and it was announced that that amount would be paid quarterly hereafter. The net earnings of the year after all expenses are deducted amount to $2,028,552. The company or trust controls a large share of the sheet lead business, and also of the white lead business, but they have strong competition. About one-eighth of all the linseed oil business and one-eighth of all the smelting and refining business done in the United States is under their control. The valuation of the properties of the trust on January 31st was $24,217,638, of which their investment in plant amounted to $17,992,989, and their net working capital to $5,765,414. The total sales made by the trust during the year amounted to $19,898,835.

Copyright Decision.—The decision of the judge of the United States Circuit Court in New York probably settles the long litigation over the right to reprint the "Encyclopædia Britannica" in this country. He refused to prohibit the sale of the American pirated edition, on the ground that the British publishers had no rights in the United States except as to certain articles in the "Encyclopædia" which were written and copyrighted here. As the American publishers had substituted other articles for those, there was nothing to prevent their selling their edition.

Carnegie's Steel Works.—A connecting bridge is to be built by Carnegie Bros. & Co., and Carnegie, Phipps, & Co., from the Homestead Steel Works to a point on the north side of the Monongahela River near the Carrie furnaces, at Keating Station, Pa. The object is to establish direct communication between the two plants. It is said that the direct process of manufacture now in vogue at the Edgar Thomson works will be introduced at Homestead. The iron will be taken in a molten state over the bridge from Braddock in vessels.

Pumping Machinery.—The Snow Steam Pump Company, of Buffalo, New York, is about to ship to the Montreal Mine, Hurley, Wisconsin, one of its improved mine pumps, having a capacity of 100,000 gallons per day, the water to be raised 1,500ft. Among other recent orders was a 200,000 gallon elevator pump for the new Rockefellar & O'Day building in Buffalo.

The Berlin Iron Bridge Company.—The business of the Berlin Iron Bridge Company, of East Berlin, Conn., has increased so rapidly in the last few years that at the annual meeting recently held the shareholders decided to increase the capital from $125,000 to $300,000. The entire increase has been subscribed for by the present shareholders. The additional capital will be used to improve the plant at East Berlin, and the company will immediately put up a new building 80ft. wide by 600ft. long, and expects to have it in working order by July next. The addition is expected to increase the output of the works 25 per cent., with the shop running 10 hours per day. The works have been running night and day for a large portion of the last three years. The company has shipped during the past year 8,000 tons of iron work, consisting of iron bridges, iron buildings, and iron roofs.

PHILADELPHIA, 6th February, 1891.

A Philadelphia Pipe Line.—The largest oil pipe line leading into Philadelphia will be completed during the present week. It extends from Morgantown, the centre of the Doll's Run and Mount Morris oil field, to the works of the Atlantic Refining Company in this city, and will have a capacity of 15,000 barrels of oil per day. These oil fields in South-Western Pennsylvania and Northern West Virginia have proved very productive, and the oil is of excellent quality. The Standard Oil Company has but little interest in the territory as an operator, but all the oil passes through its pumping station at Moyertown, where the tanks of that company have a capacity of half a million barrels. The average daily output of these fields is 5,000 gallons per day.

Pumping Engines.—The tenders for pumps, with a capacity of 20,000,000 gallons, for use at the Spring Garden station of the city water works were opened this week. The Holly Manufacturing Company bid $81,000, agreeing to complete the work by February 1st, 1892; the Southwark Foundry and Machine Company, $72,500, to complete in nine months from date of order; the Worthington Pump Company, for $127,000; and the I. P. Morris Company, $83,400. The tenders for boilers were $19,900 by the I. P. Morris Company, $23,165 by the Henry Worden Company, and $18,865 by the Southwark Foundry, to the latter of whom the contract was awarded.

Locomotives. — The Baldwin Locomotive Works, of Philadelphia, Pa., have delivered three freight engines to the Central New England and Western Railway Company, and they are building two eight-wheel and two ten-wheel engines for the Los Angeles Terminal Company. The Rhode Island Locomotive Works, of Providence, R.I., have delivered four ten-wheel engines to the Union Pacific. The Schenectady Locomotive Works, of Schenectady, N.Y., has an order for freight engines for the New York Central and Hudson River. The Rogers Locomotive Works, of Paterson, N.J., are building three decapod engines for the Chicago, Burlington, and Quincy. The Cincinnati, Hamilton, and Dayton has put on two powerful Mogul freight engines, weighing about 65 tons. The Rogers Locomotive and Machine Works, of Paterson, N.J., have delivered four eight-wheel passenger engines to the Louisville, New Albany, and Chicago. The Brooks Locomotive Works, of Dunkirk, N.Y., have an order for ten ten-wheel engines for the New York Chicago, and St. Louis; they will have cylinders 19in by 24in., and driving wheels 50in. diameter, and will be fitted with the Westinghouse air brake and American steam brake. The Grant Locomotive Company is said, according to the *Engineering News*, to be at work on the construction of its plant at Cicero, Ill.

THE WORLD'S MONEY.

Mr. Leech, the Director of the United States Mint, has prepared for the House Committee on Coinage a series of interesting tables, showing the gold and silver estimated and officially reported to be in circulation as money throughout the world, and the specie holdings of the leading European banks. The most comprehensive table, which is given in the *Iron Age*, is the following:—

Approximate Amount of Gold and Silver Money in the World.

Country.	Gold.	Silver.
United States	$702,018,869	$482,071,346
United Kingdom	550,000,000	100,000,000
France	900,000,000	700,000,000
Germany	500,000,000	145,000,000
Belgium	65,000,000	55,000,000
Italy	140,000,000	60,000,000
Switzerland	15,000,000	15,000,000
Greece	2,000,000	4,000,000
Spain	100,000,000	125,000,000
Portugal	40,000,000	10,000,000
Austria-Hungary	40,000,000	90,000,000
Netherlands	25,000,000	65,000,000
Scandinavian Union	32,000,000	10,000,000
Russia	190,000,000	60,000,000
Turkey	50,000,000	45,000,000
Australia	100,000,000	7,000,000
Egypt	100,000,000	15,000,000
Mexico	5,000,000	50,000,000
Central American	—	500,000
South America	45,000,000	25,000,000
Japan	90,000,000	50,000,000
India	—	900,000,000
China	—	700,000,000
The Straits	—	100,000,000
Canada	16,000,000	5,000,000
Cuba, Hayti, &c.	20,000,000	2,000,000
Totals	$3,727,018,869	$3,820,571,346

The silver money is classified by Mr. Leech, in the following table, into that which is full legal tender and that which is tender for but limited amounts:—

Country.	Full Legal Tender.	Limited Tender.
United Kingdom	—	$100,000,000
France	$ 650,000,000	50,000,000
Germany	102,000,000	43,000,000
Belgium	48,400,000	6,600,000
Italy	25,800,000	34,200,000
Switzerland	11,400,000	3,600,000
Greece	1,800,000	2,200,000
Spain	90,000,000	35,000,000
Portugal	—	10,000,000
Austria-Hungary	90,000,000	—
Netherlands	61,800,000	3,200,000
Scandinavian Union	—	10,000,000
Russia	22,000,000	38,000,000
Turkey	—	45,000,000
Australia	—	7,000,000
Egypt	—	15,000,000
Mexico	50,000,000	—
Central America	500,000	—
South America	25,000,000	—
Japan	50,000,000	—
India	900,000,000	—
China	700,000,000	—
The Straits	100,000,000	—
Canada	—	5,000,000
Cuba, Hayti, &c.	1,200,000	800,000
Totals	$2,929,900,000	$408,600,000

The total stock of full legal tender silver coin in Europe is given at $1,101,400,000.

THE INSTITUTE OF MARINE ENGINEERS.

A meeting of this Institute was held on the 10th inst., when Mr. W. W. Wilson read a paper on "Improvements in Engine Room Practice." The meeting was presided over by Mr. J. McFarlane Gray. The first detail of the engine discussed was the piston, the different styles of which were referred to, and the adoption of the Ramsbottom rings was considered to be a very great improvement. The valves, eccentrics, shafting, thrust blocks, boiler mountings, and safety valves were mentioned, and the difference between the old and new systems pointed out. The Chairman commented upon the excellent paper which had been given, and the discussion was maintained by several members.

The series of questions recently propounded by the Admiralty Engineer to the engineers of the mercantile marine, regarding the practice in connection with the working of boilers and the feed-water arrangements, were given for discussion. It was stated, in reply to the first question, that boilers had been run for about five months with the same water, or without emptying them. The other questions were also dealt with, and it was explained that in the most recent types of marine machinery provision was made for supplying the loss of fresh water by means of evaporators, by tanks built in the engine-room or stokehold, and by purchasing fresh water at ports of call, or supplementing it by means of the donkey boiler. It was explained that the supply of steam to baths and sculleries, and leakages, were the chief sources of loss of fresh water in steam vessels, and that these amounted generally to more than three tons per day.

The next meeting will be held on the 24th inst., when Mr. Green is expected to read a paper on the "Application of Zinc for the Preservation of Boilers."

TRANSFORMER DISTRIBUTION.*

The distribution of electrical power by means of alternating-current transformers can hardly be considered to have reached its final state, and though it may be somewhat difficult to say what system will be in general use ten years hence, there is little doubt that present practice will be largely superseded.

The method now in vogue is simple: it consists of running several independent dynamos, each with its own engine; each dynamo supplies a few high-pressure mains, which branch off, and supply transformers placed in the houses, or wherever light is required. This system, admirable for country towns or straggling villages, is hardly likely to be permanent elsewhere. It has many disadvantages. Except that all the dynamos and engines are in one building, it is nothing more than a collection of little independent installations. Each engine and dynamo supplies its own circuits, which are independent of all the others. In cases of a breakdown of an engine or dynamo, and in many cases of the leads, there is a stoppage till new arrangements can be made at the station. In addition to this, great lengths of high-pressure conductor are required, and this leaves openings for breaking down of insulation. The introduction of high pressures in private houses is dangerous if not well managed, and is in any case expensive, demanding compliance with all sorts of regulations, rendered necessary for the security of the public. The greatest drawback to the present system, however, lies in the waste of power in the transformers themselves. For a long time transformers were supposed to have an efficiency of about 98 per cent. More will be said on this subject presently.

It must be borne in mind that in spite of the drawbacks of the present system of putting transformers in houses, it may be, and probably has been, advisable for electric light companies to begin on that system, even in such places as London; but I do not think such an arrangement will pay in the long run, and a time will arrive when the mains will have to be changed and a low-pressure supply system substituted. When an electric light company begins, it has to take on houses here and there, where it can get them; but if its district is populous and wealthy, it should soon be enabled to work on some low-tension or sub-station system; and then the question is whether it is not better to lay the low-pressure mains at first, instead of beginning on one system and changing to another. Probably none of the existing companies mean to change from one system to another. Their engineers have no doubt gone into the merits of the particular cases, and have come to their conclusions with great deliberation, and I do not think it well to offer any criticisms lightly.

Parallel Running According to Orthodox Hypothesis.

To begin at the beginning of my somewhat extensive subject, the first question is that of running machines in parallel. There are few matters of greater importance to engineers, and few on which opinions differ so widely. One says that machines will not run in parallel unless they have large self-induction; another that it is necessary to have iron in the armatures; another that they will only run together if they have no self-induction, or as little as possible. Others say that there is no difficulty in running them in parallel. No engineer who employs direct currents denies the advantages of running machines in parallel; if independent running is advisable in alternate systems, it is equally advantageous in the case of direct currents, and direct-current stations should have separate circuits for each little district, each district being run by one dynamo. I do not think, therefore, independent running is advisable.

In 1884 Dr. Hopkinson showed that alternate-current dynamos could be run in parallel, or could be run as dynamo and motor, and even that a machine giving a high pressure could be run as a motor off a circuit of lower pressure. In his paper he assumes that machines have "self-induction." He points out that the self-induction varies, but that it would be impossible to work out the calculations if the "self-induction" were taken as variable. For some reason or other, Dr. Hopkinson's calculations have received little application. That is to say, engineers have not taken actual cases and worked them out. Calculations have been made in which the various quantities have appeared in the form of letters, and diagrams have been drawn in which they are represented by lines whose lengths have been chosen at random. The geometrical treatment of many problems of this kind shows most of the actions very clearly to students, but is not always of value in practical work, as in most cases some lines are so long and others so short that it would be difficult to avoid large errors. The result of this is that few of us, if any, have had any definite idea of how much "self-induction" a machine should have to make it work well in parallel with others. The general impression is that it is somewhat difficult to design a machine whose "self-induction" is large enough, and that most failures to run in parallel are due to deficiencies in this respect. I am using the term "self-induction" under protest, as I prefer to look at the question from another point of view. But, whatever goes on in a dynamo, if the no load electromotive force is treated as constant, a value for a constant coefficient of self-induction can be assumed which would produce results somewhat similar to those found in practice. To overcome the difficulties arising from deficient self-induction in the armature circuit, Dr. Hopkinson has proposed to insert it artificially, in the form of choking coils, or to use induction couplers to compel synchronism. Without knowing that it had been done before, I described a similar arrangement to the Institution a few years ago.

In the spring of 1890 Mr. Mordey read a most important paper, in which he described some experiments on alternate machines. He argued from them that self-induction was deleterious, and that machines would run together best if they had none. In the discussion, Dr. Hopkinson pointed out that the experiments were quite in accordance with his theory, and that there was nothing that could not be foretold by it.

To begin with, it is necessary to get a clear idea of what is required for parallel running. It is not exactly the same as the case of alternating motors, neither is it the same as two machines of equal pressure coupled in parallel by themselves. If all the machines are coupled to two main conductors, we may consider them one at a time, and take each dynamo as coupled to a system whose pressure and variations of pressure are independent of it. Suppose the effective pressure to be 2,000 volts, for example: we have to consider a pair of mains with 2,000 volts, and we have to couple on a dynamo to add so many amperes to it. Such a machine must not be excited to give 2,000 volts on no load, being then thrown into circuit with full steam turned on immediately afterwards. It should be excited to give somewhere about half load with 2,000 volts at the terminals, and should then be thrown in. Steam can then be turned on, and the excitation raised to its normal value. The machine should be so designed that any excessive power that the engine may give shall not only not throw the machine out of step, but shall not increase the armature current to such an extent as to damage the insulation by excessive heating.

The power absorbed by a dynamo working on a parallel system is

$$P = \frac{B^2 r}{2 i^2} - \frac{A B r}{2 i^2} \cos 2\pi n \tau + \frac{A B L}{2 i^2} \sin 2\pi n \tau,$$

where A is the maximum station electromotive force—that is to say, the station pressure is $A \sin 2\pi n t$ — B is the maximum "impressed" electromotive force in the armature, r is the armature resistance, i the impedance of the machine, and τ the angle of lead. This equation is taken from Dr. Hopkinson's paper. When the dynamo is doing its proper share—that is to say, under normal conditions—

$$B = I c,$$

where I is the impedance of the whole circuit when the machine is isolated, and working at full load on an external resistance, and c is the maximum value of the current. To find how much the driving power may increase for a small increase of current, we may differentiate with respect to c, and then find the value of L which makes the result a maximum.

$$c = \sqrt{\frac{A^2 + B^2 - 2 A B \cos 2\pi n \tau}{i^2}},$$

$$\text{Cos } 2\pi n \tau = \frac{A^2 + B^2 - i^2 c^2}{2 A B}.$$

So,

$$\frac{d P}{d c} = \frac{A B r}{2 i^2} \cdot \frac{2 c}{A B} + \frac{A B 2\pi n L}{2 i^2} \cdot \frac{d \sin 2\pi n \tau}{d 2\pi n \tau} \cdot \frac{d 2\pi n \tau}{d \cos 2\pi n \tau} \cdot \frac{d \cos 2\pi n \tau}{d c};$$

and in the case of a dynamo working on resistance, or on a station load when supplied with just its right share of power,

$$\cos 2\pi n \tau = \frac{A + r c}{B},$$

$$\text{and cosec } 2\pi n \tau = \frac{B}{L c}.$$

So,

$$\frac{d P}{d c} = \tfrac{1}{2} A + c r,$$

c being the maximum, not the effective current. It will be observed that L has disappeared altogether.

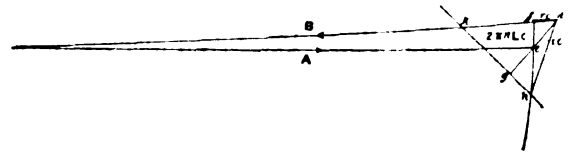

Fig. 1.

This shows that for a very small increase of power the increase of current will be the same, whatever the self-induction of the machine may be. It would not matter if the machine had none. A machine with no self-induction would (Mr. Mordey notwithstanding) short-circuit the mains if the engine supplied too little power; in fact, at full load it would be giving its minimum possible output, and any attempt to diminish this would be disastrous.

Discussing the question of a very small increase is not exhaustive; an engine may supply a large proportion more than its share of power to one machine. For instance, suppose it supplies twice the normal power. Many engines could not give such an excessive power, but in others which have expansion gear controlled by a speed-governor, it is easy to get double power if the station is running at a slightly slower speed than that for which the governor is set. These matters are always made much clearer by taking practical examples and working them out. The great difficulty is to obtain accurate data. I should prefer to discuss such machines as those described in Mr. Mordey's paper read here a short time ago. Without wishing to say anything in disparagement of his excellent paper, I must point out that an account of experiments should contain full particulars of the machines on which the experiments were made. Such omissions are exceedingly common in electrical papers. Mr. Mordey has not given us the details of the field magnets, air space, armature coils, or exciting coils; he has not even given us the currents in the different experiments. I have found similar omissions whenever I have tried to gain information from any of the numerous experiments which have been made on alternate machines in America. Mr.

* Abstract of a paper read by Mr. J. Swinburne before the Institution of Electrical Engineers on the 19th inst.

Digitized by Google

Mordey does, however, say that about half the drop in his machines is due to resistance, and half to self-induction. The machines give an output of 2,000 volts and 20 amperes, and when fully excited give 2,200 volts at no load. This would correspond to a self-induction of 0·05 henry.

Suppose, first, that the self-induction were such that $2\pi n L = r$: on increasing the power supply, the effective current increases evenly, and when the power supplied to the machine is doubled, the effective current is only about 44 amperes. It is necessary, however, that the machine should stand decrease of load, as well as increase, without injury. Keeping the same self-induction, let us decrease the load to zero with the full excitation on. The current gradually diminishes to just below 15 amperes, and then increases to just over 20 again. These figures are extremely troublesome to work out from Dr. Hopkinson's equations, as the angle is so small that an error in about the sixth place of decimals will vitiate the results.

Many people prefer diagrams such as those used in mathematical books when dealing with harmonic variations. Mr. Blakesley has applied these diagrams to the discussion of alternate dynamos and motors, and Messrs. Kapp, Fleming, and others have applied them too. The chief drawback is that it is not always easy to draw such figures to scale. They are generally drawn with the values taken at random, to give ideas of the principles involved. So far as I know, no scale diagram of this sort has ever been published. In the case of the 40,000-watt machine such diagrams can be applied; but with 100,000 machines, which will probably be the standard size, the diagrams are almost illegible.

Fig. 1 is a diagram to scale. The lines are all rotating positively. The diagram is made as follows:—The pressure in the mains A is drawn first. Instead of the maximum, it is simpler to draw the effective pressure—in this case 2,000 volts. From the end e, $2\pi n L c$ is drawn at right angles to it to f; and then $r c$ from f, parallel to A, B, is drawn to join the ends of A and $r c$, as shown. The lines are all pressures; but the instantaneous current is in step with the pressure $r c$ and with the pressure A, so that the power is proportional to $B r c \cos f d m$. I use the expression "in step" to mean co-phasally synchronised. Thus two machines may be running at the same speed without being in step; just as soldiers may take the same number of paces per minute without being in step.

To find the current at double load, produce $i c$ to g, so that $d g = 2 i c$. Through g draw a straight line cutting B at k, at an angle, $g k d$, equal to the angle $d e f$. The line $g k$ is the locus of the end of the line representing the pressure spent over the resistance and self-induction of the armature with currents giving double load. It is unnecessary to go into the proof of this. With m as centre and A as radius, describe arc cutting $k g$ at h; join $d h$. Then the current at double load is to 20 amperes as $d h$ is to $d e$. In this case the double-load current is not much more than 40 amperes.

(To be continued.)

SHIPBUILDING NOTES.

On the 10th inst. H.M.S. "Latona," a second-class cruiser, built and engined by the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, underwent her forced draught trial at Portsmouth, when the result was most satisfactory. She is the first of her numerous class now building which has been delivered to the Admiralty. The horse-power contracted for under forced draught was 9,000, but this was exceeded by 438 h.p. Both her natural and forced draught trials reflect much credit on her constructors, and the Admiralty are to be congratulated upon having such an efficient vessel as the "Latona" has proved to be.

On the 10th inst. the steel steamer "Agnes" was launched by Messrs. R. Craggs & Sons from the Castle Moat Shipyard, Stockton. She is of the following dimensions:—Length, 173ft.; breadth, 26ft.; depth, moulded, 12ft. 11in.; and will be fitted by Messrs. Westgarth, English, & Co., Middlesbrough, with triple-expansion engines, having cylinders 13in., 21in., and 34in., with 24in. stroke. She will be fitted with all the latest appliances for rapid loading and discharge of cargoes.

On the 14th inst. there was launched from the yard of Messrs. W. Doxford & Sons, Limited, Pallion, Sunderland, the s.s. "Clan Macneil," the first of the new Clan Liners, being built to the order of Messrs. Cayzer, Irvine, & Co., managers Clan Line Steamers, Limited, Glasgow. Her principal dimensions are:—Length between perpendiculars, 312ft.; breadth, extreme, 39ft.; depth of hold, 23ft. 6in.; and she will carry about 3,500 tons. He engines are triple-expansion, the cylinders being 23in., 37in., and 62in., with 42in. stroke. The boilers are built for a working pressure of 180lb., and are fitted with Messrs. Howden's force draught system.

Notices of Meetings.

THIS WEEK.

Society of Arts.—Friday, February 20th, at 4.30 p.m. Lecture on "The Science of Colour," by Captain Abney, F.R.S.

North East Coast Institution of Engineers and Shipbuilders.—Friday, February 20th, at 7.40 p.m. Discussion on Mr. A. Blechynden's paper on "The Influence of the Relative Dimensions and Proportions of the Screw Propeller on the Vessel's Performance." Papers to be read: "The Strength of Short Flat-ended Cylindrical Boilers," by Mr. J. T. Nicholson; "Results of Experiments on the Strength of Boilers," by Mr. J. C. Spence.

Junior Engineering Society.—Friday, February 20th, at 8 p.m. Papers to be read: "Carriage Way Pavements in Large Towns and Cities," by Mr. J. B. Ball; "The Design and Construction of Sewage Precipitation Works," by Mr. A. Wollheim.

Royal Institution.—Saturday, February 21st, at 3 p.m. Lecture II., on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

NEXT WEEK.

Society of Arts.—Monday, February 23rd, at 8 p.m. Cantor Lecture II., on "The Electric Transmission of Power," by Mr. Gisbert Kapp, M.Inst.C.E. Thursday, February 26th, at 4.30 p.m. Lecture on "The Economic Development of Siam," by Mr. R. Gordon, M.Inst.C.E.

Cleveland Institution of Engineers. — Monday, February 23rd, at 7.30 p.m. Paper to be read: "Notes on American Blast-Furnace Practice, and a Comparison with the Work Done in the Cleveland District," by Mr. W. Hawdon.

Institution of Civil Engineers.—Tuesday, February 24th, at 8 p.m. Adjourned discussion on the paper by Messrs. Atkinson on "On Electric Mining Machinery." Paper to be read (time permitting): "On the Subterranean Water in the Chalk Formation of the Upper Thames, and its Relation to the Supply of London," by Mr. J. T. Harrison, M.Inst.C.E.

Sanitary Institute.—Tuesday, February 24th, at 8 p.m. Paper to be read: "Scavenging: Disposal of Refuse and Sewage," by Mr. Charles Jones.

Society of Architects.—Tuesday, February 24th, at 7.30 p.m. Ordinary meeting.

PRICES CURRENT, 18th February, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

" Australian	90	2	6	"	90	15	0
" English Ingots	94	0	0			.....	

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: There is practically no change to report in the position of copper, which continues quiet with limited business. Since our last report the market for Chili bars has been weaker, but is now recovering, quotations to-day being £53 to £53 7s. 6d. cash, or about 5s. higher on the week. Manufactured continues steady, at £65 to £66 "strong."

Tin has shown a weaker tendency throughout the week, but to-day's market is firmer.

Lead: Quiet, with values unchanged.

Spelter: The market has kept very steady during the last week, and there has been a slight advance, which seems to be fully maintained. In Silesia the demand for spelter by rollers of sheet zinc has been large, and, therefore, the Continental producers are very firm.

PIG IRON—BRAND "CARRON."

Present prices of "Carron" Pig Iron are as follow:—

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: For bleaching powder there is less inquiry, but other "Union" articles are in good demand. Sulphate of ammonia is quiet, but prices steady. Benzoles in moderate demand. Carbolic acids still very depressed. Sulphate of copper has had a sharp fall, but is again firmer, though the foreign inquiry is very small. Green copperas is more plentiful. Foreign white sugar of lead has advanced strongly, but other qualities have not changed. Recovered sulphur unobtainable on spot, and makers heavily engaged forward.

HOME INDUSTRIES.

LONDON, 19th February, 1891.

The Money Market.—Partly through the continuance of gold withdrawals for abroad, and partly through the action of the Bank of England in taking funds from outside, so as to bring open market rates in line with the official minimum, and thus help to check further withdrawals, money rates have hardened very appreciably during the week. The demand for accommodation now rather exceeds the supply of money, and the maintenance of the firmer rates ruling seems certain for some time to come. Inactivity is still the complaint of the Stock Exchange, the greater dearness of money and the collapse of the price of silver reducing the already diminutive volume of business. The weakness of silver securities has been the only well-marked feature of the week, with the exception perhaps of the depression which has affected the stocks of the Scottish railways. Otherwise there is little to take notice of, markets being in general weak and unsettled. There is a little activity in mining shares, but it is unequal and partial.

British Economic Association.—This Association, which was founded at a meeting held at University College, London, on November 20th, 1890, the Chancellor of the Exchequer being in the chair now numbers about 500 members. The president is Mr. Goschen, M.P.; the vice-presidents are Mr. A. J. Balfour, M.P., Mr. H. C. E. Childers, M.P., Mr. L. H. Courtney, M.P., and Mr. John Morley, M.P.; and the editor and secretary is Professor F. Y. Edgeworth. The object of the Association is the advancement of economic knowledge by the issue of a journal and other printed publications. The *Economic Journal* is to represent all shades of economic opinion, and will be published by Messrs. Macmillan & Co. The first number, to which several well-known writers on economic subjects have promised to contribute, will appear at the end of March next. The first of the additional publications will be a translation of Roscher's History of English Political Economy in the Sixteenth and Seventeenth Centuries. The Association may perhaps extend the scope of its action by supplying a common meeting place for English economists, and by promoting economic investigations.

The Factory Acts Amendment Bill.—On the 12th inst. Mr. Matthews received, at the Home Office, an influential deputation of manufacturers from Lancashire, Yorkshire, and other parts of England, as well as representatives from Scotland and Ireland. Mr. Maclean, M.P., who introduced the deputation, criticised the Bill of Sir Henry James, and said that its provisions had been drawn up with reference to the cotton industry, and were absurd when applied to other textile industries. He complained that the Bill contained certain clauses which both employers and employed had agreed to strike out. Mr. Matthews, in reply, said that he was glad to hear the views of the deputation, as he was himself preparing a Factory Bill. On the 13th inst. Mr. Matthews received a deputation of operatives engaged in the textile industries of Lancashire and Yorkshire. Sir Henry James introduced the deputation, and said that he regretted that no understanding had been arrived at between employers and employed as to the proposed legislation. The operatives agreed with their employers that the latter should not be obliged to disclose facts which would give foreign manufacturers a knowledge of their business, and thus increase competition. Mr. Matthews, in reply, said that many of the technical points could best be settled by operatives and employers, whose interests were, in many respects, identical.—On the 13th inst., also, Mr. Stuart Wortley received a deputation, which asked that the provisions of the Factory Act might be relaxed in favour of the fruit-growing and preserving industries.

Petroleum Fuel.—At a meeting of the Shipmasters' Society on the 13th inst., a paper was read on "Liquid Fuel in Ocean Steamers," by Captain W. V. Carmichael. The lecturer stated that, partly owing to the cheapness of coal, and partly to the reluctance of owners to adopt it, the use of oil fuel had not hitherto been much taken up by steamship owners. An economy of space was effected, since the oil could be carried in the cellular bottom of the ship. Moreover, the fires could be entirely controlled by the engineer on watch. As the consumption of oil, compared with coal, was, weight for weight, one-half—ten tons of coal, in other words, being only equal to five of oil—the storage of fuel could be made much more compact and easier of access; there was increased speed in fuelling the ship; and port charges were avoided, as more fuel could be carried in proportion than formerly. Petroleum was to be found in all parts of the world, and competition would probably bring the fuel within easy reach of the commercial world. With regard to the important question of fuelling our men-of-war at sea during a blockade, he thought that the large tank steamers of the present day could always fuel the fleet, even in heavy weather.

City and South London Railway Company.—The directors of this company state that since the 18th December, when the railway was opened to the public, a service of trains, running at intervals of about five minutes, has been maintained, and although there have been a small number of occasional delays from the failure of engines and other causes, there is every reason to be satisfied with the use of electricity as a motive power. The average number of passengers carried has been about 15,000 per day, but as the weather improves, and the line is better known, this number will no doubt steadily increase. It has been found in working such a rapid service that the siding accommodation provided is insufficient, and arrangements are now in progress for the construction of additional sidings at the Stockwell terminus, which will add greatly to the facilities for working the line. A fourth engine and dynamo will be added to the generating plant at Stockwell Depôt, and these have accordingly been ordered, and it is intended also to add two additional trains and four additional locomotives to the rolling stock. As soon as these additions are complete, it will allow of a considerable accession to the number of trains run, and the opening of the line on Sundays, if thought desirable. With the view of developing the traffic on the line, a Bill has been deposited in Parliament to authorise the construction of a branch line from King William Street to the Bank, and thence, under Moorgate Street, Finsbury Pavement, and the City Road, to the "Angel," at Islington.

The Projected Central London Railway.—A Bill is now before Parliament for the construction of subway railways from Caxton Road, Uxbridge, to Cornhill, at a spot near the Royal Exchange.

MANCHESTER, 19th February, 1891.

The Manchester Association of Engineers.—The annual dinner of this Association was held on the 14th inst. The report which was then read showed that the number of members was 335, and that the balance of profit on the year's working amounted to £190. A successful year in every respect had been passed through, the general attendance at the meetings having increased. The President, Mr. John West, referred to the transfer of the Technical School to the Whitworth Institute, and said that this was a step in the right direction, as it would economise the energies of teachers. Professor Goodman, of the Yorkshire College, insisted on the necessity of workshop practice in the training of engineers, and he urged that it should be of greater duration than the mere collegiate education.

A Prosperous Company.—The half-yearly report of Messrs. Brunner, Mond, & Co. has been published, which shows that during the half year a profit of £154,517 has been made. Of this £132,486 goes in payment of 7 per cent. on the preference, and 40 per cent. on the ordinary shares, £28,829 being added to the reserve, which is thus raised to £200,000. £2,500 is written off the patents account, and £10,539 is carried forward. The assets are valued at £1,509,273, and the liabilities at £1,037,000.

Waterproof Paper.—In our issue of the 26th December last, we gave a short description of a special kind of paper, called "waterproof paper," which we ventured to predict would be of great value for many purposes. The makers of this paper, Messrs. Leech & Horrobin, of Albert Works, Kay Street, Openshaw, are also the makers of liquid waterproof compositions for coating articles such as leather, strapping, machinery, polished steel, brass, and copper, which, it is claimed, will resist damp, heat, cold, and acids. The compositions are colourless, and do not rub or peel off, and are only removable by the application of paraffin or turpentine. We understand that these compositions have undergone very severe tests, and have given general satisfaction.

The Linen and Jute Trades.—The demand this week has been moderate; the shipping trade has been very dull. No change for the better has in fact been noticeable in that quarter for some time, and under the influence of news received by private firms this week from the West Coast of South America the prospects of trade with Chili have become more discouraging. Messages by cable that are worth relying on can only be sent by way of the land wires in Argentina. Nothing coming direct from the offices within the Chilian Republic is allowed to pass without being scrutinised by Government officials. With reference to the demands of firms in the United States, the McKinley Act, although it has not so much affected business in the aggregate, has destroyed trade in certain branches. In the low end there are goods, such as those below 35s. and 40s., on which the duties overlap, the American public being able to buy a better article at about the same price on the basis of the new rates. Jute goods are slightly weaker. The demand for linen threads is brisk, and, though competition is keen, prices are steady.

Portable Bath.—An ingenious arrangement is being put on the market, which is designed to enable a stream of water to be thrown in any direction by means of a pump worked by the feet of the person using the arrangement. A small platform is provided, on which two pedals are fitted in such a way that the heels of the user can rest upon them, and by the pressure set up and a slight muscular action a small pump is operated. This enables the water to be drawn from a vessel detached from the main device and ejected by means of a nozzle. This device is adapted for several purposes, one of which is for a portable bath. In this application the platform is placed in the middle of a tray by which the water can be received after use, and the outlet pipe terminates in a combined brush and rose. The chief feature in this arrangement is that it leaves both hands free, the mere swaying of the body being sufficient to give the necessary power for pumping. The contrivance is also being applied to such purposes as window cleaning, garden sprinkling, and carriage washing. It is the invention of Mr. Donald Noble, of Manchester.

The Calico Printing Syndicate.—With reference to the Calico Printing Syndicate, it may be stated that, although great progress has been made since August last, nothing definite can yet be stated concerning the scheme. Each house, even where formal notice of a desire to join the syndicate has been given, must be dealt with on its own basis, and settlements made by separate agreement. The copper rollers, which form an important item in the assets of the calico printers, will, we understand, be valued at the price of new copper rollers, plus an allowance for outlay on engraving.

GLASGOW, 19th February, 1891.

The Iron Trade.—It is announced that the ironmasters intend to put one-third of the furnaces in blast. The furnaces that are being worked are for the most part supplied with "blackleg" labour. The furnacemen still remain on strike, supported by the Cleveland trade unions, and are holding out for some concession as regards Sunday labour. The opinion is universal that the smallness of the demand at present existing for pig iron has not been equalled in recent years. The prospect of production, even on a limited scale, depresses the market.

Shipbuilding.—Contracts to build two hopper barges for service in South America have been received by Messrs. Murdoch & Murray, Port Glasgow. The vessels will be similar to those supplied by the same firm to the Clyde Trust, and will have a capacity of 500 tons. The engines will be compound surface-condensing, and will be constructed by Messrs. David Rowan & Sons, Glasgow.

The Calico Printing Syndicate.—The English promoters of the Calico Printers' Syndicate have been endeavouring to secure the adhesion of the Scottish firms in the trade. It is quite obvious that unless the extensive firms in the West of Scotland are included in the syndicate there is little chance of its successful formation. The leading firms in this district are the Thornliebank Printing Company, Messrs. Inglis & Wakefield, Messrs. James Black & Co., Messrs. Wm. Stirling & Sons, Messrs. John Orr, Ewing, & Co., Messrs. Archibald Orr, Ewing, & Co., Messrs. John Glen, Guthrie, & MacArly. It seems that some of the firms are indisposed to join the proposed syndicate. In some cases the firms named have already a practical monopoly of the particular class of goods manufactured by them, and in other cases there are special conditions which render it inadvisable for them to ally themselves with the English firms. It is thus doubtful whether the syndicate will receive any considerable support in Scotland. Should the syndicate be formed, however, on an extensive scale, the result of the consolidation of a whole group of industries might be very serious. The group would include the alizarine makers, who have practically been consolidated for many years, the Chemical Union, and now the Calico Printers' Union.

The Glasgow Tramway Company.—This company, whose lease expires in a few years, and whose existence as a company is threatened by the Glasgow Corporation Bill now before Parliament, has petitioned the House of Lords against the measure. The Corporation, who already own the tramway lines, propose to carry on the traffic without the intervention of lessees. The company say that they do not object to the use of mechanical power; but that electricity as a means of haulage is in its infancy, and that the use of cable traction is impracticable in Glasgow owing to the fact that the Central Railway is being constructed so near the street level that there is no room for a cable channel. This is a reason against the use of cables in certain routes, but it is hardly fair to say that the use of electricity for tramways is in its infancy, when in the United States 2,000 miles of track are operated by electricity, and in this country there are twelve separate lines of electric tram or railway.

Minerals.—The arrears of loading, which had accumulated during the strike, are now almost worked off, and the shipments of coal for the past week show an increase of 18,000 tons.—A portion of Messrs. Merry & Cunninghame's properties is being detached from the main concern, and is to be worked by a limited liability company. It will be remembered that a few years ago the whole business of the firm was sold to a company, and was afterwards repurchased by the partners. The property now concerned includes the Carnbrae ironworks and mineral fields, the North Motherwell collieries, Bardykes, Auchenraith, and a number of pits in Renfrewshire.

Jardine's Housing Gear for Rolling Mills.—Messrs. Colville & Sons, of Dalzell Steel and Iron Works, Motherwell, who, some eighteen months ago, had their No. 1 plate mill fitted with Jardine's housing gear, by means of which the four screws regulating the rollers can be actuated by one man, instead of four as heretofore, have, we are informed, found the gear so successful that they have recently had their No. 2 plate mill similarly fitted. As a result, it is stated that the output of this mill last week was the largest it had ever accomplished.

Scottish Railways.—The Yoker and Clydebank Railway Bill, having passed the first reading and the examiners, will shortly be read a second time in the House of Commons.—In the operations in the West End Park, in connection with the new underground railway, the contractors have discovered a seam of coal. The seam, however, is too thin for profitable working.

The Recent Strike.—The postponed meeting between the directors of the North British Railway Company and representatives of the men was held yesterday. The proceedings were conducted in private at the offices of the company in Edinburgh.

Digitized by Google

(From our own Correspondents.)

LIVERPOOL, 18th February, 1891.

The Liverpool Engineering Society.—At a meeting of this Society held yesterday, the President, Mr. F. Hudleston, being in the chair, a paper was read by Mr. H. G. F. Barham, on "Foundations." The author first showed the necessity of making trial borings upon the site of any proposed stratum, and the methods and appliances generally adopted for making such borings. He then referred to the different strata, which necessitated special foundations for each particular condition, and gave instances of the various forms of foundations on rock, firm and soft ground, describing the plans adopted for preparing rock surfaces, the construction of sumps, and the timbering of the trenches. Foundations of concrete blocks, concrete in *situ* and in bags, piles and cofferdams, pneumatic and other processes of mining were fully described.

The Isle of Man Steam Packet Company.—The directors of this company have contracted with the Fairfield Shipbuilding company for the construction of a new twin-screw steamer with triple-expansion engines, which is to be ready for the next season. The returns for last year show an increase of £16,987 over those of the previous year, the increased expenditure being £9,166, the increase in the number of passengers from Liverpool and Fleetwood being 14,420. The directors at the last meeting decided to recommend the payment of a dividend of 5 per cent., leaving a balance of £2,503 to be carried forward.

The Navigation of the Ribble.—At a meeting of the Navigation Commissioners on the 13th inst., the scheme of the Southport Corporation was explained by Mr. Vernon Harcourt. In order to provide a fixed waterway from Preston to the sea, he suggested that one of the existing training walls from Preston to Lytham should be continued towards the sea, and that a south-western channel should be made to a certain point on the foreshore of Southport. This scheme was opposed by the Preston Corporation and by others, who were in favour of a channel being made on the northern side of the estuary.

SHEFFIELD, 18th February, 1891.

Coal and Iron Trades.—Business in general continues good, although a number of contracts in hand for South America have been stopped until a settled form of government is established in that part of the world. There is little change in quotations for manufactured iron or steel, but pig iron is much easier, and as it cannot, under present conditions of labour and fuel, be sold at a profit, many of the large makers are stocking their produce. Carriage and waggon tyres are quoted at £10 to £12, locomotive tyres at £12 to £14, and springs at about £10. The P. & O. Company's new steamships, now being built by Messrs. Caird & Co., of Greenock, are to be fitted with steel shafting, the cranks being supplied by Messrs. Vickers, and the straight shafting by Messrs. John Brown & Co., who will also supply their Purves flue for the boilers. These flues have been an entire success. An order for locomotives, given out by the Manchester, Sheffield, and Lincolnshire Railway Company, will probably go to Scotland, although a large portion of the material will be produced in this district. Three of the important steel companies have presented a most satisfactory account to the shareholders. Messrs. Brown, Bayley, & Co. and Messrs. Henry Bessemer & Co. each pay 25 per cent., while Messrs. Vickers, who are spending enormous sums on their ordnance plant, give a most satisfactory account of the year's work.

Fuel.—Fuel of all classes is in active demand, and prices are fully maintained. Manufacturing fuel is increasing in price, and users are complaining of its being inadequately screened and cleaned from dirt.

Electric Lighting.—The Sheffield Electric Light and Power Company are building new premises in order to augment their engines and dynamos. A portion of the premises will be utilised for a new switch room, which the increasing business of the Telephone Company has rendered necessary.—The Westinghouse Company have declined to proceed with the installation of the electric light at Barnsley. The company were to have put down the plant and worked it for three months before receiving payment. It is probable that some satisfactory arrangement will be made with the Corporation which will enable the contractors to proceed with the installation.

NORTH STAFFORDSHIRE, 18th February, 1891.

The Iron Trade.—Owing to increased competition prices are suffering. The mills and forges in this district are not working more than about four days per week. Of the thirty-nine furnaces built, there are now nineteen in blast, as compared with twenty-three twelve months ago. Owing to the high price of raw materials it is impossible to make pig iron at a profit at current rates.

The Pottery Trade.—No settlement has at present been arrived at with regard to the question of wages, and the Arbitration Board is still in abeyance. Manufacturers complain that prices are low and unremunerative, and state that payment of higher wages would hamper them in competition with foreign countries.

BARROW-IN-FURNESS, 18th February, 1891.

Hematite.—There is a very serious outlook in the hematite pig iron trade this week. Trade has largely fallen off, and holders of stocks are underselling makers by 3s. a ton, who are thus shut out of the market. The production has been lessened, with a view to reducing stocks. They stood a year ago at 380,000 tons, and, although they have been reduced to 213,000 tons, they still depress the price of metal below its cost when trade is bad. Makers are asking 53s. per ton net f.o.b. for Bessemer mixed numbers, while warrants are changing hands at 50s. There are forty-two furnaces in blast out of seventy-six, compared with fifty at the beginning of the year.

Steel.—Difficulties with workmen will probably lead to the closing of some of the large works in the northern part of the district, where makers have a deficiency of orders, especially in the Bessemer department. If the difficulty cannot be overcome, 1,400 men will be thrown out of work in a week. Heavy rails are still quoted at £4 15s. per ton, light sections at £6, and colliery at £7.—The Moss Bay Hematite Iron and Steel Company, Limited, have recommenced in the steel rail mill department, after a stoppage of ten weeks. The company are engaged upon a German steel rail contract of about 6,000 tons. Both ends of the rails are being planed. Their four blast furnaces are shut down. Messrs. C. Cammell & Co. are working short time. On the 14th inst. the workmen at the West Cumberland Hematite Iron and Steel Company, Limited, received notice to cease work in a fortnight. This is thought to be preparatory to some rearrangements in wages and working hours. The Maryport Hematite Iron and Steel Company, Limited, have erected one of "the Luhrig Company's" coal washers, and are working a blast furnace, using only their own coke, instead of mixing it with East Coast cokes as hitherto.

Shipping.—The shipping returns still show depression. The total shipments of iron this week from West Coast ports amounted to 16,095 tons, compared with 21,939 tons in the corresponding week of last year, a decrease of 5,844 tons. The total shipments now amount to 99,732 tons, compared with 117,975 tons in the corresponding period of last year, a decrease of 18,243 tons.

"Propping" Plant for Mines.—The faulty and insufficient propping and timbering of working shafts and roofs in underground works such as mines, tunnels, &c., and the consequent collapsing of the roofs and sides of such shafts is largely responsible for a number of deaths greatly in excess of those from explosions. Government inspectors have from time to time called attention to the want of care exercised and the methods employed in the staying of these underground shafts. With a view to remedying the existing defective appliances, Mr. W. Wilson Barnes, of Harrington, Cumberland, utilises instead of timber, as heretofore almost exclusively used, iron and steel rail "ends," defective rails, &c., which have been discarded for railway purposes. It will be readily understood that such material will be safer than timber, and will adapt itself to a number of requirements, such as propping and supporting roofs, walls, &c. The inventor claims that in the majority of uses the cost will be less than the cost of timber, with much greater durability.

MIDDLESBROUGH, 18th February, 1891.

Pig Iron.—The market is firmer, and a more hopeful tone prevails. There was a large and animated attendance on 'Change yesterday, and inquiries were more numerous. The minimum price quoted by merchants for No. 3 G.M.B. was 42s., but many held out for 42s. 3d. Warrants were quoted by buyers at 41s. 10½d. cash prompt, 42s. a month; sellers, 1½d. more. In hematite, East Coast brands are 54s. per ton f.o.b. for mixed numbers; maker's iron, West Coast, buyers, 50s. 7d. cash, 50s. 9d. a month; sellers, 1d. more. The stock in Connal's store on the 16th inst. stood at 123,811 tons, being 503 tons more than on the 31st January.

Shipments of Pig Iron.—These have improved very much this month, chiefly owing to the increased shipments to Scotland. Up to the 16th inst. the shipments of pig iron amounted to 41,036 tons, against 17,458 tons to the 16th of last month, and 25,074 tons to the 16th February last year. The shipments to Scotland were 22,475 tons, against 8,130 tons for the corresponding period of last year. Shipments for abroad have also increased.

Manufactured Iron and Steel.—These are much the same as last week, with perhaps more inquiry. Iron ship plates are £5 15s.; angles, £5 12s. 6d.; bars, £5 15s.; steel ship plates, £6; angles, £6 5s.; rails (heavy), £4 17s. 6d. per ton f.o.t. at works, less the usual discount.

Natural Gas.—A discovery has been made on the land of the Tees Salt Company. Whilst boring for salt an outburst of natural gas occurred at a depth of 780ft., which, becoming ignited, shot up into a flame of some 40ft. in height. It is conjectured that there is more underneath, but the quantity is at present unknown. It will add to the desire of many who are working the salt bed to bore underneath it.

SUNDERLAND, 18th February, 1891.

The Shipping and Coal Trade.—There is no improvement to report in the freight market, and the number of steamships laid up does not decrease. The local coal trade continues to be partially paralysed by the continuance of the strike. Last week the coal shipments only reached 57,374 tons, a decrease of 5,984 tons as compared with the previous week; 37,364 tons went coastwise and 20,010 tons to foreign ports. The remaining exports were 705 tons of coke and 900 tons of pitch.

Shipbuilding.—Steady progress is being made with the work in hand, but new contracts are scarce. The Marquis of Londonderry is having two new screw colliers constructed, which will be of steel and fitted with triple-expansion engines. One of the orders has been obtained by Sir William Gray & Co., Limited, West Hartlepool, and the other by a firm on the River Wear. Some heavy repairing work is being done. Mason's patent skylights and sidelights continue in demand. Messrs. Short Bros., Pallion, are fitting six of the skylights and a number of sidelights to a steamer for West Hartlepool owners.

The Shipping Federation.—Notwithstanding all rumours to the contrary, the Shipping Federation continues to do good work. During the first nine weeks of its active operations here it shipped 295 men enrolled on its books, who have formed crews for a large number of steamships, along with 113 men not members of the Federation.

A Historical Vessel.—The steamship "Bergen," now being fitted with triple-expansion engines, and new steel boilers, of 160lb. working pressure, may fairly be styled a historical vessel. When built, twenty-three years ago, the engines fitted were of the "trunk" type, and the boilers of 30lb. working pressure; some years ago compound engines replaced the original ones, and boilers of 70lb. working pressure were supplied. Perhaps the new engines will, in their turn, be "converted" or replaced by quadruple-expansion engines.

The River Wear Commissioners and the Coal Trade.—The annual returns of the River Wear Commissioners would have been most satisfactory if there had not been a diminution in the coal shipments, due to the lessened output of local collieries, the result of higher wages, and to the stoppage of collieries by disputes. 3,740,330 tons were shipped in the year ending December 31st, 1890, a decrease of 382,179 tons as compared with the previous year. The Monkwearmouth Colliery strike accounts for 131,000 tons, and although there was no cessation of work the output of Rhyope Colliery shows a falling off of 60,000 tons. In similar instances the decrease is at least as great, and at all the local collieries there have been decreased outputs. The total income for the year amounts to £128,240 19s. 10d., or £6,193 14s. 10d. less than in the year 1889. The principal shipments, in addition to coal, were 7,822 tons of bottles and glass, 20,758 tons of iron, 33,641 tons of patent fuel, 7,202 tons of cement, and 15,592 tons of lime.

The Paper Trade.—There is much activity in all the local paper manufactories, more especially at the Ford and Hendon Paper Works. Messrs. Chapman's patent apparatus for recovering soda ash from the black liquor, supplied by the makers, Messrs. Fawcett, Preston, & Co., Limited, Liverpool, continues to give as good results as when first fitted. It evaporates 37 tons of water per ton of coal, or 10¼ cwt. per ton of ash recovered.

Electric Lighting.—At a meeting of the County Council, on the 16th inst., it was decided to make application to the Board of Trade, under the Electric Lighting Acts of 1882 and 1888, for supplying electric light.

NEWCASTLE, 18th February, 1891.

The Coal Trade.—The demand for steam coals continues satisfactory, and prices are well maintained. For bunker coals, however, there is very little inquiry, and as the consumption of gas and household coals has, during the past fortnight, largely decreased, the prices of these qualities tend to recede. Nearly all the Northumberland pits, however, are working full time, and as the colliery proprietors have many important forward contracts, steady work is likely to be maintained. The shipments of coal and coke at Tyne Dock during the week ending the 14th inst. amounted to 111,798 tons, being an increase as compared with the shipments for the corresponding week last year of 8,669 tons.

Shipbuilding.—Inquiries for new tonnage are still very scarce, although builders are offering lower quotations. While so many steamers, however, are laid up through want of employment speculative building is likely to diminish, and it is to be feared that a serious dearth of employment will soon be felt at the yards. In a few cases a marked slackness is already apparent, and in view of the fact that the supply of tonnage is greatly in excess of present needs, it seems probable that, excepting at those establishments where Government contracts are in progress, the slackness will in a short time become general.

Engineering.—The question raised some time ago by local members of the Amalgamated Engineers' Society, regarding the placing of further restrictions on the working of overtime, is not yet settled. The engineers' committee are now reconsidering the question, and a modified proposal will shortly be submitted to the employers. In the marine engineering establishments business is still very active, and locomotive factories also have a fair supply of work. Messrs. John Abbott & Co.'s brass finishing and boilermaking departments are very busy, and in the iron foundry connected with their establishments several good contracts are in progress.

Glass Works.—In the flint glass trade business is still inactive, and in some establishments wages disputes are still further limiting the area of production. At the Tyne Plate Glass Works, which for a long period were practically inoperative, business was resumed on a limited scale some months since, and it is expected that in a short time the establishment will again be in full work.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *368, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 399, Strand, London, W.C.*

FRIDAY, 20TH FEBRUARY, 1891.

THE TRAINING OF TECHNICAL TEACHERS.

AT a recent meeting of the Institution of Engineers and Shipbuilders in Scotland, the manager of one of the largest engineering establishments on the Clyde expressed the opinion that the persons most in need of technical education were workshop foremen. The difficulty which he had to meet was where and how to get the instructors. His opinion would not lead us to infer that the foremen are exceptionally unfitted for the due performance of their work, but rather that technical education was not so much needed for the great bulk of the workmen as for those in charge of them. We have very often pointed out that it was much more important to the majority of working men that they should have a good, or, at least, a fair general education, which would enable them to perform their duties as citizens, rather than the mere elements of a few technical subjects, which are of little use from an educational point of view, and which they have few opportunities of applying. In fact, we have little faith in what is usually called technical education by itself in any department of life. Moreover, we have been told by engineers and manufacturers that they do not care for the present system of technical education, which, although it enables the students to pass examinations with facility, seems to deprive them of all originality. Their experience had shown that a healthy, well-educated youth from a country school, almost entirely ignorant of technical training, very soon develops into a more useful man than the town-bred apprentice, whose brain has been narrowed by an unnatural system, which is supposed to be specially fitted to the industrial wants of the present times.

The difficulty stated in the opinion we have quoted, as to where and how to get proper instructors, is one which has never been faced by those in charge of technical education. Too often the men who act as teachers and professors in technical institutions have simply drifted into their work without any special preparation as teachers, and with a very limited experience of practical work. The results have, therefore, been of a most unsatisfactory nature from an educational point of view. Unfortunately, the greatest failures have too often the appearance of success. A man who has passed with difficulty a qualifying examination may, in many cases, by a careful study of the idiosyncrasies of examiners and a judicious investment in old examination papers, be able to make a greater show as regards passes, grants, and even scholarships and exhibitions, than one who tries really to educate his pupils. The teacher whose training has been chiefly in the workshop or manufactory, and who has picked up his theory in an unsystematic way, is too often limited by his own narrow experience, and fails to give a systematic view of the subjects under consideration. On the other hand, the man who is only a university graduate often lectures to students on subjects which they cannot understand, or he enlarges on some theories of his own, which are useful neither from an educational nor a practical point of view. All this proves that discussions about technical education are largely in vain unless they lead to arrangements which give a good supply of well-trained teachers. We must always remember that there are two very distinct classes of minds. One of these shows a leaning towards the practical aspects of affairs, and the other towards the theoretical. We cannot expect successful engineers, who are engrossed in business, to pay much attention to education, or to become teachers, unless they have retired from active work. Our educational institutions might, however, keep themselves more in touch with the advances of the practical applications of science if they occasionally invited well-known men to lecture to their students. This is done to a considerable extent in America, and with the very best results. A few years ago the Institution of Civil Engineers had two such courses of lectures, and the high quality of these showed that there were to be found in this country men who were able to combine eminence in practical work with the ability to make a clear exposition of its principles. The main body of the teaching, however, must be done by men who have adopted teaching as a profession. These teachers should have had a certain amount of practical experience each in his own special department, and they ought to have opportunities of keeping themselves acquainted with the most recent advances by visiting from time to time the best workshops and manufactories in their neighbourhood. There ought, moreover, to be associated with them in the management of their classes a committee of the best men in their district, who would keep them in touch with the requirements of the students. This arrangement is found to be of the greatest advantage to all parties.

Some more systematic method of selecting and training teachers is greatly needed. We ought, if possible, to exclude all those who have no faculty for imparting their knowledge. This should be done at an early stage of the future teacher's career, but we are afraid that it must in the meantime be left to the results of what will be often a very bitter experience. We would impress upon all who have the making of appointments the importance of inquiring, not only into the abilities of the candidates as displayed in their college and other examinations, but also as to their possession of the somewhat rare gift of teaching. We should imagine that the best way of training teachers would be to keep them at a good school till they were 16 or 17 years of age, and thus enable them to study the elements of the subjects which were likely to chiefly engage their attention in the future. They should not be called upon to specialise at this age, since a good general education is likely to be of more use to them than a narrow technical one. On leaving school they ought to proceed to a workshop or manufactory for at least three years, attending evening classes in the meantime. The experience gained in that time will generally be sufficient to warrant a decision on the point as to whether they are more fitted for the workshop or the lecture room. There ought to be a certain number of bursaries and scholarships for assisting the best students among the working classes, but nothing should be done which would tempt large numbers into a career for which they are unfitted. It must be admitted that the tendency of improved education is not so much to enable men to do their present duty in a more efficient manner, as to excite hopes in them of attaining a higher sphere of work.

Digitized by Google

Two or three years' attendance at the day classes of a technical college or a university should fit the student for the position of assistant to a professor, and his future then depends chiefly on his own abilities and perseverance. The training given by our colleges and universities has improved very much during recent years. The old lecturing style has given place to a great extent to work in laboratories and drawing offices, but there is still room for improvement. The lecture room, the drawing office, and the laboratory should be looked upon as forming an essential unity in each department, and the most important work should be done in the two latter. The principles which are expounded in the lecture room should be illustrated in the drawing office, and afterwards investigated in the laboratory, and frequent visits should be made to the engineering works in the neighbourhood. Such a training would turn out men who were well qualified to instruct their students in the theory of their work, and who would at the same time be able to guide them in many points regarding practice. Technical education is not, however, intended to supplant practical training in the workshop or manufactory, but only to supplement it, and students who have studied under such men as we have indicated would generally be found to be apt at their work.

The question as to whether there ought to be central institutions for the training of teachers in technical subjects has been often discussed. We have no hesitation in saying that it would be for the interests of education if the local colleges and universities were developed in this direction, in each case, of course, with a due regard to economy and the requirements of the district. The existence of one or two central institutions for teachers of technical subjects might lead to a stereotyped method of teaching, and thus cause a great deterioration in the quality of the education and of the men. Variety is as much needed in education as in anything else, and it is only by having institutions of different types that we can expect to have such conditions as will encourage originality. We do not wish it to be inferred that for special departments of investigation for which there is only a very limited demand it is not often an advantage to concentrate all efforts on a few places. We simply wish to avoid any system of centralisation which would lead to a dead level of uniformity.

A JAPANESE VIEW OF NEW JAPAN.

We have several times directed the attention of our readers to the question of treaty revision with Japan, in so far as it is connected with the development of trade and industry, and have not hesitated in expressing the opinion that the present state of affairs is a grave injustice to Japan and an injury to the foreign trade of this country. We have also pointed out that, on account of the unreasonable delay which has taken place, the problems connected with the matter have been very much complicated, for the Foreign Powers have no longer simply to deal with the members of a practically autocratic Government, but with a representative Government, which is criticised by a widely extended public press. It is not often that people in this part of the world have an opportunity of obtaining the opinions of an educated Japanese—at least, in a direct manner—on questions referring to the relations of Japan and foreign countries, and when such an opportunity does occur it ought to be taken advantage of by all who are studying the questions involved.

Such an opportunity is given in the current number of the *Nineteenth Century*, in which a Japanese view of New Japan is given by Mr. Daigoro Goh, some of whose opinions we may note, in so far as they relate to treaty revision and the development of trade and industry. Mr. Goh writes with a certain dash of Eastern style, and evidently under a keen sense of feeling, which may tend to give his readers the impression that he is not a correct exponent of average Japanese opinion. He is smarting under what he considers the injustice done to his country at a meeting of foreign residents held in Yokohama for the purpose of considering the question of treaty revision, which he says so aroused him as to cause a determination to take up his pen on behalf of his country. Mr. Goh gives a short sketch of the changes which have taken place in Japan since the existing treaties were signed in 1858, when Japan was an obscure country, almost unknown to the rest of the world, and her government an obsolete feudal system. Man or horse supplied the place of the mail train, telegraph, and telephone; and the back of beast or the shoulder of man was her only means of land transport. Her people went about the streets armed with swords, and no signs of Western civilisation could be detected in her social or political life. This state of things has so entirely ceased that we may regard them as ancient history. The name of Yedo has disappeared, while that of the Tycoon, at that time the absolute ruler of Japan, by whom the treaties were ratified, has been almost entirely lost in oblivion. Even the coins mentioned in the treaties are no longer in circulation, and the whole style of expression is so strange to the present generation that there is great difficulty in understanding it. In brief, Mr. Goh says, the present treaties were signed when Japan was in a state of ignorance and inexperience with regard to international intercourse, and hence they are quite unsuited to the requirements of the present times.

The chief points agreed upon in these treaties were that the Japanese Government were to open seven ports as markets for foreign trade, to grant concessions for foreign settlements in which foreigners might reside and trade, and round which they might make excursions within a distance of about twenty-four miles. All foreigners were to be subject to their own consular jurisdiction, and to be quite independent of Japanese courts and laws. Lastly, the custom duties were fixed at 5 per cent. *ad valorem*. By these provisions both the judicial and the tariff autonomy is fettered to a great extent, and the national rights of the country infringed, and these prove very sore points to the younger generation of Japanese. The treaty contains a clause by which both parties had a right to demand a revision of the document at the end of fourteen years—that is, in 1872. Ever since that date the question has been under discussion, and if ever its history comes to be written it will form one of the most curious chapters in the history of diplomacy, and an illustration of laborious trifling on the part of the representatives of the Foreign Powers which is without a parallel. Thirty-two years have passed, and great changes have in the interval taken place in Japan. Her feudal system has passed through a bureaucracy to a constitutional Government, and this by a natural process of evolution, and without those struggles which have usually accompanied such changes in Europe. Her army and navy have been entirely remodelled, her laws and judicial system reconstructed, and education in every department has been largely developed according to Western ideas. These changes have had a most remarkable effect on the industrial and commercial development of the country. The postal and telegraph systems are as good in Japan as in Great Britain, railways are being rapidly extended, the mercantile marine has assumed large proportions, harbours and docks have been constructed, and the lighthouse system is very complete. Her foreign trade has doubled within the last ten years, and quadrupled during the last twenty years, whilst the growth of commercial and industrial enterprise has been something wonderful.

The Japanese are a proud and sensitive people, and the restrictions of the treaties have been very galling to them. The extensive improvements and reforms, and the various public works which have been inaugurated within the last few years, have naturally entailed the expenditure of vast sums of money, to obtain which heavy taxes had to be levied upon the land and other estates, as the treaties prevented an increase in the tariff dues. But the most galling of all was the question of extra-territorial jurisdiction, which the Japanese assert has been much more than a sentimental grievance, for they think that the aliens take an unfair advantage of the protection extended to them by the consular courts to annoy and defy the Japanese people. The subject has caused great excitement in Japan, and has sadly embarrassed the Government. Within the past three years the Cabinet has resigned twice, and two Ministers of Foreign Affairs have been obliged to retire from office, and it was found necessary in order to restrain political agitators to pass a "Peace Preservation Act." These facts are mentioned for the purpose of showing how much the subject has become involved with questions of party and personal politics. The complication has been increased by the recent action of the foreign residents in Yokohama, and it is this which has raised the excitement of Mr. Goh, and compelled him to speak out on the subject. A meeting was held a few months ago, at which two resolutions were unanimously passed, the first protesting against the idea of giving up the right of extra-territorial jurisdiction, and the second against the alteration of the conditions of their tenure of land without their consent. Nothing was said about the tariff, because we suppose no valid arguments could be brought forward to support the present arrangements, but the promoters of the meeting must have known that the Japanese Government would not consent to the consideration of the one without at the same time dealing with the other, so that the resolutions carry more than appears in them to those who are not acquainted with all the facts of the case. They were telegraphed to London, and from thence were sent to all the chief Chambers of Commerce in this country and in Europe and America, and will no doubt come up for discussion in due time. In the meantime, the Chambers of Commerce are collecting information with regard to the question. We understand that a request has been made to the British Foreign Office for accurate information as to the state of the treaty negotiations, which information the authorities have declined to make public for the present. Perhaps they are wise in this for the sake of their own reputation. The proposals which have been made at various times by the Japanese Government have always seemed to us to be very reasonable, and such as might be agreed to without difficulty, especially if there were a period of years fixed during which tentative arrangements would be made and changes gradually carried out. The longer the question is postponed the more difficult will be the solution, for in the present state of public opinion in Japan no Government dare propose any measure which is not fairly satisfactory from a Japanese point of view. It may be taken for granted that the Japanese demands will increase as time goes on. The question of the rights of the holders of land in the foreign concessions is one which admits of easy adjustment, and it is difficult to understand why it was raised. The British Government does not ask the consent either of landlords or tenants when legislating on the land question, although it endeavours to meet the just claims of all parties. The supreme consideration being the welfare of the country.

We cannot enter into either the political or judicial questions involved, but before concluding we will consider shortly how their settlement affects the trade and industry of this country and Japan. Twenty years ago the foreign trade amounted to $33,692,000, ten years later it had increased to $61,128,000, and in another ten years—namely, in 1889—it had exceeded $136,164,000, of which more than one-fourth represents trade with Britain. All this has been done within very restricted limits, for although there are nominally seven treaty ports, practically there are only four in use. There are none of the facilities for extending trade by the introduction of foreign capital or the encouragement of enterprise on the part of foreigners in every department of industry and commerce. And the revision of treaties is the simple and only means whereby the obstacles may be removed. Mr. Goh has compiled tables which show that the proportion of Japanese trade formerly monopolised by England is steadily declining, while that of Germany is rapidly increasing, a fact which he attributes chiefly to the feeling prevailing among Japanese people. We trust that the British Government will at once give attention to this question, not only in the interests of our own trade and commerce, but also in that of justice to the Japanese nation.

TECHNICAL EDUCATION.

The grant of £743,000 under the Local Taxation Act, 1890, for the purpose of increasing the sum available for carrying out the provisions of the Technical Instruction Act, 1889, has already had important consequences. The considerable advance that has been made since the grant became payable is narrated in detail in the "Reports of Committees of County Councils, and Other Schemes and Proposals for the Utilisation of the New Fund, &c.," just issued by the National Association for the Promotion of Technical and Secondary Education. A year ago, only four local authorities had taken advantage of the Technical Instruction Act of 1889; now forty-two local authorities and several counties and county boroughs have adopted the Act, while many of the County Councils in Wales have appointed their joint committees on intermediate education to be committees under the Technical Instruction Act. Attention is called in the Reports to the presumption of permanence afforded by the circumstances under which the annual grant was made available, and by the subsequent statement of the Chancellor of the Exchequer in reply to a question asked by the Marquis of Hartington. Among the reports and schemes drawn up by representatives of institutions for technical education, with the object of increasing the means at their disposal by securing grants from the City and County Councils, are reports from a conference at Liverpool, from a committee at Newcastle, from University College, Bangor, with a scheme for providing a system of agricultural education for North Wales, and from the Joint Education Committee of Carnarvonshire. The Reports conclude with a statement upon the position of secondary education in Scotland, by Professor Laurie, of Edinburgh University

RAILWAY SERVANTS' HOURS OF DUTY.

At a meeting of the Balloon Society, held on the 13th inst., a paper on the above subject, by Mr. Chas. Jardine, C.E., was read. The author of the paper stated that, having been engaged for over thirty years in railway pursuits in nearly all parts of the world, involving the question of railway labour, he was induced to prepare the paper read. After referring at some length to the motion introduced into the House of Commons by Mr. Channing, and the amendment to the same by the President of the Board of Trade, which was carried by the small majority of 17, he said the plea of the President of the Board of Trade for supporting the companies was that he did not find any desire on the part of the men to forego the pleasure of extra payment for overtime. A return had just been issued in pursuance of section 4 of the Regulation of Railways Act, 1889, showing the number of certain classes of weekly paid servants in the United Kingdom who, during the months of September, 1889, and March, 1890, had worked more than twelve hours at a time, or who, having been on duty for twelve hours, were allowed to resume work with less than eight hours' rest. It was shown that some companies had passed stringent rules as a protection against long hours, and the servants had actually broken them, showing a desire on their part to have no restriction on their working hours and to earn more money by overtime. He considered the code of regulations on the London and North-Western Railway was only a sample of some of the rules in force on some of the principal railways, and overtime was excluded from the time tables for servants of all grades. In conclusion, the author gave it as his opinion that it was absolutely impossible to avoid long hours on certain occasions, and in many cases it was not to the interest of the men that they should be abolished. He hoped that the Select Committee to be appointed to inquire into the question of restricting by law the hours of railway servants would inquire into the management of railways in foreign countries.

Letters to the Editor.

THE PRESENT POSITION OF THE ALKALI TRADE.

To the Editor of "Industries."

Sir,—I have watched with considerable interest the development of the negotiations for the formation of the Chemical Union, not only as a curious study in the evolution of industry, but also from the point of view of its effect on the public. I must confess frankly that all this system of trusts, syndicates, unions, and amalgamations of railways and other concerns seem to point to a state of affairs in which all the industrial interests of the country will be under the control of a comparatively small number of men, and the question for the public to consider is, How are their interests to be represented? Some one has said that large industrial unions, plus a policeman to prevent them from enriching themselves too much at the expense of the public, is Socialism, and there can be no doubt there is some force in the definition. There cannot, also, be the slightest doubt but that such industrial unions lead to economy, by the avoidance of competition, the reduction of the cost of transit and expenses of management, and generally by increased efficiency in the manufactories. But who is to be the judge of the prices of the finished material—who is to keep them at such moderate limits as will yield a fair return? For the question arises, "Return" on what? It is a comparatively simple matter to make the returns appear small by watering the stock to a sufficient amount, and, no doubt, the original shareholders of the alkali works would be content with a very moderate return on their original capital, for, as you point out, and support by evidence which cannot be doubted, the struggle between the old and the newer process of alkali manufacture is no longer doubtful.

Practically, the whole of the registered capital of the Chemical Union is absorbed in the mere purchase of works and patent rights, and it proposes to start operations heavily in debt, so that it has not the means for performing what you have shown to be necessary for its success, from a financial point of view—that is, completely revolutionising its means of production—in fact, by transforming its old plant and remodelling its manufactures on the lines of modern progress. The Union may appear to have some success at the beginning of its operations, but it does not require the gift of prophecy to see that its ultimate break-up and defeat as a dividend-making concern is pretty certain. If the public find themselves left with the alkali baby to hold they will have themselves to blame, for they have received sufficient warning from all independent authorities who have investigated the matter.

Yours, &c.,
Alkali.

Glasgow, 14th February, 1891.

REVISION OF THE ORDNANCE SURVEY.

To the Editor of "Industries."

Sir,—In your issue of the 30th ult. you have a short article on the Revision of the Ordnance Survey, in which you refer to my paper read at the Leeds meeting of the British Association. I shall be glad if you can give me space for a few remarks on your article, and in explanation of the objects of my paper.

In the first place, I cannot agree with you that the arrangements for the supply to the public of the maps "are now fairly good." The present system is the worst that has been adopted since the institution of the survey; although, in my explanation of the various reasons why the productions of the survey are so little utilised, I did not give it the first place, yet it is one of great importance. Engineers and other professional men who "know the ropes" may not experience much difficulty in getting what they want, but to the generality of citizens the Ordnance Survey is a mystery.

There is a vague idea that somewhere or other there exists a quasi military department engaged in the production of maps, but of the extent, variety, and value of this great national work the general public knows little or nothing. For this state of affairs the Government and the Department must share the blame, for no real attempt to popularise the work has ever been made by either. If the public is ignorant of the work of the national survey, the Government is equally dead to modern ideas and necessities. Although the map-using portion of the community is increasing with the rapid advances making in those branches of knowledge for which good maps are essential, the progress of cartographical science in England has certainly not kept pace with these requirements. For certain special purposes and for particular classes, who use maps in their professional avocations, the Government has done excellent work, but popular services it has never attempted to render, and all efforts to arouse the authorities to a sense of their deficiencies in this respect have hitherto been unavailing. The neglect of the popular side of the business has caused the survey to be looked upon as a work intended chiefly, if not solely, for the limited class referred to. As I said at Leeds: "The various productions might be much more largely utilised if the arrangements for the sale and distribution were put on a reasonable basis, and measures taken to let the inhabitants of various localities know something of the state of the publications in their own districts."

The question of the state of the survey has not dropped, as you surmise. The British Association appointed a Committee to carry out the resolution adopted at the Leeds meeting. I attended a meeting of this Committee on Wednesday last, and I trust the Council of the Association will be able to make representations to Government which may lead to some, at least, of the defects being remedied. A thorough revision is the most pressing necessity, and for this work a permanent department must be created.

I confess that I fear little improvement will be made until public opinion is better instructed. Nothing is more difficult to move than a Department which has got into a groove. It is from public interest alone that the impulse can come to move Parliament and the Government to make the necessary provision without which the existing deficiencies in the work of the survey cannot be remedied. The Press, and especially the technical Press, can render valuable assistance if it will take the matter up in the spirit in which you have done.

Yours, &c.,
Henry T. Crook.

9, Albert Square, Manchester,
12th February, 1891.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—I think the modification of Mr. Thwaite's original plans, as suggested by your correspondent, Mr. James Armer, will be necessary before the scheme has a chance of commending itself to financiers. The idea of making gas at the pit mouth and then piping it to London is no new thing, but the expense of suitable mains, the leakage and condensation, and the enormous difference in the value of the residuals at the pit, where they are not wanted, and in London, where they are, would go far to neutralise the advantage of cheap coal. Also what compensation would have to be made to existing vested interests? The nominal capital of the Chartered Gas Company alone is about ten millions sterling.

When the public have got rid of a lot of foolish and antiquated ideas about the danger to health of burning gas as fuel, the change from gas light to electric light, and from raw coal fires to gaseous fuel fires will be brought about quite rapidly enough. Then we shall get rid of fog and smoke. If Mr. Thwaite will continue his crusade against the filthy coal fire, and devote his energies to proving that a gas fire is as cheap and infinitely more convenient and cleanly, the battle will be won. I fear he will have to abandon the pipe-line and hot-air-from-the-basement parts of his scheme.

Yours, &c.,
F. G. D.

London, 13th February, 1891.

To the Editor of "Industries."

Sir,—One feature that would follow the carrying out of Mr. Thwaite's project would be the removal of that swindling fraternity—the mushroom coal merchant, described in a favourite non-technical weekly contemporary. It appears that although the London County Council have framed bye-laws to prevent the poor people from being swindled, they are comparatively useless, and a great part of the London poorer population pay from 30s. to 40s. a ton for rubbish composed of coal and dirt. It would be as well if the London County Council dropped, for the present, their water supply scheme, and instead undertook the supply of gas for heating. Nearly all the northern towns obtain a splendid profit from the gas departments which they own, so much so that a great part of the sanitary improvements are carried out with the surplus profit, which for London would be enormous, as Mr. Thwaite's calculations show.

Yours, &c.,
D. H. N.

Manchester, 17th February, 1891.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

To the Editor of "Industries."

Sir,—It appears to me that perhaps the most conclusive manner in which the above question can be answered is by the very simple method of asking what the meanings of the two words—Engineer and Thermodynamics—are. The best definition, so far as I know, of an engineer, is "one who controls the forces of nature so that they may administer to the wants of man." Of all these forces the most potent is heat, and thermodynamics is the science which teaches us the laws governing the transference of heat into work.

Now let us put our question thus: Is the study of the laws governing the transference of heat into work of use to a man whose chief business in life is to effect this transference in the most efficient manner possible? Put in this way, "Student" will probably see that there can be but one answer to the question, and that the affirmative.

So much for the question in its largest aspect, but probably "Student" would prefer a little more detailed answer; also there are some points worth noticing with regard to one source of this discussion—viz., the review in the *Engineer* of Professor Cotterill's book, on which something of interest to all students may be said. The great aim of an engineer is to make a set of engines which shall be as efficient as possible, bearing in mind first cost, amount of coal consumed, cost of repairs, &c., the great aim being, as a rule, to get as much work done as possible for as little money as possible. In order to be able to do this, he must be able to calculate with accuracy the efficiency of his engine, and also to determine what gain of efficiency he is likely to make by any proposed alteration, and hence to determine whether such alteration would pay, for in a general way it is no good gaining, say, 5 per cent. in coal at a cost of 100 per cent. in first cost, although of course there may be cases in which this would be justifiable.

Now, taking for definiteness, a marine steam engine, the best set of engines and boilers is that which drive the ship farthest at a given speed per ton of coal; but if I wish to get a better result, I must first find out where improvement is possible, for I may have a good set of engines with poor boilers, or *vice versâ*. At once, then, we see that we must have a separation between the efficiency of the boiler and that of the engine, or otherwise we might be condemning one for the faults of the other. But a little consideration will show that we must go farther still in our separation, because the engine itself has two separate efficiencies—viz., a thermal efficiency and a mechanical efficiency, the former being the ratio which the work done in the cylinder bears to the heat expended on the steam, and the latter the ratio of the work done in propelling the ship to that done by the steam in the cylinder. The boiler efficiency depends on the size and arrangement of the boiler and its furnaces, flues, &c., and the last mentioned on the mechanical details of the engines and the proportions of the screw, and neither requires thermodynamical knowledge; but there is left now for determination steam pressure; type of engine, simple, compound, or triple; actual size of engine, proportions of cylinders, and speed of piston, these being the things which determine the thermal efficiency, and which are plainly of the utmost importance, and it is for the study of these questions that a knowledge of thermodynamics is now an absolute necessity. Without this knowledge, although one engine can be recognised, as a whole, as superior to another, yet the source of its superiority cannot be determined, nor the amount of gain apportioned, should there be more than one source, and thus only by a long and costly process of trial and error can we tell the proper direction in which progress can be made.

Of course we shall hear to this the usual objection, as stated in the *Engineer*, that the engineers who have brought us to our present state of efficiency were ignorant of the theory of the steam engine; and this is no doubt to a great extent true; but what writers of this type fail to grasp is that these engineers were making the theory, and that the engineers of the present day have to commence where their predecessors left off. The steam engine of twenty or thirty years ago was, in general, such a wasteful machine that almost any alteration was bound to improve it, and an immense margin for gain existed, so that little matters of one or two per cent. were not worth considering.

But now, except perhaps in gas engines, the ones and twos per cent. are nearly all the engineer can look to gain by his different improvements, and to make these small gains he wants a much more intimate acquaintance with his subject than was necessary when the large ones could be obtained. I do not know if the *Engineer* maintains that a knowledge of thermodynamics is not required in the study of gas engines, but I pity the student who may make the attempt to do without it.

This consideration as to the smallness of the margin left for improvements brings us to one of the most important uses of theory of the steam engine as pointed out by Mr. Bodmer—viz, that there is no 90 per cent. margin for improvement. Without thermodynamics it is doubtful whether anyone can really grasp this fact; many engineers agree to accept it, but there is always a hankering after "saving the latent heat," and new inventions regularly crop up directed to this end, meeting sometimes with a reception that shows that many eminent engineers still doubt the second law of thermodynamics: the latest of these is probably fresh in the memory of most of your readers—viz., Yarrow's "Zephyr" launches. I remember the claims for saving the latent heat advanced at the time, and for all I know still believed in, but although no doubt a handy kind of boat altogether, I have not yet heard that they have obtained any increase of economy over steam, and they have certainly not yet overthrown the second law. I do not remember for certain, but have little doubt that the *Engineer* uttered one of its usual triumphant songs on the downfall of theory at the time.

Mr. Bodmer speaks of the saving of fruitless labour, and a most instructive example, which "Student," if young, may not have heard of, is the case of the Marchant engine. Mr. Marchant invented an engine with a peculiar arrangement of pumps, by which the latent heat was pumped back into the boiler, and thus a saving of 90 per cent. effected, and this statement was allowed to appear on the walls of the Inventions Exhibition. Mr. Marchant produced tests to prove his statements, so far as I am competent to judge, with perfect honesty and belief in their genuineness; a company was formed to manufacture the engine, but, directly it was subjected to independent testing, the whole fabric collapsed, as everyone with a knowledge of thermodynamics knew must be the case, and the inventor, after a short struggle, was obliged to confess himself beaten, and has lapsed into obscurity, with, I believe a life's work wasted, for the want of what a few weeks' study would have supplied.

I am afraid I am trespassing too much on your space, but I should like, in conclusion, to say just a few words, to advise "Student" to look with very great suspicion on any statement as to the teaching of thermodynamics, or any other subject, which may appear in the *Engineer*. That journal, as was well pointed out

Digitized by Google

by Professor Barr, in his introductory lecture to the Yorkshire College in 1888, is the apostle of ignorance, in not only thermodynamics, but every kind of theory, and, judging by its utterances, it lives well up to its principles; thus, when it states that the progress since 1877 has been in direct opposition to the teaching in Professor Cotterill's book, "Student" should, before attaching any value to this statement, first find out if the writer of it knew what the teaching in "Cotterill's Steam Engine" was, and perhaps the following fact may help to give him an idea of what the result of such an inquiry would be. Professor Cotterill's book was published in 1878, and in, I think, 1887, or thereabouts, a not unimportant member of the staff of the *Engineer* actually read a paper before the British Association, on "Some Hitherto Unnoticed Facts in the Theory of Steam," which was nothing more than a few arithmetical calculations which appear at the commencement of Chapter VII. of that book. If it had taken the *Engineer* nine years' study before they reached Chapter VII., it appears not unlikely that they will be a few more years before obtaining a grasp of the teaching of the whole book.

Yours, &c.,
JOHN H. SLADE,
Chief Engineer, R.N.

Portsmouth, 16th February, 1891.

THE TAXATION OF MACHINERY.

TO THE EDITOR OF "INDUSTRIES."

SIR,—May I ask a portion of your valuable space to call the attention of your readers to the Bill for the Exemption of Machinery from Rating which is down for the second reading on Wednesday next, the 25th inst. It is of the utmost importance that a decisive majority should be obtained in the division, and your readers, who are interested in the question, will greatly assist if they will at once write to their respective Parliamentary representatives, urging them to attend and vote in favour of the Bill.

It is very remarkable to find the members for such constituencies as Newcastle and Sunderland opposing the measure.

Yours, &c.,
G. HUMPHREYS DAVIES, Secretary,
National Society for the Exemption of Machinery from Rating.

22, Buckingham Street, Adelphi, London,
18th February, 1891.

THE PHYSICAL SOCIETY.

AT the annual general meeting of this Society, held on the 13th inst., Professor A. W. Reinold, F.R.S., being in the chair, the reports of the Council and Treasurer were read and approved. From the former it appears that there has been a satisfactory increase in the number of members, and in the average attendance at the meetings. The Treasurer's statement shows that the financial condition of the Society is very satisfactory.

The general meeting was afterwards resolved into an ordinary meeting, and a paper on "The Change in the Absorption Spectrum of Cobalt Glass Produced by Heat," by Sir John Conroy, Bart., M.A., was read by Mr. Blakesley. The absorption spectrum of cobalt glass, when cold, consists of three dark bands in the red, yellow, and green, with a considerable amount of absorption between the first two. When a piece is heated to nearly red heat, the absorption between the first two dark bands diminishes, and the band in the red moves towards the least refrangible end of the spectrum, whilst those in the yellow and green retain their position, but become less distinct. During the heating of the glass the intensity of its colour diminishes, and as the glass cools its original colour and absorption spectrum returns. In conclusion, the author states that his observations, and those of Feussner on solutions, show that the absorption spectra of some substances vary with temperature. In solutions, this may be due to formation of different hydrates or to partial dissociation, but in a solid like cobalt glass an actual change in its chemical constitution at a temperature considerably below its fusing point does not seem probable.

In the discussion, Dr. Gladstone said it was generally known that heat affects the colouring power of substances, and that, in solutions, absorption is greater the higher the temperature. Different solvents sometimes produce effects analogous to heat, for cobalt salt dissolved in water and in alcohol give pink and blue solutions respectively, and rise of temperature makes the aqueous solution more blue. He concurred with the author as to the causes of the phenomena in liquids, and that the same explanation would not apply to glass.

Professor S. P. Thompson thought Sir John Conroy's results agreed with the experiments which Mr. Ackroyd showed before the Society some years ago, when he demonstrated that the colours reflected by opaque bodies —such as porcelain, &c.—when heated, tend towards red.

Professor Minchin showed some experiments in illustration of his paper on "Photo-Electricity," read at the previous meeting. In one of these a seleno-aluminium battery, illuminated by the light of a taper, deflected an electrometer needle, thereby actuating a relay and ringing a bell. He afterwards exhibited one of his "impulsion cells" in action, and showed the change from the insensitive to the sensitive state produced by a Hertz oscillator at a distance.

In the discussion, Mr. Tunzelmann said Kalischer and Von Uljanin had worked at the same subject, the former being the first to make experiments on a photo e.m.f. in selenium. His cells were made by winding brass wires on glass tubes and coating them with selenium, which was subsequently annealed. These cells lost their power after some time, and would not respond to feeble lights. By using two wires of different metals, he obtained better results. Fritts, in 1883, used brass and gold plates coated with selenium, and Uljanin employed platinum plates deposited so thin as to be transparent. The latter experimenter found that the e.m.f. was proportional to the square root of the intensity of the light. He also observed that the orange-yellow of the prismatic spectrum produced the greatest effect, whereas the yellow-green and the green rays of the diffraction spectrum gave the maximum e.m.f. Comparing these results with Langley's observations on the energy of the spectrum, it would appear that the e.m.f. bears no relation to the maximum energy falling on the surfaces. Speaking of the cause of the phenomena, he said the electrolytic idea of Von Uljanin seemed inapplicable to Professor Minchin's results, and he inquired whether a mixture of selenium and aluminium would undergo a gradual change by exposure to light.

Dr. Gladstone said such a change, if it occurred, would be very slow, for nearly all difficult chemical reactions take time to complete. The fading of colours was adduced as an instance of slow chemical change produced by light.

Dr. Waller thought the subject might throw light on the changes occurring in the retina, and asked if it was possible to separate thermo-electric and photo-chemical effects.

Dr. Burton said he had suggested that the action of light on the retina was a photo-chemical one some time ago, but hitherto it had been difficult to obtain substances sensitive to any but the blue and violet rays, whereas the eye was most sensitive to green and yellow light. In the photo-electric batteries, however, the e.m.f. may generate a current, and therefore energy, and the important question seemed to be — Where does this energy come from? Is a chemical change precipitated by the action of light, or does a direct conversion of light into electric energy occur?

Professor Minchin, in his reply, said he thought his cells really transformed the incident energy. They were usually kept on open circuit, and there appeared to be no deterioration with time, the only change being a sluggishness in developing their maximum e.m.f.

THE MANCHESTER SHIP CANAL.

I.

SINCE the publication of our former articles (see *Industries*, Vol. IX., page 171), describing the works of this great undertaking, considerable progress has been made with the work throughout the entire length of 34½ miles. The two serious floods which occurred last year, although they stopped a large portion of the works at the time, were not so disastrous as might have been expected; a portion of the flooded work was completed, and the water has been allowed to remain in, and the remainder was very speedily got rid of by effective pumping machinery and other devices. At the last general meeting of the shareholders, held at Manchester, on the 3rd inst., the chairman announced that the company intended to complete the construction of the work themselves, and, as a large amount of money would be locked up in the enormous plant in use—which could not be realised until the completion of the work—it was decided to apply to the Manchester Corporation for financial assistance, and to Parliament for further borrowing powers.

By the courtesy of Mr. Leader Williams we are enabled to give a series of illustrations of the progress of the work since we last described it, the present series showing the state of the work in June, 1890. The works, of course, are now much further advanced; but these views will form a connecting link between those already published and those which we propose publishing at a later date when the work is further advanced.

Fig. 1, on page 180, shows the gantry which was constructed at Ellesmere Port to enable the permanent works to be constructed for confining the canal at this point. This work is one of the most interesting in the whole length, and had to be carried out under great difficulties, for it was necessary to construct a swing bridge and other temporary works, so that the traffic between the docks and the Mersey was not interfered with. The permanent work is now approaching completion.

Fig. 2 shows the work at the Eastham Locks. This is the point where the canal commences, and where it leaves the estuary of the Mersey by means of three locks of different sizes to accommodate the various sizes of ships. The largest lock is 600ft. long between the upper and lower gates, and 80ft. wide; the extra width beyond the 65ft. locks in the remainder of the canal being given to facilitate entrance during stormy weather. The middle lock is 350ft. between the gates, and 50ft. wide below the copings; the outer lock—next the river —being 150ft. long by 30ft. wide. Each of the docks is provided with storm gates in addition to the ordinary ones. There are, in addition, two Stoney sluices, each 20ft. wide. The sluices for emptying and filling the docks are all on the Stoney principle, the culverts being of large capacity to ensure a good scour of the heel posts and of the entrance. The illustration shows the sluiceway in the foreground.

SOME APPLICATIONS OF PHOTOGRAPHY.

ON the 6th inst. an interesting lecture on this subject was delivered at the Royal Institution by Lord Rayleigh, F.R.S. The lecturer, after referring to Mr. Muybridge's photographs of animals in motion taken by means of a movable shutter, said that rapidly occurring phenomena might also be photographed by the exposure of the lens to a flash of magnesium light or to the electrical spark. Neither of these flashes of light was absolutely instantaneous. Their degree of instantaneity might be estimated by means of a wheel with black and white divisions revolving at a great speed. If the flash were of sufficiently short duration, the wheel would appear to be stationary. A series of teeth cut in the edge of the wheel allowed the rapidity of their motion to be calculated by means of a syren. With a flash of magnesium light the wheel appeared of a grey colour, and the flash was shown to last from $\frac{1}{10}$th to $\frac{1}{50}$th of a second. A spark from a Leyden jar, however, made the wheel appear stationary. It had been shown that the duration of the principal part of such a spark was less than $\frac{1}{1500000}$th of a second. Some idea might be formed of such a duration by considering that it was nearly the same fraction of a second as one second is of a year, as a year contains roughly 25,000,000 seconds. Multiple discharges from a Leyden jar might, however, last for $\frac{6}{1000}$ths of a second. In using the spark of a Leyden jar for instantaneous photography, it was better to connect the plates of the machine with the inside coatings of the jars, and photograph the object by a spark taken between the outside parts of the jars. There was thus no high potential, and less chance of losing the effect of the discharge. By means of instantaneous photography, it was seen that a jet of oxygen on passing through water was at once split up into bubbles on its first issuing from the tube. A jet of water, when made to issue into the air from a nozzle of drawn-out glass, was at first cylindrical, and then, becoming swollen or varicose owing to surface tension, was broken up into drops, each drop being connected with the cylinder by a thin ligament before it was separated. The vibrations of a tuning-fork caused the column of water to break into drops at an earlier period. The ligament itself was afterwards formed into one or two drops. Mr. Chichester Bell and Mr. Boys had observed these effects by taking instantaneous photographs of the shadow of the jet. When, however, a jet of any fluid is forced into a vessel containing another fluid the jet becomes sensitive, and is broken up into a series of coils. Under the vibrations of a heavy tuning-fork, the jet becomes unstable nearer the nozzle. Under less pressure, and with regular vibrations, the jet forms a sinuous band, with a horn at the summit of each wave. Such a jet always gives way by becoming sinuous, whereas the jet of water issuing into air gives way by becoming varicose. A soap film might be photographed in the act of breaking, but as this occupied less than $\frac{1}{10}$th of a second, it was more difficult to photograph than jets of liquid. A dry shot was shown to pass through a soap bubble without breaking it, but a shot wetted with alcohol would break the film at once. By means of the dropping of weights suspended from an electromagnet, it was possible to make the breaking of the film and the flash of the spark simultaneous, and thus photograph the film in the act of breaking.

Reviews.

TRAITÉ DE PHYSIQUE INDUSTRIELLE. Par L. Ser, Ingénieur, Professeur à l'Ecole Centrale des Arts et Manufactures. Tom. II., 1re Partie. Paris: G. MASSON, Editeur. 1890.

Some time ago M. Ser published the first part of what was intended to be a very complete treatise on industrial physics, and especially on the production and utilisation of heat. That volume treated of general principles, of furnaces and other receivers of heat, of chimneys, venti-

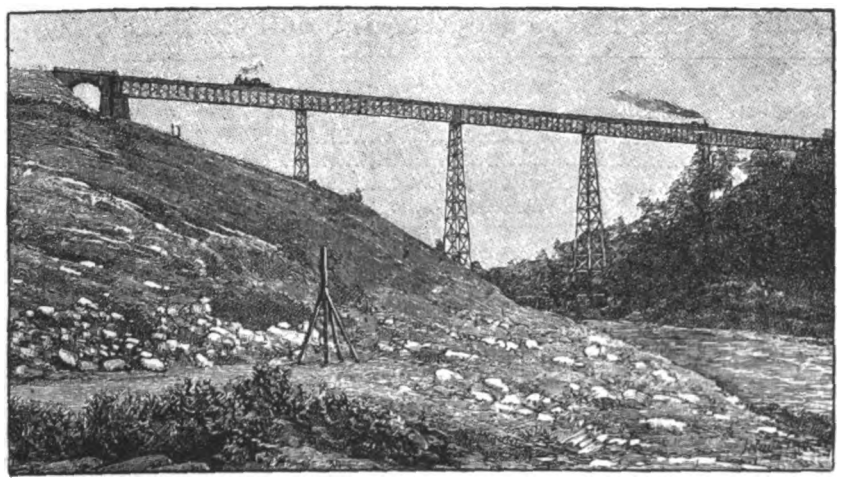

Fig. 1.

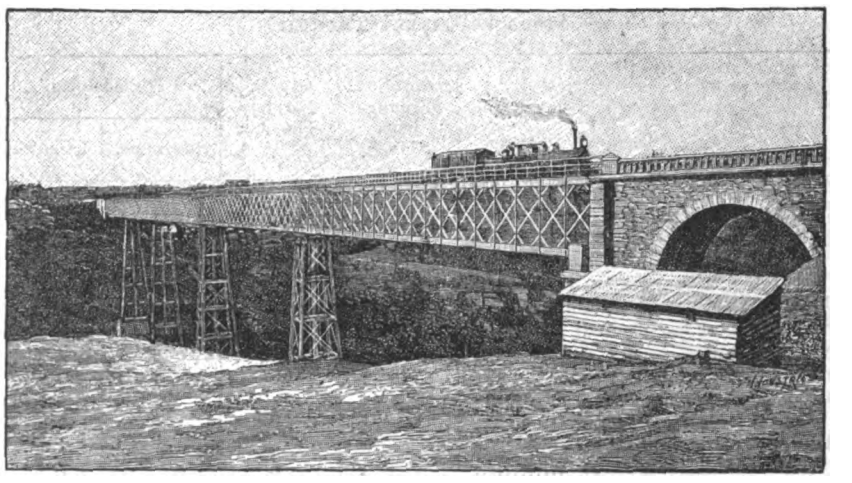

Fig. 2.

lators, &c., and of the theory of thermodynamics. It was one of the most complete of its kind, and supplied the most recent information. Since that work appeared, M. Ser has died prematurely, before he was able to complete the task to which he had set himself. The present volume is the first instalment of the second part of the work, and has been edited by MM. Carette and Herscher from the materials left by M. Ser, and treats of steam boilers, distillation, evaporation, drying, and disinfection. Some years ago, before engineering had received the special developments of the present day, treatises on industrial physics and mechanics were somewhat common, especially in France. At the present time the tendency is to have general treatises on physics and mechanics, and special treatises on the different departments of engineering. Although M. Ser's work will be useful to practical engineers, it is intended primarily for students of technical schools, and for this purpose it is admirably adapted, and forms a most useful introduction to the more practical treatises. After a preliminary *résumé* of the chief laws of heat as applied to vapours, a description is given of varieties of boilers and the apparatus connected with them. Results of experiments, methods of construction and of observation, and a considerable amount of miscellaneous information is also given which will be of use to the student and the engineer. This first chapter occupies more than half of the volume, and is practically a treatise on boilers. The second chapter is taken up with distillation, and contains a description of the most recent apparatus for the distillation of water and of mixed liquids of different kinds, with an account of the theory of the operations involved. The third chapter is on evaporation, and treats of liquids of various kinds and the special applications to sugar refineries and to other manufactures requiring the concentration of liquids containing solid matter. We observe, however, that the most recent and one of the most important developments—the Yaryan evaporator—has not been mentioned. This omission may be explained by the fact that it is an American invention, and the apparatus is manufactured solely by American and British engineers. The two last chapters, which are short, are taken up with the subjects of drying and disinfection, and give descriptions of methods and apparatus which apply to a great many different cases. The concluding part of the work will deal with refrigeration, the heating of solids, of liquids, and of gases, and the heating and ventilation of buildings, and the whole will form a very complete treatise on heat and its applications.

Geometrical Drawing for Art Students. By I. H. Morris. London: Longmans, Green, & Co. 1890.

This little work is issued to meet the geometrical need of such students as are following an art course only, but it appears to us worthy of a more extended use. It is a rationally arranged collection of nearly six hundred examples, with appended figures and exercises. Two-thirds of these deal with plane geometry, and include some excellent examples of practical application to architectural and constructive work. Other examples show the use of scales, and there are some problems with restricted and peculiar conditions, all of which are of special value, not only in teaching the use of the subject, but in forcing upon students the more valuable educational factor of personal thought. The chapters on solid geometry deal almost entirely with the projections and sections of the simple solids under varying conditions, not introducing "planes," the examples being well chosen and affording useful exercise in drawing. We think possible confusion would be avoided had the author referred to the fact of their being *four* dihedral angles in the "planes of projection." We find, however, the weakest part of the book in the definitions, which, generally speaking, are not up to the latest geometrical standard. We especially dissent to the division of "quadrilaterals," in which the terms "rhomboid" and "trapezoid" are given to figures which have for some time been called "parallelograms" and "trapeziums" by the best authorities. In many problems references are given to Euclid's proofs, but we see room for a useful increase in these, since we believe it to be an excellent thing to show the practical use of Euclid whenever possible, especially as that is so pertinaciously discredited by students generally. We also notice the absence of sizes in the problems, which is very likely to cause delay in commencing.

Speaking generally, we consider the book will be a useful possession to the self-teaching student, and likewise to the teacher of classes, provided he can prevent his students being tempted by the completeness of the diagrams to copy them without a comprehension of their meaning.

THE MALLECO VIADUCT, CHILI.

The above illustrations, Figs. 1 and 2, for which we are indebted to our contemporary *La Nature*, represent a viaduct which was opened for traffic in October last, and which conveys the Chilian State Railway across a deep valley, at the bottom of which runs the River Malleco, near Collipulli, in the southern part of Chili. The viaduct, which is constructed entirely of steel; has a height of 333ft. from the level of the river, and is composed of five spans, each 232ft. in length. The total length of the viaduct is 1,419ft., the length of the steel portion being 1,160ft. The depth of the girders forming the superstructure of the viaduct is 23½ft., while the rails are laid at a height of about 327ft. from the level of the river. The total weight of the viaduct is 1,550 tons. The designs were prepared by a Chilian engineer, Mr. V. Aurelio Lastaria, and the whole of the steel work, which was erected under the supervision of Mr. E. Vigneaux, was supplied by Messrs. Schneider & Co., Le Creusot, France.

The great difficulty of this undertaking was due to the extreme steepness of the banks of the ravine, and a great deal of time was taken in getting the material into position.

THE ELECTRIC TRANSMISSION OF POWER.*

The lecturer commenced by explaining that before energy could be applied it must be transmitted, and that its transmission could be divided under two heads, the first being transmission over short distances measurable in feet or yards, and the second transmission over long distances measurable in thousands of feet or miles. The electric transmission of energy is generally used over long distances; the chief case in which it is employed over short distances is in the running of machine tools by means of electromotors which are supplied by dynamos fixed in the workshops.

The transmission of energy over long distances only was considered in the present lecture, and it was shown that it could be further divided into the two subdivisions of transmission of "live" energy by means of electrical conductors, wire rope, &c., and of transmission of "stored" energy by means of coal, corn, or falling water. The energy of falling water may be used to charge secondary batteries or to compress air, and the batteries or reservoirs of compressed air may be carried away, and the stored energy of the falling water may be transmitted to the place where it is required. It may easily be seen how corn may be carried from the field to a distance, and there used to feed horses, which will in return do useful work; or how coal may be taken from the pit's mouth to a distant city and there used to produce steam power. The value of any system for the transmission of stored energy depends upon the capital outlay and upon the working expenses, the latter in turn depending upon the storage efficiency, which is the ratio of the useful energy obtained at the end of the transmission to the total energy absorbed by the system. The transmission of stored energy by the transport of secondary batteries was then compared with a similar transmission by means of compressed air, and the following results given:—

Total efficiency with batteries, 58 per cent.; weight of batteries, 100lb. per horse-power hour.

Total efficiency with compressed air, 26 per cent.; weight of steel reservoirs and compressed air, 300lb. per horse-power hour.

The transmission efficiencies of stored energy transmitted by means of coal, corn, or secondary batteries are given in Table III. Taking the case of the batteries and electromotor working on a tram line, it will be seen that if a car, itself propelled by the storage batteries it carries, is occupied in carrying charged batteries from the source of energy, say, a waterfall with generating machinery to a distance, and taking them back when discharged, and the loss of energy in taking the batteries there and back is to be 10 per cent. of the energy originally stored in the battery, then the distance must be 10 miles there and 10 miles back, or 20 miles altogether. The distances given in the table are the theoretical distances, and are too great, as practically there would be considerable losses in inclines on the journey, and in starting and stopping: for these reasons the figures should be looked upon as merely approximations. From the table, it will be seen that the distance over which energy stored in coal can be transmitted with a given efficiency of transmission is enormously greater than the distance in the case of batteries. In the last column the coal transmission is no less than fifty times more efficient than the battery transmission. Besides the greater loss, the capital outlay for batteries is very large, and the depreciation 15 per cent. per annum. The figures in Table IV. are based upon steam power at £10 per horse-power per annum, the steam power being used to generate the electricity for the batteries or direct mains. This table shows that for a transmission of 5 h.p., battery transmission costs more than "live" transmission by overhead conductors, but that it costs less than live transmission by underground conductors (except

where the distance is about one mile or less). The cost of coal transmission for the distances mentioned in Table IV. would vary from £20 to £40 per annum per horse-power delivered. Where large steam engines are used at the end of large coal transmissions the cost per annum per horse-power delivered will be about £10. Tables I., VI., and II. relate to the working of ordinary electrical passenger tramways where secondary batteries are used on each car and charged at particular charging stations.

The lecturer then went on to discuss the transmission of live energy from an electric light central station. In such a station the load due to the lighting varies greatly; during a few hours in the evening the station will probably be worked up to its full capacity, and then the production of electrical energy will be very economical, as all the capital outlay will be actively employed, and also the efficiency of the plant is greater when doing full work than when running light. During the early morning the load on a station may not be more than 10 per cent. of its full capacity, and during the daytime the output is very small; now, if, during these hours of minimum demand, the plant could be run at its full capacity, and the surplus energy distributed to electromotors, the working expenses would be only slightly increased, while the income of the station would be largely augmented.

In cases where motive power is required continuously, as, for example, in a small manufactory working ten hours per day, or 3,000 hours per annum, it would not pay the manufacturer to use electrical power obtained from electric-light mains, as compared with steam or gas power, unless it was supplied at 3d. or less per Board of Trade unit of 1,000 watt hours. Table V. shows the connection between the cost per unit and the cost of a brake horse-power for 3,000 hours. To obtain his power from a small steam engine, the manufacturer would have to pay from £20 to £40 per brake horse-power for 3,000 hours, and the cost of the corresponding electrical energy supplied from electric-light mains at 3d. per unit would be £33·5, as will be seen from the table. Now, the cost of a Board of Trade unit varies from about 4½d. to 12d., the average in London being from 7d. to 7¼d. But in many cases power is only required intermittently, and then electrical power is much more economical and convenient than steam or gas power. Take, for example, the case of a carpenter requiring to run a lathe for, say, two hours. If supplied with electrical power, he merely turns a switch, and the lathe is in motion, while, if a steam or gas engine is used, much valuable time is spent in starting, stopping, oiling, &c. Electrical energy, supplied by central electric light stations, may also be advantageously employed for driving small domestic machines, such as sewing machines, mangles, knife cleaners, &c. At the conclusion of the lecture, Mr. Kapp showed several such small machines, supplied by the Keys' Electric Company, in motion. The first of these was a pump worked by an electromotor, and it was pointed out that in case of fire such a pump would be of great service to increase the pressure in the water mains. The other machines shown comprised a smith's blower, a ventilating fan for hot climates, a washing machine, a churning machine, a knife cleaner, and a boot cleaner. All of these were put in motion, and worked very satisfactorily. The next lecture will deal with the more technical part of the subject.

THE INSTITUTE OF CHEMISTRY.

II.

IN commencing this, our second and concluding article, it may be well to remark that recognition of the fact that no one takes the Institute of Chemistry, as at present administered, too seriously, and cognisance of the honesty of purpose characterising as a whole those acting as its executive, prevented us impeaching it formally in our article of last week.

Would-be reformers of the destructive type, generally with a personal grievance or cherished fad, have arisen from time to time and produced an impression precisely equivalent to their deserts—which, as a rule, may be estimated at zero. We in no way stand in any such position, acting purely as the mouthpiece of the bulk of those members alive to all that threatens the dignity and advancement of their profession, but as yet leaderless and inarticulate. There is not even, as might well be feared, a sharp line of demarcation between officials and private members in their attitude or desires. The best of both are anxious for the welfare of an institution which might be doing much useful work, and between them no petty jealousy exists.

These facts being admitted, we will now formulate some proposals for the enhancement of the usefulness of the Institute and the promotion of the welfare of its members which have long been latent in the minds of those who have considered the matter aright. Whenever any vital question arises in the history of a comparatively youthful institution, it is the merest commonsense to seek guidance from the conduct of older and successful bodies of analogous aims and constitution. Acting on this principle, and taking the most powerful and compact profession in existence—namely, that of law—we see a definite, laborious, and expensive method of entry prescribed, and absolute exclusion of all who have not complied with certain requirements. The result is that those duly qualified are efficiently protected from outside competition and the general standard of competency is raised to a high level. Such protection is a flagrant violation of those economic principles on which healthy trade depends, but is justifiable on the ground of expediency, inasmuch as members of the community at large, being unable to discriminate between good and bad law, submit to the incubus of a close profession for the sake of the guarantee that its members will be reliable

Digitized by Google

in point of knowledge. This, then, would be the boldest and best way out of the present slough, the obtainment of compulsory powers excluding from the practice of chemistry everyone who is not or does not become a member of the Institute. It may be urged that success is unlikely. But is it not worth trying for? It is illegal for an unregistered person to style himself a surgeon-dentist, and the change from an open to a close profession is, in this case, of comparatively recent date. What can be done by a body of men eminently skilful in their craft, but not seriously to be compared in mental calibre as a body with trained and competent chemists, can be done by the Institute. Once convince the public that its interests would be advanced by the compulsory compliance of would-be chemists with a high standard, and the goal is within measurable distance. In this connection public analysis—if its functions and value were properly insisted upon, not only in the technical, but in the lay press—would serve as a powerful platform cry. Show the average human being that his earthly welfare, if not existence, is imperilled by the adulteration of his food and drink, and that adequate check on such adulteration can only be kept by the appointment of men of high ability and probity, and he will promptly clamour to be protected. The path is plain, the means not difficult, the goal attractive, and its attainment is worth a vigorous effort.

It would be folly to neglect to indicate a good course because the best is rejected. Supposing for a moment that the policy just enunciated fail to commend itself to the less enterprising, who may conceivably oppose an inertia too great to be overcome, another may be conscientiously advocated. Taking as a type the largest and most powerful of the purely voluntary societies—the Institution of Civil Engineers—we find that the advantages accruing to the profession which it represents have led kindred professions to form similar associations conducted on parallel lines. Such a testimony to its merit is sufficiently striking, and is warranted by the facts. Although it is open to any unqualified person to put "C.E." after his name, and to compete with men of acknowledged competency, yet the absence of the magic title "Member of the Institution of Civil Engineers" is a tangible drawback. The weight attached to membership in this body is indicated by the fact that its lower qualification, that of Associate Member, is by no means to be despised. What Associate of the Institute of Chemistry, possessed of a grain of professional acumen, fails to suppress the damning title until such time as he has attained the Fellowship? It would be otherwise if the profession and its qualification were raised to the rank that is its right. On examining the regulations of the Institution of Civil Engineers, one is struck by the insistence on a *practice qualification*. No mere intellectual sponge, who can absorb a certain minimum of information and yield it again (somewhat sullied) under the pressure of the examiner, can hope to find admission to its ranks. It is to the credit of the Institute of Chemistry that a step in the same direction has been made in the shape of a requirement, as laid down in the regulations for the admission of the Associateship of students of the Institute, that each candidate shall have been engaged for "four years in the practice of chemistry in the laboratory of a Fellow of the Institute." This is, however, an alternative course, and three years' study in the subjects of theoretical and practical chemistry, physics, and elementary mathematics in any one or more of the Universities or chartered or incorporated colleges or schools approved by the Council is, with child-like naïveté, declared its equivalent! A careful unprejudiced study of the policy adopted by the older and more successful institution would be most opportune and salutary.

We have here completed the consideration of what the aims of the Institute of Chemistry should be. To recapitulate in very brief terms, they are:—(1) The acquisition of compulsory powers converting the practice of chemistry into a close profession, or, if timidity prevail, as a temporary measure; (2) the adoption of a qualification either purely of practice, or of one in which practice largely preponderates, and the consolidation and control of the profession, until the title "F.I.C." becomes the solidest possible guarantee of efficiency.

These aims are impossible of attainment under the present *régime*. Attention must be turned from them, essential as they are, to the humbler but still more immediately necessary task of internal reform. Reverting for a moment to our former article, we would call to mind the fact that we there showed that the sole reason for the existence of the Institute is the advancement of "the profession of analytical and consulting chemistry." The Institute having this object should be administered exclusively by members of that profession; members of other professions, such as that of scholastic and collegiate chemistry, should be welcomed as guests, and, if of sufficient eminence, admitted as honorary members, but should have no voice in the management of its affairs. To transfer the burden of government to the shoulders of such guests or honorary members is a confession of the veriest imbecility; it is neither courteous nor politic, and no professional chemist can contemplate its perpetration without a certain feeling of personal degradation. When the Institute was originally formed, its birth and subsequent existence were sufficiently humble and obscure, and, like a suckling child, its constant cry was for food; all was fish that came to its net, and every deputy assistant demonstrator's *locum tenens* was eagerly absorbed. Times have changed and the Institute of Chemistry is not anxious for such recruits; those already installed cannot well be expelled, but their influence should be neutralised, their action rendered nugatory, and their number not increased. In the present period of tribulation there is a considerable number of professional chemists, many of them men of the highest eminence and commanding ability, who, however, have not a shade of a notion of the accuracy, originality, technical knowledge, and executive faculty absolutely essential for a successful consulting chemist, and who would be as incompetent to do his work or even understand it, as he theirs. Round these is a crowd of budding professors eager to stand well with their masters, imbibing their prejudices, and acting in their interests. It is nothing short of monstrous that the conduct of an association charged with the duty of protecting the profession of analytical and consulting chemistry should be influenced by such as these.

There is one plain rational course to adopt, and that involves an entire change in the constitution of the Council. The election of that body is effected from among those nominated about six weeks before the election takes place. This somewhat lengthy period leads members to overlook the imminence of the elapse of the time available for nomination. It is only a week or two before that they begin to bestir themselves. Such lethargy is inexcusable. Nominations should be made in good time, those nominated being, of course, analytical and consulting chemists of good repute, who are able to find time for regular attendance at Council meetings. A necessary corollary is, of course, that they must be chiefly drawn from those practising in London. With a Council composed of such members, and legislating as it certainly would legislate, speedy alterations for the better would ensue.

Let us consider what action a reformed Council might be expected to take. It would, to begin with, turn its attention to its executive officers, knowing how dependent upon their ability and zeal the welfare of an institution inevitably is. Societies which many could name owe their pre-eminence almost wholly to the character of their secretary. It would be the care of the new Council to see that its secretary was at once a man of ability, standing, and energy; not merely one who would do his duties conscientiously, but zealously and with discretion. It is a misfortune when posts of the kind are filled by men of unblemished integrity and animated by the best intentions, who, through feebleness, vacillation, or native narrowness, allow the affairs under their charge to drift aimlessly or remain stagnant, as their idiosyncrasy directs. A good secretary once secured, other reforms would follow; the Council would instruct that officer to put himself in touch with the leading technical journals and secure their co-operation for the publication of the proceedings of the Institute in their pages. He would further be required to keep the Institute continually *en évidence*. A young institution striving to gain public recognition must not fail to let its doings be known as widely as possible. In particular must it put itself into official communication with all public bodies controlling appointments open to its members; it must endeavour to obtain from such bodies pledges that the appointments in their gift shall be restricted to such as hold the qualification it confers. Something in this direction the Institute has already done; much more remains to be done. Local authorities would, as a rule, be only too glad to have some trustworthy criterion to guide them in their choice, and if the value and importance of Fellowship in the Institute (which is even now considerable, and would be far greater with a rigorous practice qualification) were made known to them, they would assent freely to the necessity of its possession by their appointees.

Consonant with those aims would be the active supervision of its members by the Institute. Officers at present exist termed "Censors," and the idea involved in their official existence is excellent. The posts, however, are at present absolute sinecures. At first sight this appears to be a testimony to the immaculate character of the Fellows that is as rare as it is gratifying. Possibly the absence of any direct incentive to exercise the functions of the office may be a factor in its virtual abrogation. It is needless to say that censorship would be very real under an improved condition of things. Steps would be taken, warily and with frequent reference for instruction to the practices obtaining in older professions, to build up a code of chemical ethics, to formulate rules of professional etiquette, as well as to keep a watchful eye on malpractices, overt or covert.

In one thing, and perhaps only one, would the Council, as it should be, imitate its predecessor. It would *not*—at least in its early days—publish a Journal. For the present the Institute has no strength to spare for such work, excellent though it might be; all its forces are needed for winning its way, and every hour and every penny spent for other objects are so much waste effort. Nevertheless, as has been already indicated, it would avail itself of the co-operation of the press to publish its "Proceedings" to a larger audience than they at present reach, and by relying upon its friendly aid would at length gain the public ear. So alive are we to the interests of the profession for whose benefit we have given so much of our space, that we would endeavour to be the foremost in granting such facilities.

Let the Fellows of the Institute of Chemistry abandon their present inactivity in their own affairs, and their vicarious interest in those of the Chemical Society (if they cannot find energy for both), and make a strenuous effort to raise the Institute, and through it their profession, into a position of honour where it need yield precedence to none.

SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

At a meeting held on the 6th inst., Mr. Ivan Levinstein being in the chair, a paper was read by Dr. Carl Otto Weber, on "Magnesia Cement." After referring to the importance of the cement industry, which had now been carried on for more than seventy years, Dr. Weber said that although there were a great variety of cements not of much scientific or technical importance, there were a few which were worthy of more attention being paid to them. Among these were the magnesia cements, though he did not expect that they would seriously rival ordinary silicate cement. The hydraulic properties of magnesia had been observed long ago. Deville discovered that magnesium chloride and calcium carbonate formed a hard cement. The hardness of magnesia cements depended on the degree of compactness of the magnesia used. That prepared from $MgCl_2$ was of great density, though its cost prevented its general use. Dolomite had been tried, but afterwards this manufacture was abandoned. When at a low red heat the CO_2 of the $CaCO_3$ was given off, and a cement was formed. Sorel had discovered that magnesium oxychloride formed a quick-setting mass, having a high tensile strength equal to one ton on the square inch, or three times the strength of ordinary Portland cement. The magnesia must be of great density, and very free from CO_2. It was made by mixing MgO with an 80 per cent. solution of $MgCl_2$. A diagram was exhibited, showing the results obtained from different proportions of oxide and chloride of magnesia. It was seen that the tensile strength, which was greatest with equal proportions of the two compounds, decreased directly as the $MgCl_2$ increased. Experiments to determine the effect of water in the cement had shown that the tensile strength was inversely proportional to the amount of water present. The setting of Sorel's cement was due to the same cause as the setting of Portland cement—*i.e.*, assimilation of water, and the amount of water present formed an important factor. This cement, being acted on by water, was useless for outdoor work. Stones and emery wheels made from it had turned out failures. The author had tried to replace the $MgCl_2$ by some other body, and, after finding that the chlorides of the alkalies and alkaline earths were all objectionable, he had found that the best results were to be obtained with anhydrous silicic acid; 15 per cent. of silicic acid gave the hardest cement, though it was not suited for hydraulic work. His mixing was—

100 magnesia.
15 silicic acid.
9 magnesium chloride (80 per cent. strength).

This gave a tensile strength of 1,788lb. per square inch. He had used this cement sucessfully for engine beds, and strong building stones resembling polished marble had been made from a mixture of it with sand and gravel. He could not say that it stood the atmosphere very well, but possibly his further experiments would lead to still better results.

In the discussion Mr. Bell referred to the fact that magnesia was considered injurious in Portland cement, saying that contractors stipulated that cement should not contain more than 1 per cent. He had known concrete in large works to be all swollen up owing to magnesia. Dr. Gerland and Mr. Thomson inquired as to the formula of magnesium oxychloride.

Dr. Weber, in his reply, said that the magnesia in Portland cement acted differently than it did in magnesia cement. In the quick-setting Portland cement the setting took place before the magnesia was hydrated, and the bad effect of magnesia must no doubt be put down to unequal setting. With respect to magnesium oxychloride,

Digitized by Google

he did not think there really was such a compound, but that it was a hydroxychloride. In reply to a query as to whether the cement was suitable for acid tanks, he could not say that it was, as, although it was unacted on by strong acids, dilute acids had considerable action on it.

LONDON SECTION.

At a meeting of this Section, held on the 16th inst., Mr. W. Mackean read a paper on "Incandescent Gas Lighting." He stated that, while all were agreed that the ordinary methods of illumination by gas left much to be desired, and that the electric light alone could claim to approximate to perfection, yet the expense of the latter would militate against its adoption for some time to come. If, therefore, a method of lighting could be devised utilising the existing supply of gas and giving a light comparable with that of an incandescent lamp, it would fill a place and be a practical success. Such a light was that produced by the incandescence of refractory materials heated by an ordinary bunsen flame. In the subsequent part of the paper the Welsbach light was chiefly referred to, though some information was given respecting the Clamond and other systems. The hoods or mantles of refractory oxides used in the Welsbach lamp are made of textile material saturated with a solution of a salt of the requisite rare earth, such as zirconia, and the organic matter burnt off before use by simply igniting the cotton threads near the top of the mantle and allowing it to burn downwards. The colour of the light, its amount for a given consumption of gas, and the lasting powers of the mantles greatly depend on the precise mixture of rare earths used. To hear names which one has associated with bodies exclusively interesting to the pure chemist uttered trippingly, as the mere raw material of an industry of no little importance, was as striking as it was instructive. Zirconium, lanthanum, didymium, thorium, yttrium, and cerium were spoken of with the freedom one uses towards their common brother, aluminium. In making the mantles the presence of alumina and magnesia is detrimental. The same is true of iron, complete freedom from that body being essential. As to the candle-power of such lights, it may be said that it varies considerably both with their nature and age; a good average result appears to be 4–5 c.p. per cubic foot of gas. The perfect combustion of the gas, when burnt in an incandescent light—in itself a distinct advantage—was adverted to. If used in a reducing flame the mantles deteriorate. At present complete success has not attended efforts to utilise water gas as the incandescing agent, but further experiments are being made in this direction, and Mr. Scudder, of the British Water Gas Syndicate, hopes eventually to arrive at better results.

In the discussion which followed, Mr. Dyer wished for further information about the rare earths used, and spoke of the deterioration of such incandescent burners as had come under his notice.

Mr. Allen inquired whether these earths became insoluble in acids on heating, as alumina does at high temperatures, thus militating against ease of re-working.

Mr. D. A. Sutherland spoke of the utility of the incandescent gas light in the laboratory for all operations needing nice discrimination of colour, a quality the existence of which Mr. Mackean in his reply confirmed.

Messrs. Cross and Bevan then presented a note on the "Volumetric Estimation of Alumina," of a controversial nature, relative to the dispute that has arisen between themselves and Professor Lunge as to the precise point at which neutrality is reached in titrating with methyl orange. They brought their views to the test by making titrations in presence of the assembly, first to the point they considered final, and then to that corresponding to Lunge's statements. There was ocular evidence thus afforded that the change took place when it should, according to their contention. The incandescent gas lights, which had been used for illustrating Mr. Mackean's paper, showed the change of tint admirably.

Mr. Bertram Blount remarked that the evidence on the authors' side appeared conclusive, and reminded the meeting that differences between different observers in titrating with methyl orange were sometimes due to slightly abnormal eyesight. Persons in the least degree colour blind, as many unconsciously were, failed to perceive the change from pink to yellow, and *vice versâ*.

Mr. Allen said that bad methyl orange was frequently sold, a statement confirmed by other speakers.

Mr. Bevan, replying, could advance no hypothesis to account for the discrepancy between their results and those of Professor Lunge. Samples of the indicator had been exchanged, and titrations made by independent observers, to no purpose; he hoped those sufficiently interested would try the experiment for themselves.

Dr. Johnstone, having read a note on the determination of glycerine by the permanganate method, the proceedings terminated.

Notes.

AGRICULTURAL EDUCATION IN SICILY.

In agricultural schools and colleges Sicily is much behind the age. The province of Catania is the most advanced—there is a school of viticulture at Catania, and one of agriculture at Caltagirone. In some districts agricultural education is taught in the communal school. In the neighbourhood of Palermo, near the Favorita, there is an agricultural college of imposing appearance founded by the Prince of Castelnuovo, but it does not as yet appear that any of these establishments have had any effect in raising the general character of Sicilian agriculture.

MINING IN ECUADOR.

A Foreign Office report from Ecuador states that the Zaruma Gold Mining Company continues the extraction of gold from the Portobello mine, getting out about 400oz. to 500oz. of gold per month, and a proposal has been made to augment the stamping power in order to increase the produce. Elsewhere, however, things are not so satisfactory. The works on the Quebrada mines have been entirely suspended. The mine has been flooded, and the whole of the capital of the company is said to be exhausted. The Telephono mines have not been actively worked either, and some explorations by English and French syndicates on other mining properties have so far given no definite returns.

BAUXITE AND KAOLIN IN ARKANSAS.

Dr. Brauner has recently reported to the Government of the United States that extensive deposits of bauxite exist in Arkansas in irregular patches. As this mineral has only hitherto been found in small quantities, and, with the exception of a single bed in Georgia, never before in the United States, the find is likely to prove a valuable one. The growing demand for the better class of refractory crucibles and tiles has lately caused an increased use of this mineral, and as it is also employed in some of the aluminium processes, and for the manufacture of alum and aluminate of soda, the discovery is of great commercial interest. The kaolin deposits occur in the same districts, but their extent has not at present been determined with any minuteness.

TRADE IN ECUADOR.

During several years the amount of exports from Guayaquil, in Ecuador, to Great Britain have shown a steady decrease, owing mainly to the fact that cocoa, which formerly came to this country for distribution to the Continent, now goes direct to Amsterdam, Rotterdam, Antwerp, and Hamburg. Trade between Ecuador and the United States is increasing. The waterworks for Guayaquil have not yet been completed, although the flexible tubing has been successfully laid across the bed of the Guayaquil river; the work on the reservoirs at Santa Anna hill have been actively continued; tubes have been laid throughout the city, and some progress has been made on the laying of the tubes from the source of the supply to Duran. The railroad has been but very little advanced, but trains are now running regularly from Duran, in front of Guayaquil, to Chimbo, at the foot of the Cordillera, and a special steamer belonging to the company makes the regular service from Guayaquil to Duran.

IRRIGATION WORKS IN PERU.

In a despatch from Lima to the Foreign Office, Sir C. R. Mansfield states that agricultural interests in Peru have to struggle against two deficiencies—the want of water in the first place, and the want of labour in the second. Where capital is at hand to promote irrigation vast tracts, now little better than deserts, might be rendered of great fertility. He says that a notable experiment in such a direction is in contemplation in the neighbourhood of Piura, in the department of the same name, where a company proposes to utilise the waters of the River Piura for the irrigation of some 400,000 hectares of land, at present a sandy waste and absolutely worthless. The department of Piura is the principal cotton field in Peru; the project is an important one, and the result will doubtless be highly remunerative, while, if such prognostigations be realised, other enterprises of a similar character will be set on foot in various parts of the Republic, in the department of Ica, for example, also a cotton district, and elsewhere.

THE RECENT DISCOVERY OF NATURAL GAS IN ENGLAND.

In his lectures on "Gaseous Fuel" (since published by Messrs. Whittaker & Co.) Mr. Thwaite gave it as his opinion that beneath the salt beds of Cleveland, Cheshire, and Ireland both natural gas and oil would be found. At Mr. Verdin's request, Mr. Thwaite elaborated his theory, which was in due course submitted to the Salt Union, with the result that the Salt Union decided to put the theory to the test of the drill, and borings have been proceeding simultaneously in Cleveland and Cheshire. It is reported that in the former district natural gas has been struck, and issues in great volumes. This discovery is of great national importance, as it may mean the conferring by nature on Cleveland all the natural advantages possessed by the great iron centre of Pittsburgh and district, and prove of enormous advantage to the metallurgic and chemical industries carried on in the North Yorkshire ironfield. We hope that the test in Cheshire may be equally satisfactory, and thus confirm to the full Mr. Thwaite's predictions.

CANDLE POWER OF INCANDESCENT LAMPS.

Much has been said recently as to what incandescent lamp should be considered the normal one. A general opinion is that 8 candle-power is best. Of course, electric light engineers naturally want to have the standard as low as possible, for if the public believes an 8 candle-power lamp gives as much light as a gas burner consuming 5 cubic feet an hour, of course it makes the electric light come out well as regards cost. With a good gas burner much more than eight candles can be got from 5 cubic feet of gas an hour. It must also be remembered that the usual way of measuring an incandescent lamp on the photometer is very much in its favour. An 8 candle-power electric lamp gives eight candles in a horizontal direction only, and sometimes only in one horizontal direction if the filament is flat. In a vertical direction the light may be only two or three candles. The mean light in all directions may be much less than eight candles. An 8-candle gas lamp, as the flame is transparent, gives the full light in all directions, except where the shadow of the burner obscures it. An 8-candle gas lamp is thus superior to an 8-candle incandescent light. Another advantage of gas is that the flame is generally used naked, while the electric light, even if not in an outer globe, gets slightly blackened or dusty, and loses a large proportion of its light. It is surprising what a large percentage of light is wasted by an almost imperceptible blackening or external soiling of the lamp bulb.

THE ENGINEERING SCHOOL, CORNELL UNIVERSITY.

Since publishing the article on this subject in our issue of the 30th ult. we learn that the number of students registered this year is something like 450, including a considerable number of graduates from other colleges, taking, in most cases, advanced work in research and higher engineering; and of the whole list, nearly one-half are selecting the electrical work in specialisation, the others dividing between general engineering, steam and naval engineering, and other special lines of work. The upper classmen, to the number of about 200, are all taking work in the mechanical laboratory, which is being considerably extended to meet this large demand. At the end of the year it will have its 200 men assigned to work in strength of materials, and other work of research in that general direction, to engine and boiler testing, and to a great variety of special investigations. The laboratory plant will include a triple-expansion 150 horse-power engine, which has been ordered from Messrs. E. P. Allis & Co., Milwaukee, to be used for experimental purposes in the mechanical laboratories. The engine is to be so arranged that it may be run single, double, or triple expansion, with or without steam jackets, &c., and will be fitted with all appliances necessary for experimental work. There will also be a number of smaller and specially constructed engines and boilers, including the 500 horse-power heating plant of the University; collections of steam pumps and injectors; a plant illustrating Hirn's analysis; several air and gas engines, including all the usual types; turbines and rotary pumps; several testing machines of 15,000lb. to 20,000lb. capacity, others of 40,000lb. and 50,000lb., one of 100,000lb., one of 200,000lb., and one of 300,000lb., which has been ordered from Messrs. Olsen & Co., of Philadelphia. This machine will weigh several tons, and extend up through three stories of the building.

Patent Record.

APPLICATIONS FOR PATENTS.

The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

2nd February, 1891.

1845. Veale & Coon..... Regulating steam, water, and other engines.
1846. King, J..... Machine for drying, concentrating, or carbonising fertilisers, ochres, oxides, and other materials, and for concentrating and evaporating liquids.
1851. Shires, J..... Woollen condensers.
1858. Craig & Stevenson ..... Pipe-making machines.
1854. Heywood & Holland ... "Pegging" machines for finishing pile fabrics.
1877. Critchley, T..... Reeling, warping, winding, and gassing machines.
1880. Sykes, Jun., & Smith ... Railway signalling apparatus.
1893. Reverdy, E..... Decorticating or hulling machine.
1903. Abel, C. D..... Gas and oil engines (*The Gas Motoren Fabrik Deutz*).

3rd February, 1891.

1910. Sayer, R. C. ..... Gas engines.
1927. Begg, W. ..... Looms.
1935. Gaunt, J. W. ..... Automatic stop motions for slubbing and other drawing boxes.
1946. Allison, H. J. ..... Platform elevators (*Ruddell*).
1947. Woodsum & Woodsum... Engine attachments.
1961. Menelly, C. D..... Roller bearings.
1966. Yole & Muirhead ..... Stamping machines.
1973. Cole, W. ..... Harvesting machines.
1974. Bickle, T. E. ..... Valve for rock drills.
1976. Masterman & Woodhouse & Rawson United, Ld. ..... Oil filter.
1979. Roberts, J. ..... Carpet-cleaning machine.
1990. Imray, O..... Ore concentrators (*Bertenshaw*).

4th February, 1891.

2003. Fox, G..... Railway couplings.
2004. Sutcliffe, W. ..... Looms.
2006. McCallum, D. ..... Float-feed lubricators.
2014. West-Field, E. S. ..... Gas engines.
2020. Wynne, W. R. ..... Shaft bearings.
2037. Fraser, G. ..... Ore crushing mills.
2053. Gray, A. ..... Vaporisers for hydrocarbon engines.
2057. Reilander & Topham... Self-acting forging machine.
2068. Lockwood & Adamson Apparatus for dyeing, washing, or scouring tops, or slubbing warps.
2071. Blanks & Lefebure..... Brick-making machine.
2073. Munns, W. H..... Traction engines (*Pond*).
2076. Munns, W. H..... Turbine water-wheel (*Elmer*).
2077. Munns, W. H..... Well-drilling machines (*Miller & Canman*).
2080. Munns, W. H..... Stone-crushing machines (*Clair & Varich*).
2084. Richardson, J. ..... Multitubular boilers.

5th February, 1891.

2090. Whitehead, J. ..... Caps used in spinning and twisting machinery.
2091. Hacking, W. A..... Shuttle-box motions for looms.
2146. Lake, H. H..... Boiler and other furnaces (*Hawley & Sapp*).
2149. Ladds, P..... Boilers.
2150. King, F. J. ..... Apparatus for making metal boxes.

6th February, 1891.

2166. Wigzell & Pollit ..... Boiler feed pump for steam engines.
2167. Laidler & Thompson ... Adjustable pitch reversing propeller.
2178. Hartung, H. ..... Water gauge valves.
2185. Adams, W. R. M. ..... Magazine guns.
2208. Isherwood, A. ..... Wood picking sticks for looms.
2210. Hartley, J. W..... Gas engines.
2213. Storch, E. ..... Slide valves.
2221. Edward & Edward ..... Machinery for covering telegraph and telephone cables and wires with lead.
2230. Allin, S. S..... Apparatus for dry concentration of ores.

7th February, 1891.

2262. Burt, T. P..... Weft forks and picking motions of looms.
2263. Burgess, Ledward, & Crompton ..... Looms.
2264. Chambers, R..... Steam boiler furnaces.
2292. Needley, F. ..... Thrashing machines.
2295. Dèmoulin, G. M. ..... Valves and valve gear for steam engines.

ELECTRICITY.

2nd February, 1891.

1905. Atkinson, L. B..... Electrical distribution.

3rd February, 1891.

1908. Maxwell, D. ..... Switches.
1912. Lewis, J. S..... Galvanometer.
1913. Lewis, J. S..... Bells.
1923. Binswanger, G..... Switches.
1963. Dewey, M. W. ..... Apparatus for soldering cans and the like.
1968. Lake, H. H..... Lamps or lighting apparatus (*Macquaire*).
1969. Lake, H. H..... Signalling apparatus (*Burrell*).
1987. Clark, A. M. ..... Lamps (*Easton*).
1988. Imray, O. ..... Autographic telegraphs and automatic switches for same (*The Writing Telegraph Company*).

4th February, 1891.

2010. Berg, E. ..... Signalising telegraphs.
2033. Lowrie & Hammond..... Dynamos.
2040. Müller, H. ..... Switches for secondary batteries.
2045. Hutchinson, R. R..... Ore stamping and pulverising apparatus.
2061. Thompson, W. P. ..... Lamp holders (*Moore*).
2067. Baur & Dieselhorst ... Transformers.
2068. Siemens Brothers & Co., Ld. ..... Semaphore signal apparatus (*Siemens & Halske*).
2069. Siemens Brothers & Co., Ld. ..... Apparatus for working semaphore signals (*Siemens & Halske*).
2081. Gisborne, C. A. ..... Multiple circuit telegraphy (*Keeley*).

5th February, 1891.

2115. Dean & Jubb ..... Brushes for dynamos.
2152. Woodburn, J. C. ..... Switches.
2155. Nebel, J. ..... Armatures for dynamos.

6th February, 1891.

2199. Cox, Robinson, & Gritton ..... Automatic switches.
2200. Attenborough, E. ..... Motors.
2201. Spagnoletti, J. E. ..... Laying and insulating underground mains.
2219. Lever, E. E. ..... Arc lamps.
2225. Berlier, J. B. ..... Motors for electric railways.

7th Feburary, 1891.

2289. Siemens Brothers & Co., Ld. ..... Block signalling apparatus (*Siemens & Halske*).
2293. Horn, W. W. ..... Cut-out fuse (*Whittingham*).
2297. Hazeltine, C. W. ..... Arc lamps. (9th July, 1890)

CHEMISTRY.

2nd February, 1891.

1883. Willcox, B..... Manufacture of dyestuffs of anthracene and anthraquinone (*Farbenfabriken vormals Friedrich Bayer & Co.*).

4th February, 1891.

2000. Hart, P. ..... Treatment of composite ores containing zinc.

5th February, 1891.

2089. Johnson, J. ..... Manufacture of steel (*Blair, Jun.*).
2134. Greenwood, J. ..... Production of caustic soda.

6th February, 1891.

2224. Lake, H. H..... Manufacture of chromates, bichromates, and other chromium compounds (*Massignon & Watel*).
2234. Parkes, H. ..... Manufacture of ferruginous alloys.

MISCELLANEOUS.

2nd February, 1891.

1855. Moseley, J. ..... Woven bands and belts.
1871. Ambler & Branter ..... Moulding hollow ingots and other tubular articles.
1889. Sebor & Schulz ..... Belt fasteners.

3rd February, 1891.

1922. Purkis, H. S. ..... A communicator and fire alarm.
1986. Sparr & Sparr ..... Screw propellers.

4th February, 1891.

1995. Hield, R. ..... Hinges.

6th February, 1891.

2178. Davies, R. ..... Adjustable spanner.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

4. Cory.
180. Edwards (*Cassalette & Kunhardt*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

GAS ENGINES.—*C. D. Abel, London.* (*Die Gas Motoren Fabrik Deutz, Köln, Deutz, Germany*).—The object of this invention is to provide means of preventing the premature explosion of the explosive charge immediately on its introduction into the cylinder of engines working with a cycle of four or two strokes. For this purpose the inventors introduce into the cylinder, during the exhaust stroke, a quantity of steam or a spray of water. The water is at once converted into steam, and, after cooling the residuary products of combustion, as is also the case with steam when used, escapes through the discharge valve. The steam or water is introduced through a suitable pipe during the discharging period under suitable pressure, the supply being governed by a suitable valve normally held closed by means of a helical spring and operated by a cam on a countershaft of the engine through the medium of a bell-crank lever. When using water, the passage admitting it is provided with a projecting perforated nozzle directed towards the cylinder. Three claims are made.—No. 3774. March 10th, 1890. 6*d*.

STEAM ENGINE CUT-OFFS.—*A. J. Boult, London.* (*G. Fussell, Lockport, New York, U.S.A.*—Referring to the accompanying illustrations, Fig. 1 is an elevation and Figs. 2 and 3 details of an engine fitted with the improved cut-off. The valve box A is divided horizontally, the feed pipe communicating with the upper part, and the exhaust with the lower part. Two ports communicate with both sides of the partition and each end of the cylinder, and valves sliding between gibs on the upper and lower faces of the partition, and are connected with rods B C operating said valves. To the rod C is hinged a second rod operated from any

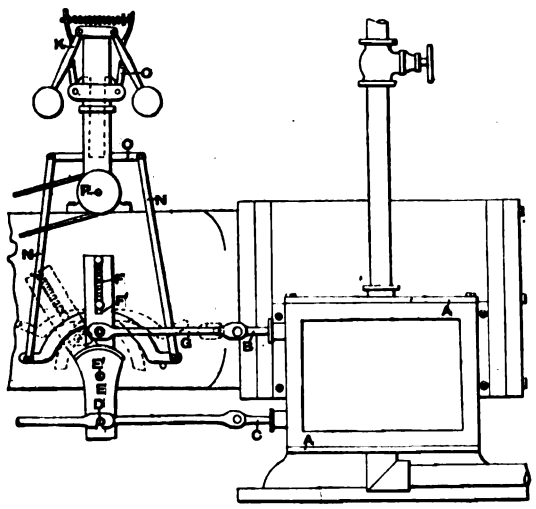

FIG. 1.

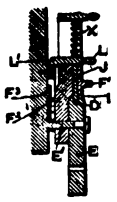

FIG. 2.

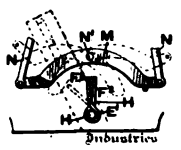

FIG. 3.

part of the engine by suitable rod, and one end of each of said rods embraces a stud D on an arm E pivoted to the engine frame at E^1. A second arm is mounted at E^1, having a pin F^1 to which is connected the link G connected to B. On the back of this arm (Fig. 2) is a pin F^2, and above it is a second pin F^3 fast in the frame of the engine, and bearing on both sides of these pins are the ends of a spring H coiled around a stud H (Fig. 3). The second arm is provided with a shoulder I overhanging the top of E, and is provided with a sliding dog J forced downwards by a spring X into a hole in the top of E, out of which it can be raised by a handle L. At the back of L is a toe L^1 riding over two cut-off segments M (Fig. 3), pivoted to the engine frame at N^1 and connected at their outer ends by rods N to the slides O of a governor constructed substantially as shown (Fig. 1), and driven from P. The action is as follows:—So long as the engine runs at its normal speed, dog J connects E and F, but, as the speed increases, the governor slides rise, so raising J through M and N and releasing E from the second arm. The spring H now comes into play, and tends, through stops F^2 and F^3, to hold E perpendicularly, so cutting off the steam supply. The exhaust valve continues to operate through E, and this operation continues until the engine speed is properly reduced, when the dog J is allowed to fall, so connecting E and F. Eleven claims are made.—No. 18090. November 10th, 1890. 8*d*.

STEAM BOILERS.—*E. Jones, Leeds.*—The invention relates to apparatus for separating water from steam as the latter passes from the boiler. This apparatus consists of a tube, preferably square in cross section, and formed in two parts, longitudinally, each part having a series of inclined transverse blades or deflectors. These blades are so arranged that when the two parts are put together the projecting ends of each of one set of deflectors extend a slight distance between each pair of the other set of deflectors, so forming a sinuous course for the steam. The blades are at such a distance apart that the area of the passage between them is about equal to the area of the exit pipe, to which one end of the apparatus, which is fixed inside and to the upper part of the boiler, as is well understood, is fixed, the other end opening into the boiler. The upper blades are inclined in the direction the steam has to travel, the lower series being parallel therewith. When the separator is fixed horizontally in the bottom of the tube near the point of junction of each blade, an opening is formed for the escape of water. These openings may diminish in area as they near the exit, but the total area of all the openings should not exceed that of the inlet to the separator. Claims: (1) The apparatus for drying steam as described; (2) adapting to the steam pipe of a boiler a box or chamber having two series of transverse deflectors, the one series arranged intermediate of the other, and against which the wet steam strikes, the watery particles being thereby deflected downwards to suitable openings. —No. 4594. March 24th, 1890. 6*d*.

SIGHT-FEED LUBRICATORS.—*W. A. G. Schönheyder, London.*—In the annexed illustrations Figs. 1 and 3 are vertical sections, and Fig. 2 a sectional plan of a lubricator constructed according to this invention, and operated in the usual manner by means of condensation water. Fixed to the oil container A is the screwed

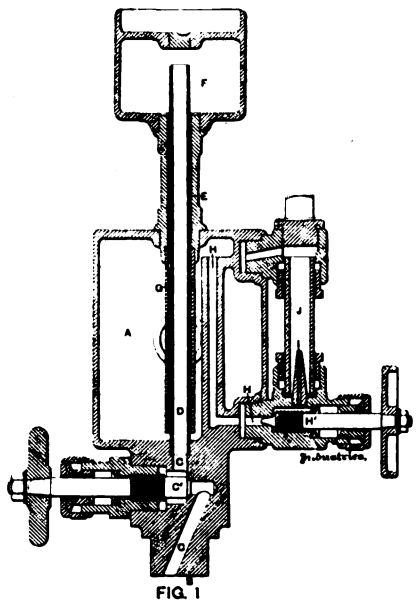

FIG. 1

shank B, by means of which the lubricator is attached to the cylinder to be lubricated. A channel C governed by valve C^1 passes through B and is connected to a pipe D, passing through A and a sleeve E into the condensing chamber F. The pipe D does not fit E so that connection is formed between the chambers F and A, which connection is made at the lower part of A by means of a tube G. A passage H governed by valve H^1, opening into the upper end of A, leads to a nozzle I in the glass tube J, which is filled with water. From the top of J a passage K through the plug K^1 leads to a second passage L (Figs. 2 and 3), leading to the passage C. The operation is as follows:—The valve C^1 being opened steam is allowed to pass to chamber F, where it condenses, and passing down through tube G enters A, so causing the oil to rise and flow into passage H, thence through valve H^1 and nozzle I, through the water in J, and passages K and L into C, and thence to the cylinder, the flow being regulated by valve H^1. Suitable plugged openings are made in the top and bottom of A for emptying out the condensation water and refilling with oil. Claims: (1) In a sight-feed lubricator, the combination with the oil chamber A, nozzle I, glass tube J, passage C, valve C^1, and tube D of passages H and L formed in the body of the

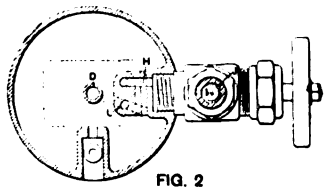

FIG. 2

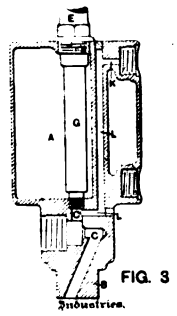

FIG. 3

chamber A, of which H establishes a communication between the chamber A and the nozzle I, while L establishes a communication between the top of the glass tube J and a passage leading to the part to be lubricated; a condensing chamber F carried by an extension E above the oil chamber A, into which the steam tube D passes, and an annular passage surrounding the tube E leading from the bottom of the condensing chamber to near the bottom of the oil chamber, substantially as described. — No. 3525. March 5th, 1890. 8*d*.

RAILWAY CHAIR KEYS.—*E. Parsons, London.*—The invention has for its object an improved lock for fastening railway chair keys. This lock consists of a flat metal bar of steel or other suitable metal, one part of which is bent back over the other part to form a spring. Formed at each end of this second part are hubs between which the chair fits, and formed on the other or spring part are a number of teeth or serrations. The railway chair key is driven between the rail and this lock, which is held rigid by means of the hubs thereon embracing the arm of the chair, and which holds the key rigid by means of its teeth or serrations, the said toothed part entering a longitudinal slot in the key. Claims: The combination with a double resilient bar with two ends adapted to embrace the chair of a toothed face adapted to bite the key as set forth.—No. 3573. March 6th, 1890. 6*d*.

ENGINE GOVERNORS.—*G. H. Firth, Clayton, Manchester.*—The invention relates to a differential speed regulating apparatus for steam and other engines. Referring to the annexed illustrations, Fig. 1 is a front elevation, Fig. 2 an end elevation, and Fig. 3 details of such an apparatus. The apparatus is mounted upon a base-plate A provided with a socket A^1 for fixing the same on a pillar or stand, or upon a similar suitable bracket or plate. The plate A carries bearings B^1 B^1 for the shaft B upon which the worm B^2 is fixed and gears with the worm-wheel C. The shaft B is driven from the crank-shaft of the engine and rotates the worm-wheel C at a reduced speed. The worm-wheel revolves on a collar D^1 of the hollow stud D, the section of which is indicated on Fig. 1. The stud is fixed on the base-plate A by means of the nut D^2. The bevel wheel E is cast with or fixed to the worm-wheel C, and rotates with the same. Facing the wheel E another bevel wheel F of the same size is mounted upon the stud D and rests on a shoulder of the same. The wheel F is formed with a clutch F^1 at its back, into which the projections G^1 of a sliding clutch G enter. A shaft H passes through the hollow stud D, and is supported at the top in the cross-rail I carried by the pillar I^1 and bracket M fixed upon the base-plate A. A clutch H^1 is fixed on the shaft H, into which the teeth G^2 of clutch G enter when the latter is held up in the position shown on the illustrations by the pins N^1 of the forked lever N which enter a groove G^3 of the clutch G. The shaft H receives a uniform rotation from a motor independent from the engine to which the apparatus is applied, and drives through the clutches G^1 and G^2 the bevel wheel F in a contrary direction to the wheel E, and at a constant speed corresponding to the speed of E when the engine is driving the crank-shaft at its normal speed. Between the wheels F and E a third bevel disc or plate-wheel L is placed upon the stud D. The plate of L contains an opening and bearings for the bevel wheel L^1 to run in. This wheel L^1 is in gear with both wheels E and F as shown. When the latter are rotated in opposite directions at the same speed, the wheel L^1 simply rotates, and no movement of the wheel L takes place, but when the speed of the engine and wheel E increases, the wheel L^1 rolls on wheel F, and the wheel L is turned in the same direction as wheel E, while, if the speed decreases, the wheel L^1 rolls on E and the wheel L is turned in the same direction as F. These motions are transmitted through the bevel pinion K running in a boss on bracket M and the clutches K^1 K^2 to the shaft O. The shaft O is utilised to adjust the length of one of the rods connecting the governor with the throttle valve or automatic ex-

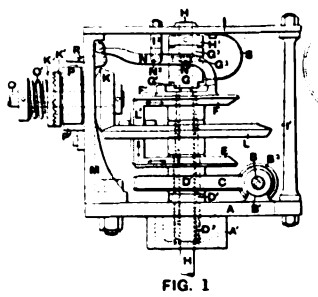

FIG. 1

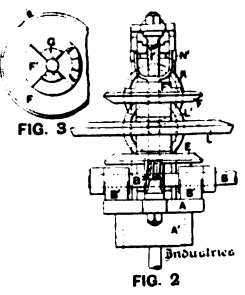

FIG. 2

pansion gear so as to increase or reduce the pressure or admission of steam. To prevent the rotation of O, and so breakage, when the engine is stopped the wheel K is fitted loosely on O and carries a serrated collar K^1, against which a second collar K^2 sliding on but rotating with O by means of a spring O^1 is pressed. Thus, when O is stopped and K continues to revolve, K^1 and K^2 will be forced out of gear. For the purpose of stopping the engine from any part of the building an electromagnet P supported on a bracket P^1 is used. Above P is a bell-crank lever R on a stop on one arm of which rests one end of a lever N pivoted at N^2. A stud N^1 works in a groove in G, and the end of N rests on F, and a spring S tends to force N downwards. Thus if the circuit around P is closed R is drawn downwards, so releasing N, which then engages the cams F^1 and F, so stopping F and drawing G downwards out of gear with H^1. Four claims are made.—No. 2851. February 22nd, 1890. 8*d*.

STEAM BOILER FURNACES.—*H. C. Paterson, London.*—The object of the inventor is to provide means for preventing or consuming smoke, and so economising fuel in steam boiler furnaces. To this end the inventor forms in the front part of the furnace or in the door thereof passages, receiving air from outside the furnace at their lower ends, and conveying it upwards and delivering it into the upper part of the furnace, a transverse section of these passages being of a form somewhat resembling the letter S, the outlets however being curved so as to direct the air towards the part above the fire. A deflecting plate is pivoted on studs at each side of the furnace in the upper part thereof by means of slotted arms fixed thereon, and this plate, by means of nuts on the ends of the supporting studs, can be fixed at or altered to any position until the most beneficial direction of the air is obtained. Claims: In furnaces a passage or passages in the door or front of the furnace receiving air at its lower part and discharging it into the upper part of the furnace beneath a deflecting plate, by which it is directed downwards into the fire, as described.—No. 1101. January 21st, 1890. 6*d*.

RATCHET SPANNERS.—*P. Mitchell, West Hartlepool, Durham.* —The spanner constructed according to this invention consists of a circular box or socket, in one end of which is formed a recess adapted to fit the nut to be turned. One half of this socket is of a larger diameter than the other, and around the smaller part is placed a loose ring, which is prevented from slipping off by means of a washer fixed to the end of the socket, and of a slightly larger diameter than said end. A suitable lug is formed on the periphery of this ring, to which is hinged a lever, having formed on it, beneath the fork by means of which it is hinged to said lug, a tongue or knife edge, which, when the lever is brought to such

Digitized by Google

a position that it stands out at right angles to the axis of the socket, enters one of a number of slots formed in that part of the socket which is of the larger diameter and parallel to the axis of the latter. When, however, the lever handle is raised so that it stands at an angle of, say 30°, to the axis of the socket, the tongue will be disengaged, so that the lever, together with the ring, may be moved without moving the socket. Claims: A wrench or spanner, comprising a box or socket designed to receive the nut to be turned, and a lever pivoted to a ring on one part of the said socket, and provided with a tongue adapted to engage with slots on the other part of the said socket, as described; (2) the manufacture and use of the improved wrench or spanner, as described. —No. 17617. November 3rd, 1890. 6*d*.

ROLLING MACHINES.—*S. Fox, Leeds.*—The invention relates to machines for rolling articles of channelled or trough-like sections from mild steel plates, and which are constructed as follows:—Fixed to a suitable base are two vertical supports placed at a suitable distance apart. Running in bearings in the lower part of these supports is the shaft carrying the stationary roll of a shape similar to the interior of the channelled article to be formed. In the upper part of the supports are formed vertical slots, in which slots slide bearings carrying the spindle of the movable roll of a form similar to the back of the channelled article to be formed. Screwed spindles are attached to these sliding bearings by means of swivel joints, which pass through the upper part of the supports and carry suitable internally screwed worm-wheels actuated by means of a horizontal spindle running in bearings on the upper end of the supports and carrying worms. By means of the above arrangement, the upper roll can be raised to allow of the insertion of the end of the plate to be rolled, and then lowered and the rolls revolved in the ordinary manner, so drawing in and channelling the said plate. Claims: The manufacture of articles of channelled or trough-like sections from mild steel plates by rolling as described.—No. 20330. December 12th, 1890. 6*d*.

PRESSURE GAUGES.—*A. Lusuardi & A. Falco, both of Turin, Italy.*—The invention relates to the combination with a pressure (or vacuum) gauge of a counter capable of registering the variations of pressure above a given limit, and of preserving the indication of the sum of all these variations. In the annexed illustrations Fig. 1 is a rear elevation, Fig. 2 a vertical section, and Fig. 3 an elevation partly in section of a gauge constructed according to this invention. Within a box A is a pressure gauge tube B that operates by a link the needle C which indicates the pressure on a dial at the front of the apparatus. The pivot C^1 of this needle carries an arm C^2. When the pressure reaches the predetermined limit this arm C^2 comes into contact with a pin projecting from one end of a lever D mounted so as to turn with very little friction on the shaft of a ratchet-wheel E. A pawl F fixed to D engages the teeth of E and causes it to turn with the lever when the latter is moved by the arm C^2.

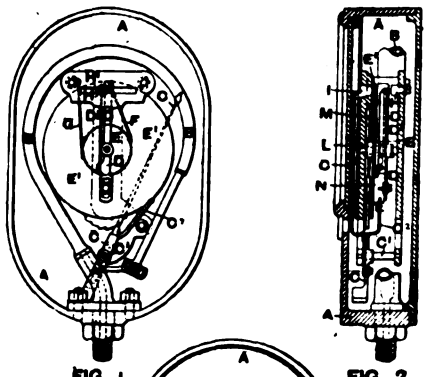

FIG. 1.

FIG. 2.

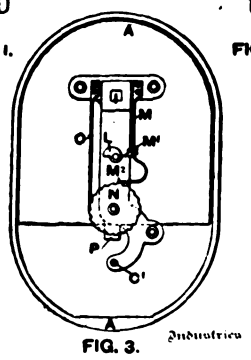

FIG. 3.

When D moves back F slides over the teeth of E which cannot turn backwards by reason of the detent G. The position of D, when the arm C^2 is not touching it, is regulated by means of the stop H, against which it is brought by the spring D^1. The stop H can slide in a slot H^1, within which it can be fixed at any desired point. The ratchet-wheel E is connected to a disc or dial E^1 that carries at its front side a graduated scale which can be observed or read off through an opening I (Figs. 2 and 3) in the dial of the pressure gauge. To register the revolutions of E^1 a cam L is fixed on the shaft thereof. This cam, at each revolution, operates one end of an elastic lever M, the opposite end M^2 moves a wheel N forward, one tooth of the wheel N being prevented from turning backward by a spring detent O. A graduated scale is fixed upon N to indicate the revolutions of E. Three claims are made.—No. 20792. December 27th, 1889. 8*d*.

MANUFACTURE OF SPIRAL SPRINGS.—*J. Melli, Hemishofen, Switzerland.*—The machine for producing springs of varied pitch is constructed in the following manner:—Two suitable metal plates are bolted together by means of two bolts, which also act as distance pieces to hold the two plates at a suitable distance apart. Sliding on these two bolts is a slide which is actuated by means of a screwed spindle running in bearings in the end plate and placed intermediate and parallel to the bolts. Through the slide are formed passages for the passage of the wire on to a second spindle, placed slightly above the screwed spindle, but which also passes through a lug fixed on to the upper portion of the slide. This second or core spindle is geared with the screwed spindle and revolves in an opposite direction thereto. The thread on the screwed spindle is broken up so as to form a series of short screws which are connected together by screw threads of less pitch. The slide is caused to follow the varied pitch of these screw threads by means of a set screw screwed into said slide and the end of which projects into and follows said screw thread. Three claims are made, embracing the machine for the manufacture of spiral springs of various pitch, substantially as described. —No. 20303. December 12th, 1890. 6*d*.

CRUSHING MACHINES.—*G. Norman, Sheffield.*—The machine is for crushing ore, quartz, road metal, and the like. In the annexed illustrations Fig. 1 is a side elevation with one side removed, and Fig. 2 a plan of a machine constructed according to this invention. A is the body or framework, in which is fitted fixed and rocking jaws E and C. The rocking jaw C is constructed with bearings to carry a roller B either bearing on its axis or against antifriction roller bearings at the back of it. The jaw is hung upon the axis D and is inclined towards E. At the back of the roller B is fixed the driving shaft F, carried in bearings and fitted with the usual driving pulley G and one or more fly-wheels H. Inside the body or frame A, and centrally on the shaft, is an

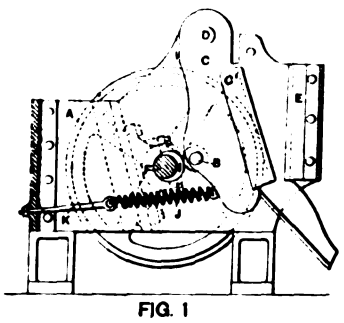

FIG. 1

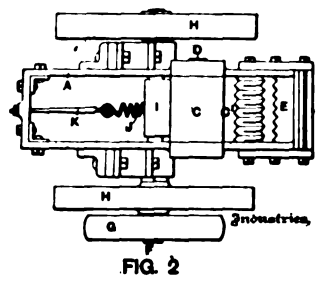

FIG. 2

eccentric or cam I, which corresponds in width with the roller B, the peripheries of both being brought in contact. The rocking jaw C is hung upon its axis so that after being forced forward it follows the receding movement of the eccentric by gravitation, but to render such return movement more certain a coiled spring J is used secured to the back of the jaw at one end and to the frame or body at the other end by means of a bolt K, so that the tension may be adjusted. Claims: (1) A crushing machine having a frame or body of convenient form, with fixed and rocking jaws E and C, the rocking jaw having a roller B for the purpose specified, a driving shaft with a cam or eccentric I to engage with the roller B, and with or without a coiled spring J, all the said parts arranged as shown; (2) in crushing machines for the purposes before specified, the arrangement of a direct acting eccentric or cam I, having its periphery in contact with a roller B carried by the rocking jaw, as described.—No. 3259. March 1st, 1890. 6*d*.

MIXING MACHINES.—*R. Hartmann, Dinglestadt, Germany.*—The invention relates to means in connection with the conveying granular or pulverulent substances under treatment in mixing machines. The device for this purpose consists of a hopper, the interior of which is divided into three parts, by means of two partitions disposed near to and parallel to two sides thereof. Revolving in slots in these partitions at suitable intervals in the depth thereof are the operating rollers, working in pairs, and being so placed that their peripheries project beyond both sides of the supplementary partitions into the central and side spaces of the hopper. Ranged in a direction coincident with the vertical axis of the hopper, and in its central division, are a series of bars of any suitable configuration in cross section, such as triangular. These bars run longitudinally and are parallel with the above-mentioned rolls, and serve as deflectors to assist in transporting to the rolls the granular or pulverulent substances fed into the top of the hopper of the mixing device. The rolls are geared together and operated so that each one of each pair revolves in an opposite direction to the other one of that pair. Claims: In a mixing machine of the type above specified, the combination with the pairs of rolls, the hopper with supplementary divisions of the deflecting bars placed centrally in the central division thereof, and means for imparting motion to the various parts of the apparatus as set forth.—No. 14769. September 18th, 1890. 6*d*.

ELECTRICITY.

INCANDESCENT LAMP-HOLDERS.—*J. W. Edmundson & W. Clarke, both of Gateshead-on-Tyne, Durham.*—The lamp-holder constructed according to this invention comprises two circular porcelain blocks, between which are secured four or more springs or prongs bent over the periphery of the lower block, and so shaped as to embrace the neck of the lamp, the grasp of these springs being aided by an elastic ring, such as a helical spring, embracing the outer ends thereof. The upper block is provided with a suitable cap, having in, and projecting from, its centre a hollow screw, by means of which it can be attached to a bracket or pendant, and through which passes the twin flexible connecting wire, the ends of which are connected to binding screws in the upper block. The two blocks are suitably bolted together, and have holes formed through them at diametrically opposite positions for the passage of the lamp wires to the terminals in the upper block. Claims: A holder for incandescent lamps, comprising two blocks of porcelain or other suitable material, perforated for the passage of the lamp wires, and holding between them spring arms shaped to embrace a lamp neck, and an elastic ring arranged to surround the spring arms and cause them to embrace and hold the lamp as described; the improved holder for incandescent lamps, substantially as described.—No. 993. January 20th, 1890. 8*d*.

ALTERNATE CURRENT TRANSFORMERS.—*G. Kapp, W. C. Johnson, & S. E. Phillips, all of London.*—The invention relates to transformers with a closed iron circuit. The core consists of a number of flat strips of iron, a number of which are placed side by side, but insulated from one another, so as to form a rod of square section, four of these rods being placed together, but insulated from one another, so as to form a bar of square cross section. Around this bar are wound alternately coils, forming the primary and secondary circuits. The ends of the core project beyond the coils, and have fixed to the upper and lower sides thereof the yoke or shell, consisting of rings of a suitable shape formed of thin band iron wound upon itself with strips of insulating material intervening between each layer. These yokes rest upon the core so that the edges of the layers of one rest on the edges of the layers of the other. Claims: In a transformer with a closed magnetic circuit—(1) the use of "yokes" made by winding a continuous strip of soft iron to a ring shape in combination with a straight core laid diametrically across the "yoke" rings, so that the surfaces of the core strips and yoke strips cross at right angles or nearly so; (2) in combination with "yoke" rings and core as above described, insulated copper wire coils surrounding the middle portion of the core and surrounded by the corresponding portion of the "yoke" rings; (3) the construction of transformers as described.—No. 3913. March 12th, 1890. 8*d*.

DYNAMOS.—*R. Kennedy, Kilmarnock, N.B.*—The invention relates to dynamos for producing alternating currents. Referring to the accompanying illustrations, Fig. 1 is an elevation of the polar end, Fig, 2 a side elevation of the complete apparatus, Fig. 3 being a second end elevation. The field magnets of the machine are energised by currents from a magneto machine without the use of a rectifying commutator in the exciting circuit. Referring to Fig. 1, A B is the permanent magnet field, built up of steel plates fixed by binding screws, C is the magneto armature wound in twelve sections, D E is the neutral line diameter of each coil, each coil reversing its induced current when passing same. The armature C of the dynamo, with coils C^1, wound on a Gramme ring armature, has twelve coils. The field magnet coils are connected each to a section of the magneto armature winding by wires G. The field magnet is enclosed by the fixed armature C, and is keyed on to the shaft H, as also is the magneto armature; the circular

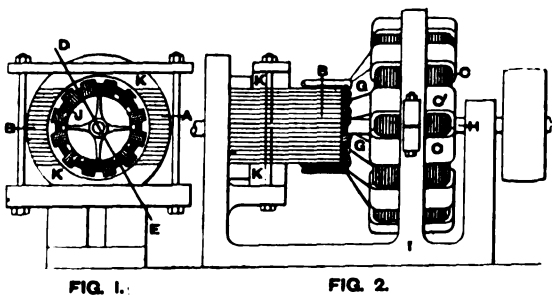

FIG. 1.

FIG. 2.

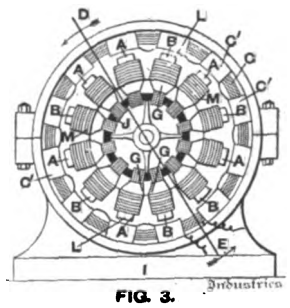

FIG. 3.

frame I binds the armature of the dynamo in place. The steel field magnets A B are of plates laid together to form semi-circular poles, embracing the armature J at one end, and being joined magnetically by an iron yoke of circular shape to fit the circle of the steel plates; these plates are bound by iron bolts and plates with wood packing pieces K (Figs. 1 and 2). In Fig. 3 is shown the arrangement of parts in elevation. The fixed dynamo armature C, with twelve generating coils C^1, is bound into the frame I. The field magnet L, with twelve radial poles A B, moves freely inside; the exciting coils M are each connected to a section on the magneto armature J by connecting wires G, to form the field magnet poles A B A B all round; the reversal of the exciting currents on the line D E produces alternately two S. poles and two N. poles, one on each side of this line, but the poles are maintained of the same polarity during their rotation from A to B and from B to A—that is, during a half revolution, so that they act inductively on the fixed coils C^1, and producing alternating currents therein. Three claims are made.—No. 18491. November 17th, 1890. 8*d*.

SECONDARY BATTERIES.—*H. H. Lake, London.* (*G. E. Hatch, Cambridge, Massachusetts, U.S.A.*).—The object of the invention is to construct a storage battery which shall have all the advantages of those batteries in which the peroxide of lead is held to the lead plates by perforating or forming projections on the latter,

Digitized by Google

and in which the thickness, and consequently the cost, of the lead plates may be considerably reduced. This the inventor accomplishes by using a stiff porous material, honeycombed or provided with holes, pits, grooves, or depressions, as separators and supporters of the metal plates, and in applying the active material of the battery to these porous plates instead of to the lead plates as hitherto. Claims: A storage battery, (1) having intermediate plates of stiff porous material alternately with its conducting plates; (2) consisting of alternate conducting plates of metal and intermediate plates of earthenware or similar material to which intermediate plates the active material of the battery is applied; (3) consisting of alternate conducting plates of metal and intermediate plates of earthenware, provided with recesses on either side thereof, and to which is applied the active material of the battery; (4) a separating and supporting plate composed of earthenware, and provided on either side with grooves, pits, or depressions, for the reception of the active material of the battery as described.—No. 19155. November 25th, 1890. 6*d*.

Semi-incandescent Lamps.—*F. R. Boardman, Manor Park Essex.*—The invention relates to semi-incandescent lamps, such as referred to in patents 1704 of 1880 and 10833 of 1887. In the annexed illustrations, Figs. 1 and 2 are respectively a vertical section and an elevation of a lamp intended for a series lamp and constructed according to this invention, and Fig. 3 is a vertical section of an automatic lighting and regulating gear. The block A is of marble and of a cylindrical shape, with three

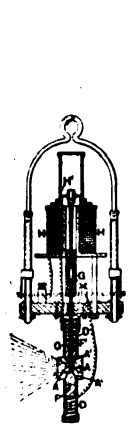

FIG. 1

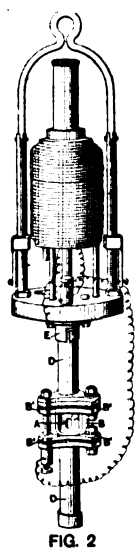

FIG. 2

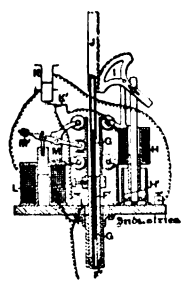

FIG. 3

conical openings formed symmetrically with one another, and a central hole A^1 for the carbons. This block is held in a circular box B (Fig. 2) similarly cut away, on the top and bottom flanges B^1, of which are bolted other flanges, the flanges being insulated from one another on the tubular holders D. A pin on one of these holders D engages with a bayonet joint E secured to the base of the lamp. Springs are placed in D to keep the carbon electrodes F F^1 up to their respective seats in A. The pencil carbon G for lighting lamp is automatically advanced or withdrawn through F^1 by means of one or more electromagnets as described in a prior patent No. 10833 of 1887. In the case of a lamp to be worked in parallel, and having the automatic gear above the block A (Fig. 3), three electromagnets are used. The lighting coil A is wound to form a resistance approximately equal to that of the refractory block A when incandescent, and its core extends below and fitted to form the piston of the dash-pot H^1. The core is also prolonged upwards and engages with a toothed sector I pivoted as shown, actuating a vertical rack J, to which the pencil carbon G is secured in any convenient manner, and by which it is advanced or withdrawn through the tubular carbon electrode F^1. When the current is switched on to the lighting coil H, the core of the latter is drawn upward, and so the pencil carbon G downward, until electrical contact is made between the carbons, and the current passes. At the same time the cut-out coil K has become energised by current passing through the same from the upper carbon-holder, and draws up its core, which is arranged by the cut-out K^1 to cut the lighting coil H out of the circuit. The weight of the core of the coil H draws the rack J and pencil carbon G upward, and the speed of withdrawal is controlled by the action of the dash-pot H^1, thus striking the arc, and lighting the lamp. In the event of the current becoming excessive the coil L comes into play, and its core caused to raise the carbon F^1 and its holder by the intervention of the lever M adjusted by counterweight M^1. The arc is so lengthened and the current reduced to its normal quantity, the opposite action taking place when the current becomes too small. Seven claims are made, embracing the apparatus as described, together with various modifications.—No. 3133. February 27th, 1890. 8*d*.

Wire Joints.—*C. H. McIntire, Newark, U.S.A.*—The object of the invention is to provide a joint of increased tensile strength for connecting telephone and telegraph wires, and for joining electric wires so that the conductivity of said wires is not obstructed. For this purpose the inventor uses a metal rod somewhat greater in width than in thickness, and of a suitable length. Longitudinally through this rod are formed two holes of a diameter equal to that of the wires to be joined, the holes being formed parallel to each other. Through these holes, at the opposite ends thereof, are passed the ends of the wires to be joined, the projecting ends being bent over. The cover, and so the wires, is then twisted, so giving the wires a better grip without interfering with the conductivity thereof. Claims: (1) A joint for uniting electric or other wires, consisting of a covering, having longitudinal perforations therein, into which the said wires are inserted oppositely, and said covering and the inserted wires twisted, as and for the purposes set forth; (2) a joint for uniting electric and other wires, consisting of a covering composed of two tubes soldered together, into which the said wires are inserted oppositely, and the covering and the inserted wires twisted spirally; (3) a covering for telegraph and other wires, having therein a series of separate bent or twisted passages, formed longitudinally to receive the ends of the wires for the purpose set forth.—No. 18117. November 11th, 1890. 6*d*.

Electrical Distributors.—*Siemens Brothers & Co., Limited, London.* (*A. M. Taylor, Baroda, India.*)—The invention relates to an automatic apparatus for compensating variations of current in conductors, a number of which are supplied from the same source, but proceed to different places. The apparatus for this purpose consists of a ring of soft iron, preferably made up of wire or laminæ, having wound on it several convolutions of each of the conductors to be compensated, the convolutions belonging to the several conductors occupying different parts of the circumference of the ring. Those of the conductors which have to convey electricity farthest have the fewest convolutions, and the others have the number of their convolutions properly proportioned according to their conditions, those which have the least resistance in their course having the greatest number of convolutions. As the currents pass through these coils, the ring is converted into a closed maguet, offering a back electromotive force to the current in each conductor, so that as the current in any one of these increases or diminishes, the currents in the whole will be proportionally increased or diminished. Claims: For automatically compensating variations of current in a number of electric conductors fed from the same source, a soft iron ring having wound on it separate coils forming parts of the several conductors, each having the numbers of its convolutions suitably proportioned as described.—No. 3841. March 11th, 1890. 6*d*.

Electric Meters.—*S. C. C. Currie, Philadelphia, U.S.A.*—The meters constructed according to this invention are for the purpose of measuring the strength of either direct or alternating currents, and are constructed as follows:—In a suitable casing are fixed two solenoids placed at a suitable distance apart and connected together and with the circuit the current passing through which it is desired to measure in series. Pivoted in plates fixed to each side of the casing and passing between these solenoids is a horizontal spindle, carrying at one end of it a suitable index finger arranged to move over a suitably graduated dial. Fixed about the centre of this spindle is an armature in the shape of a rod or bar of a compressed mixture of iron filings, chips, or shavings, and an insulating adhesive substance, as silicate of soda, or an analogous substance. A coil spring, one end of which is fixed to the index finger spindle, and the other end to one of the pivot plates, tends always to keep the pointer at zero on the graduated scale, and the armature in a position slightly at an angle to the plane of the winding of the solenoid when no current is passing, so that when the current is permitted to pass the armature will tend to set itself in a line with the axis of the solenoids, so moving the index finger along the dial, as is well understood. The inventor also describes a modification of the above-described apparatus in which the armature swings between the cores of two electromagnets, and is held, when no current is passing, in a nearly vertical position. Six claims are made.—No. 16653. October 20th, 1890. 6*d*.

CHEMISTRY.

Treatment of Scrap Tin or Terne Plates.—*W. P. Thompson, London.* (*E. Carez, Brussels, Belgium*).—The object of the inventor is to so clean the coating of tin off the iron of scrap tin or terne plates that the iron is fit for re-use. For this purpose the inventor uses either the sulphurets of sodium residues from the soda manufacture (Leblanc process) or the polysulphides of calcium mixed with hyposulphite of calcium transformed by means of carbonate of soda into sulphuret and hyposulphite of soda or of sulphurets of sodium mixed with a little nitrate of sodium, resulting from the manufacture of nitrate of barium by means of sulphide of barium and nitrate of barium or any other sulphuret of sodium more or less pure, and the sulphides, more or less sulphureted, are transformed into polysulphide by boiling them with a slight excess of sulphur. The polysulphide of sodium thus obtained is concentrated to about 30° Bé. in a vat heated by steam, and maintained at a temperature of 50°–70° C. for 2–3 hours. Chloride of ammonium is then added to this solution. The addition of this salt is necessitated by the solubility of sulphuret of iron in the polysulphide of sodium; it counteracts this dissolution and also any attacking of the metallic iron by the alkaline sulphide. The scrap tin plate is immersed in this solution for 3–4 minutes, and is then washed in water. The tin is given up in the form of sulphide of tin obtained by decanting the solution, and can be regained by the addition of a little hydrochloric acid. Claims: The process of treating and utilising scrap tinned iron by means of solution of alkaline polysulphide and chloride of ammonium, and separating the tin as a sulpho-stannate or sulphide as described.—No. 1913. February 5th, 1890. 6*d*.

Production of Aluminium.—*G. Shenton, London.* (*M. J. Berg, Paris, France*).—The inventor effects the above object in the following manner:—A mixture of coke dust or charcoal dust, nitrate of soda or potash, and a substance containing alumina, such as cryolite, bauxite, websterite, sulphate of alumina, crude clay or brick dust, in a finely pulverised state, are placed in a plumbago crucible between two carbon electrodes. Through this mixture an electric current of a tension of 20–50 volts, and an intensity of 1,000–10,000 amperes is caused to pass. The presence of the carbon dust renders the charge conductive, the aluminiferous substances melt, and metallic aluminium is deposited at the negative pole and remains melted, its presence in the liquid condition acting as an accumulator of heat. At the same time the foreign metals and the silica resulting from the employment of clay or bricks are burned by the nitrates and disappear in the state of oxides. Three claims are made, embracing the process as described with modifications.—No. 2002. February 6th, 1890. 6*d*.

Manufacture of Steel.—*W. P. Thompson, London.* (*M. F. Coomes & A. W. Hyde, both of Louisville, Kentucky State, U.S.A.*).—The object of the inventors is to carburise malleable cast iron and steel having a low percentage of carbon, and thereby convert them into a steel having a high percentage of carbon. For this purpose the inventors use a bath composed of the following ingredients:—First, a saturated solution of chloride of sodium is made; second, to this solution is added sugar up to saturation point, and then to this double saturated solution is added chloride of ammonium until it will hold no more. For carburising, the metal is plunged into this triple saturated solution at a white heat, but for tempering only at a dull cherry-red heat. Claims: (1) In the manufacture of steel the process of carburising malleable cast iron and low carbon steel consisting in placing metal raised to a white heat in a bath composed of water, sugar, chloride of sodium, and chloride of ammonium, as described; (2) as a tempering and carburising bath, the triple saturated solution of water, sugar, or other similar saccharine substance, chloride of sodium, and chloride of ammonium, substantially as described.—No. 18171. November 11th, 1890. 4*d*.

Reduction of Metallic Ores.—*G. Simonin, Libourne, France.*—The invention relates to a method of the reduction of ores by roasting more especially applicable to the treatment of the ores of antimony and zinc. For the purpose of reducing the sulphides, carbonates, and other metallic compounds of these ores to oxides the inventor employs a revolving reverberatory furnace. The ores are treated in such revolving furnaces until roasted or oxidised, and in some cases the oxides may be carried over and condensed or deposited in suitable chambers. The ores may, if desired, be treated with reducing agents whilst in the revolving furnace. Claims: (1) The treatment of metallic ores in a revolving reverberatory furnace as described; (2) the process of the treatment of the ores of zinc and antimony with the aid of a revolving reverberatory furnace as described; (3) the reduction of the ores of zinc and antimony in a revolving reverberatory gas furnace and the recovery of the volatilised oxides, substantially as described.—No. 3275. March 1st, 1890. 4*d*.

MISCELLANEOUS.

Manufacture of Cast Iron.—*J. B. Renshaw, Hartford, Connecticut, U.S.A.*—The inventor treats grey iron, for the purpose of eliminating surplus graphitic carbon and a substance called "kish," in the following manner:—Iron oxide in a pulverised form, and sawdust, shavings, straw, or other vegetable fibre, are mixed together, the latter substance having been previously saturated with water in the proportion of about 3lb. water to 1lb. fibre. The whole is then dried, and preferably packed in paper bags until used. When it is desired to eliminate graphitic carbon from molten iron a suitable amount of the above mixture is placed upon the iron before melted, or in the iron when melted, or in a ladle into which the melted iron is to be poured, the proportion of the mixture used being about 3lb. to every 100lb. of iron. The action of the mixture is as follows:—As the fibre burns, the oxide is released in separate particles by the action of the heat, and the oxygen in the iron oxide mixes with a corresponding quantity of the graphitic carbon in the iron, so forming carbonic acid gas, which escapes into the air. Claims: The process of eliminating graphitic carbon or "kish" from melted iron, by means of iron oxide, which consists in first mixing vegetable fibre, or its equivalent, with pulverised iron oxide, and then adding the compound to the iron to be melted, or being melted, or previously melted, as described.—No. 16724. October 21st, 1890. 4*d*.

Substitute for Fire-clay.—*J. Lever, J. Holland, & W. H. Todd, all of Manchester.*—The material is for use in steam boiler and other furnaces for burning smoke as a substitute for fire-clay and other refractory materials hitherto used. For this purpose the inventors use alumina or hydrate of alumina in as pure a state as can be economically obtained. This material is pressed first into moulds of a suitable shape, and then heated to incandescence for two or three hours, whereby the alumina sets or becomes more or less hard. The object of using moulds is to keep the alumina in the required shape until the action of the heat of the furnace fire causes it to harden. Claims: The use of alumina or hydrate of alumina as the material for the manufacture of appliances for burning smoke in steam boiler furnaces.—No. 3676. March 7th, 1890. 4*d*.

Manufacture of Coated Aluminum Plates.—*W. P. Thompson, London.* (*C. H. Land, Detroit, Michigan State, U.S.A.*).—This invention has for its object the manufacture of a compound aluminum plate which can be united, under the application of heat, to other metal plates. This the inventor does by coating the aluminum with tin by immersing the former in the latter in a molten state and rubbing the surface of the former whilst so held. The aluminum thus receives a thin coating of tin upon its surface, to which any other metals, such as copper, brass, galvanised iron, &c., formed into plates, and having a coat of tin adhering to their surface, can be joined by pressing the tinned surface of the aluminum plates and that of the other metal plate together under the application of heat. Claims: (1) A compound metallic plate or other metallic body consisting of aluminum provided with a tinned surface; (2) the process, as set forth, of manufacturing a compound aluminum plate or other body provided with a tinned surface consisting in burnishing tin upon a surface of the aluminum at a desired temperature; (3) the process of attaching aluminum facings to various surfaces consisting of tinning the face of the aluminum in the manner described, and attaching the same to the said surface as set forth.—No. 18915. November 21st, 1890. 6*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

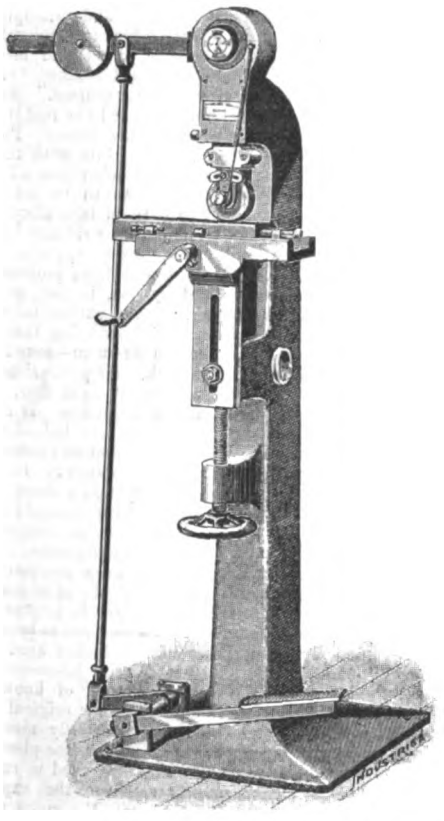
THE "INVINCIBLE" THREE-CYLINDER SAND PAPERING MACHINE.



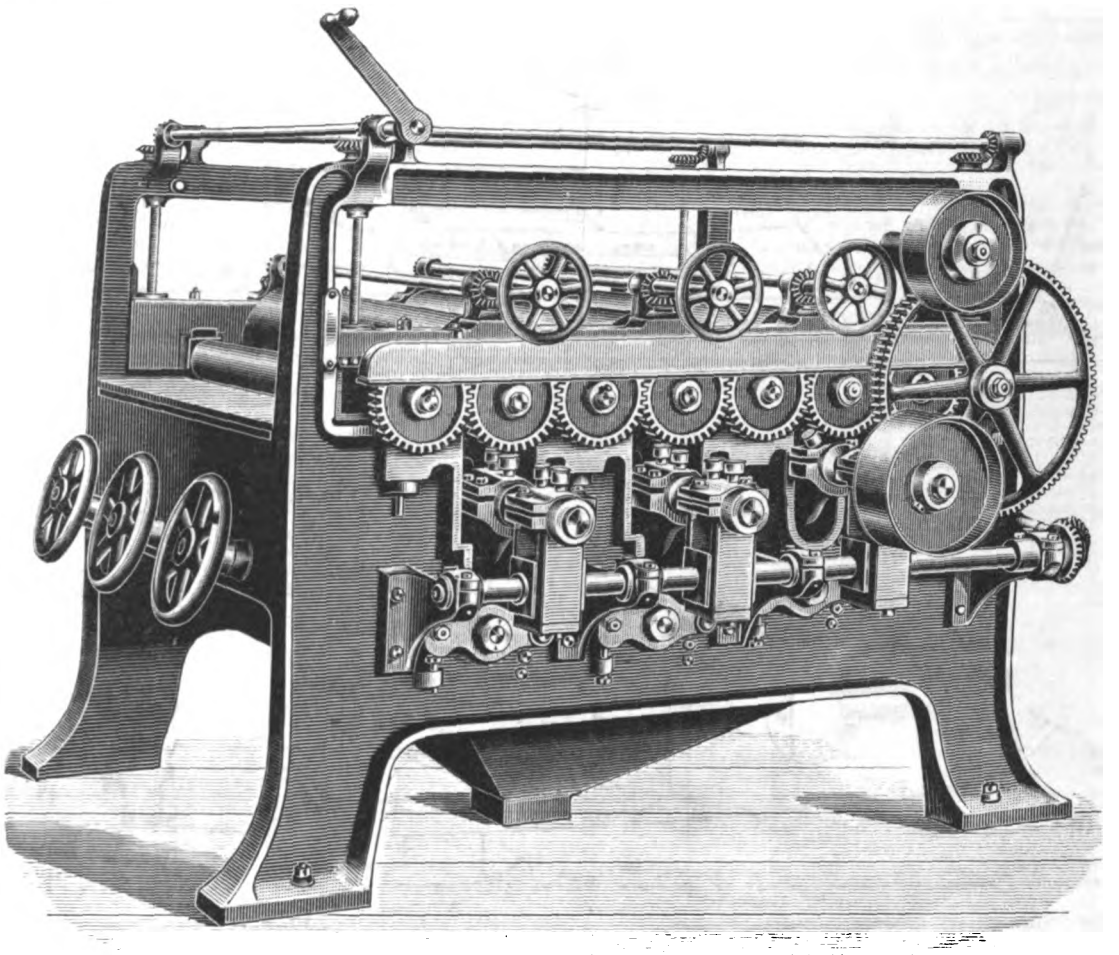
For some time Messrs. Thomas Robinson & Son, Limited, Rochdale, have been giving their attention to machinery for sand-papering and polishing woodwork. The want of really efficient machinery of this kind has long been felt. The machine we now illustrate is the latest improvement in machinery of this type. It embodies several new features which have been suggested by practical working, and gives results as near perfection as can be generally wished. The machine has three sand papering cylinders. The first is covered with a coarse grade of paper, and has a cutting action on the wood similar to that of revolving cutters. When operating on framed work for doors or parquetry, it will cut away all the uneven surfaces without breaking away the edges or plucking the cross-grained parts, and leaves an even surface for polishing. The second cylinder is covered with a somewhat finer paper for sand-papering. The third cylinder is for finishing the work. It has a very soft fine cushion for the paper, which just touches the work, and imparts to it a very high polish.

Each cylinder is independently adjustable—either when running or standing—to any desired cut, by simply turning the hand-wheels shown at the front of the machine. In fastening the paper to the cylinders screws and bolts are entirely dispensed with. A simple and positive device is used, which holds the paper with great firmness, and which also takes up the stretch which occurs in the paper. With this arrangement the paper can be put on in one-third the time formerly required, and it is said to effect a saving of 25 per cent. in paper. Each drum is made to oscillate by means of an ingenious crank motion, so constructed that it has no lost motion or wear, and consequently causes no jar or tremor to the machine.

Messrs. Thomas Robinson & Son, Limited, are now constructing a special machine of this type for door finishing. This machine is 5ft. wide, and will allow the largest doors to be passed through the machine diagonally, thus enabling the cross rails and all parts of the framing to be polished with the most perfect finish.

AN IMPROVED METAL MARKING MACHINE.

The accompanying illustration, for which we are indebted to our American contemporary the *Iron Age*, represents the Dwight marking machine. This machine is adapted, by means of steel dies, to impress on flat or



round finished metal surfaces letters, numbers, trade-marks, &c. The die holder is held in the lower end of a square slide, the upper end of which is connected to an eccentric or cam shaft. To the cam shaft the weighted arm is keyed, which, as shown, is further connected with the foot lever. On the front end of the die shaft a groove is turned, in which one end of a cord connected with a light spring is wound up as the die is doing its work. When contact of die and work is broken, the shaft and die are revolved by the tension of the spring until a fixed pin in the shaft comes in contact with a pin in an adjustable washer. This washer, which fits on the shaft and is held in position by a circular slot and set screw, is shown in the illustration. The adjustment secured by this washer and pin enables the operator, when setting up the machine, to bring the character on the die which should strike the work—first to a position at right angles with the face of the work, and afterwards ensures its returning there after each impression by means of the spring. The work to be marked is fixed on the sliding table, which is moved by a rack, pinion, and crank under the die. The travel of the table is regulated by a projecting dog and the two adjusting screws shown, which should be so set as to stop the movement of the table as soon as the die has revolved far enough to bring the last character to a position of full impression.

The die and slide, when standing at their normal height, are at their lowest position, and the office of the foot lever is to raise the die so that work can be inserted. The position of the weight on the arm determines the amount of impression when the work varies in thickness. When work is got out to uniform thickness, a set screw that will regulate the drop of the weighted arm is provided, and the impression can be sunk to an exact depth each time. When the work varies in thickness, the impression will depend on the adjustment of the weight. When marking round work, such as reamers, taps, &c., a flat die is used, the work being placed against a little angle piece to ensure its resting at right angles with the die; the die is brought in contact with the work and the table given a movement that causes the work to revolve. This method of using the dies requires but comparatively little pressure, and hollow tubes, valve bodies, &c., can be marked without danger of springing. The extreme travel of the table is 6in., and the distance from the centre of the die to the frame is 3½in.

The machine is made by the Dwight Slate Machine Company, of Hartford, Conn., U.S.A.

THE "INVINCIBLE" THREE-CYLINDER SAND PAPERING MACHINE.

Constructed by Messrs. Thomas Robinson & Son, Limited, Rochdale.

General View.

THE DUTCH GOVERNMENT WARSHIP "PRINSES WILHELMINA."

The illustrations, Figs. 1, 2, and 3, on page 194, represent, in elevation, plan, and cross-section, the projected design for a new turret ship of the above name for the Dutch Navy. This vessel, now in construction, is a steel unarmoured twin screw, with a protective deck and a ram bow. The length over all is 330ft.; moulded breadth, 49ft.; depth from underside of keel to top of upper-deck beam, 29ft.; displacement to load water line, with 450 tons of coal on board, 4,600 tons; greatest draught at that displacement, 19ft. 6in. The protective deck extends over the whole length of the vessel, from the round stern to the stem, and is 16in. above water in the centre and 3ft. 6in. below water at the sides, and gives protection to the vital parts of the ship. The mid part of the ship is double-bottomed. Between the protective and 'tween-deck a cellular arrangement is adopted. The cellular belt, with a breadth of 2ft. 6in. in the midship section, is filled with cellulose. There are ten watertight bulkheads below the protective deck, and seven above it, all cross bulkheads. The engine-room is divided in two parts by a watertight bulkhead running fore and aft. The armament consists of one 28-centimetre breech-loading No. 2 gun, of 30 kilos., placed forward, with a train from ahead to 150° at both sides, fitted in a revolving turret. A 21-centimetre breech-loading pivoted gun of 35 kilos. is placed aft, with a train of 148° from astern to both sides. Two 17-centimetre breech-loading guns, with centre pivot, and 35 kilos. long, are placed at both sides of the ship, with a complete broadside train, firing also from right forward to right abaft. Six revolving cannons and eight rapid-fire guns of 3·7 centimetres are disposed on the hurricane deck and in the military tops. Two torpedo-launching tubes are on the 'tween-deck in the sides of the ship, each having a train from broadside to 17° forward and 70° aft. Another torpedo tube is fitted in the stern. All torpedoes are launched above water. The turret is protected by com-

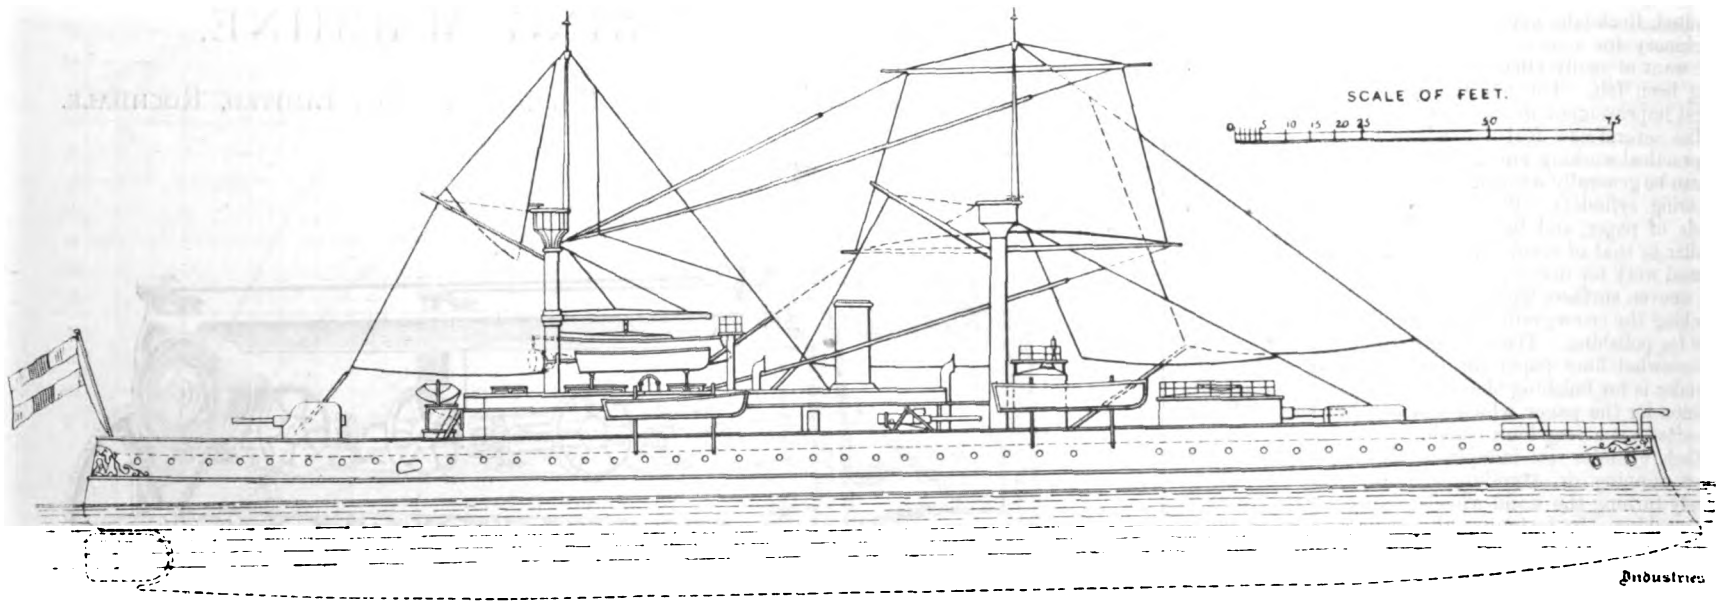

FIG. 1.—ELEVATION.

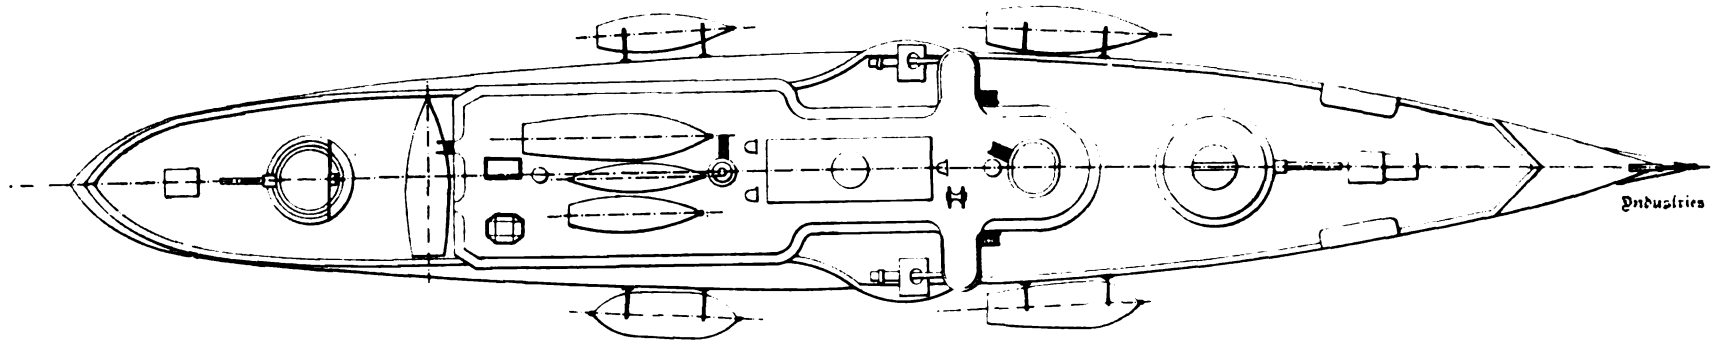

FIG. 2.—PLAN.

pound armour-plates of 28 centimetres with a 22-centimetre teak backing, and covered with a steel cover of 38 millimetres. It can be turned round in 45 seconds by hand and steam motion. A conning tower, armoured with 28-centimetre compound plates, is placed forward, and fitted with all the apparatus necessary for steering, telegraphing, turret, and gun-motion. As the conning tower is located on the central superstructure of the ship, an armoured tube, 28 centimetres thick, runs from this tower to the protective deck, to protect the steering gear and speaking tubes. The ship is lighted throughout by electricity, and is also provided with two electric search lights.

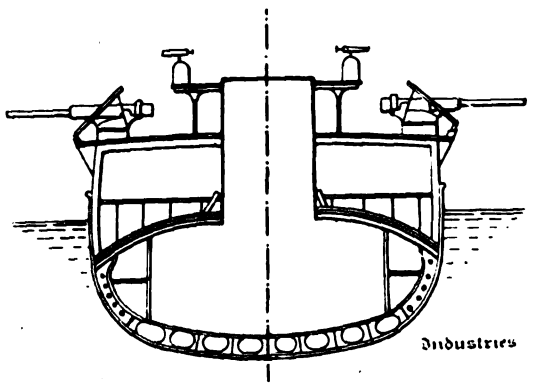

FIG. 3.—CROSS SECTION.

The hull of the ship is made of steel, the stem and stern posts of manganese bronze. The brackets for the propeller shafts and the rudder frame are also of manganese bronze. The armour, or protective deck, slopes fore and aft and to the sides. The top is flat and 2in. thick, the slope being 3in. The whole deck is constructed of steel plates 1in. thick, so arranged that one layer forms edge strips and butt straps for the other. The casings above the engine and boiler room are protected with compound armour plates. All watertight doors in the bulkheads below the armoured deck are to be handled from the upper deck and from the 'tween-deck. As will be seen, the vessel is rigged with two masts with military tops, provided inside with clamps and apparatus for hoisting ammunition. Each mast has a wooden topmast. The foremast has two yards with a topsail. The vessel is provided with two separate pairs of vertical triple-expansion engines, one of each pair of which is capable of driving one of the propellers, and is constructed to work with or without condensers. It is estimated that one pair of these engines will have a capacity of 5,000 horse-power, with a pressure of air in the boiler rooms equal to a 5-centimetre column of water. The diameters of the cylinders are respectively 19in., 31in., and 51in., the stroke is 27in., and the number of revolutions about 170. The four condensers are cylindrical, with a total cooling surface of about 8,000 square feet. The shafts are of steel. The propellers are four-bladed, of delta metal, with a diameter of 11ft. and a variable pitch from 11ft. to 14ft. There are four cylindrical return tubular boilers of steel, made to withstand a pressure of 170lb. per square inch. The furnaces are to be made of Purves' corrugated flues. The estimated speed is 16½ miles per hour, with 4,400 tons displacement. The number of the crew is 325. The stores provide for a ten weeks' cruise, whilst 32,000 litres of fresh water are to be carried. We are indebted for the illustrations and description to *Marineblad*.

THE UNIVERSITY TRAINING OF ENGINEERS.*

(*Concluded from page* 171.)

I CONCEIVE that one of our first aims in furthering the advancement of the School of Engineering in Cambridge should be to secure the establishment of an Engineering Laboratory. I have the satisfaction of knowing that this was Professor Stuart's wish, as it is mine. It may not be out of place, then, to give a brief account of the character and uses of an engineering laboratory. If its inception is mainly due, in one sense, to the enthusiasm of a single teacher, in another it is essentially a product of the time. It is the application to engineering of an idea that has permeated all our higher teaching of science—the idea that the student must be brought face to face with *things*. There is nowadays no need—least of all is there any need in modern Cambridge—to eulogise laboratory training, to tell how it stimulates interest, how it fosters exactness, how it creates habits of observation and of independent thought, how it makes the dry bones of a science start into life. Facts and principles learnt from the text-book or the lecture-table are colourless and dull: in the laboratory they become vivid and memorable. "We study nature in books," says a great teacher, "and when we meet her face to face she passes unrecognised." Study her in books we must, but if our knowledge is to be real it must be of the kind that a face-to-face acquaintance brings. Put a good student into a laboratory, and you inspire him with the enthusiasm of the investigator; put a good teacher into a laboratory and you ensure that he will never cease to be student. In regard to engineering the rapid growth of laboratory teaching is itself fair evidence of its value: if other evidence be wanted it will be found in the uniform chorus of approval which is heard alike from academic teachers and from professional engineers. The engineering laboratory has, in fact, gone far to bridge whatever gulf may be said to have existed between professors and practitioners. It teaches something that is learnt neither in the workshop nor in the lecture-room—something that connects the knowledge gained in both. Its professional utility is great; but more than that, and apart from that, it claims your attention as a genuine means of education. It has found a place in the great continental schools, where, indeed, it existed, though only as a means of research, even before Professor Kennedy gave it form as an educational appliance. In America, where the initiative was independently taken about the same time by Professor Thurston, there are now several fine laboratories, among which that of the Massachusetts Institute is distinguished by its great extent and lavish equipment.

The objects of an engineering laboratory are threefold. It gives the student practice in those kinds of experimental work which he may afterwards have to perform in professional life. Further, it teaches him how investigations are to be conducted, and gives him some experience in this higher kind of work. And lastly it endeavours, as all university laboratories endeavour, to contribute to the common stock of knowledge by furnishing opportunities and appliances for original research. The work which is done in it is essentially measurement. Measurement of the strength, the elasticity, the plasticity, and other properties of the materials that are used in engineering construction—such measurements as form the experimental foundation of the theory of structures. Measurements of the power of prime movers: measurements of "efficiency"—of the relation, for example, between the heat that is supplied to a steam engine and the work that is done; measurements of friction, and the losses of energy that proceed from it, of the accuracy of apparatus, of hydraulic constants, and a host of other things which it would only weary you to have me enumerate. The work trenches, to some extent, on the work of a physical laboratory; but even where it is most like that in general character the work of the engineering laboratory is done

* Abstract of an introductory lecture delivered at Cambridge on the 20th ult. by Professor J. A. Ewing, F.R.S.

Digitized by Google

with a somewhat different intention and on a larger scale. To carry it out with anything like fulness requires the provision of costly plant; some of it may, however, be done with rough and inexpensive appliances. We may, at least, make a beginning with them at once, and it is my hope to do so, but in doing that I trust I shall be acquitted of any intention to rest content until a laboratory is provided that will be worthy of the University of Cambridge.

In the existing workshops we have a nucleus about which a laboratory may very naturally grow. Whether a university school of engineering ought or ought not to give its students any systematic instruction in the manual processes of the workshop is a question in regard to which experts are by no means agreed. On one hand it is urged that the college workshop is necessarily small, that practice in it cannot (and this all will admit) entirely take the place of pupilage in a manufacturing establishment; that time for it can be ill spared from the more necessary parts of the curriculum, and that the pupil will have a better opportunity of learning the same things in his subsequent experience at the works. On the other hand it may fairly be pleaded that if the subsequent apprenticeship is to be shortened—as we contend it may—the pupil will do well to learn what he can of the use of tools during his college course; that much that is useful *can* be effectively taught even in a small way; that the workshops gratify a healthy instinct and that the time spent in them is an agreeable recreation in the midst of severer studies; that some acquaintance with the ordinary mechanical operations is of service even in the earliest stages of college training; that the workshops are of benefit to students who do not mean to be engineers—a consideration of special weight in Cambridge; and, above all, that a workshop forms a most important adjunct to an engineering laboratory. In any case, it seems to me that the question of the workshops is no more than a detail, and perhaps not even a very important detail, in a much larger question. The larger question is how are we to secure anything like a fully-organised school of engineering?

The engineering school must be accepted as an integral part of the University system. The work done in my department must be closely interlinked with that done in other departments; the teaching of applied mechanics must go hand-in-hand with the teaching of mathematics, physics, chemistry; the students of engineering must receive such academic encouragement as will attract the best men. What precise form the recognition of engineering should take, in your scheme of examinations, it is not for me at present to suggest (I must first learn the alphabet of your language), but even a very slight knowledge of the matter is enough to show that the recognition now given is far from adequate. For the subject of applied mechanics I claim no more than is due to its intrinsic importance and its educational value as a field of scientific thought—apart from its professional uses; but in claiming that I claim the warmest possible welcome for my subject at the hands of the University. At Victoria University an honours degree is conferred in the department of engineering, and I venture to say, after having been examiner there for three years, that no one who will acquaint himself with the style and scope of the course there pursued can doubt that the subject is worthy of a place among university studies and of all the support that academic recognition can give. Applied mechanics does not now knock at the doors of the universities, supplicating admission. The question is not whether a school of engineering is a legitimate part of a university, but whether a university is reasonably complete without a school of engineering. And at the risk of repetition let me add that a school of engineering does not mean an isolated professorship. We must have a department working in the closest association with collegiate tuition and other spheres of University activity, amply furnished in respect of buildings and plant, secure of University favour, and forming an accepted avenue to University distinction. The student who comes here with the serious intention to study engineering must be prepared to follow, and we must be prepared to find for him, a connected course carefully planned to be at once educative and professionally useful, which will engage his full attention during the usual period of academic residence.

Engineering, with the sciences that bear upon it, forms so large a subject that if the course is to be complete it must be engrossing. The student must, in a sense specialise from the very first. His course should comprise mathematics, mechanics, chemistry, and physics—especially heat and electricity—the strength of materials, the theory of structures, the theory of the steam engine and other prime movers, the theory of mechanism, hydraulics, surveying and levelling, practical geometry, and engineering drawing. In several of these subjects the work of the lecture-room must be supplemented by work in the drawing-office, the laboratory, the workshop, and the field—work that exacts no little time and attention. To enable him to pursue such a course the student may fairly ask for the freedom that is allowed to the specialists of the triposes: and having pursued it he will not be denied some claim to a degree. Without an organised engineering school, Cambridge must lose many good men who intend to be engineers, who forego the benefits of University residence and the unrivalled advantages which this University offers to mathematical students, in order to seek elsewhere the special training their profession demands. The schools of mathematics, physics, and chemistry will profit by association with a school of engineering. And again, among the men of mathematical bent who in any case would come to Cambridge there must be a few whom an engineering school would draw into a congenial profession which they otherwise would miss.

There is still another aspect of the matter, too important to be passed without brief mention. Apart from its service to professional students, an engineering school has work to do in the training of those whose business in life will be to teach Applied Mechanics. This is a career that now gives occupation to a very great number of men in the colleges, in the technical schools, in the numerous classes that are conducted in all industrial centres under the auspices of the Department of Science and Art. The training of these teachers is a work of national importance in which the University of Cambridge may surely take a share. When a college or a school wants a professor or teacher of mathematics or physics it turns to Cambridge. The same thing holds good, to an increasing extent, of the natural sciences. It appears, however, that the University goes beyond its bounds to find even its own professor of engineering. I, for one, have no reason to regret the fact; but is it too much to hope that in time the Cambridge graduate may become as acceptable a teacher in this subject as in others?

The introductory address of a Professor of Engineering would be incomplete if it did not conclude with the cry of the horse-leech. I address the cry of "Give, Give," not only to those whose business it is to sit upon the lid of the University Chest, but to all friends of Cambridge, to all friends of engineering education. Is the school of engineering at Cambridge to be as complete, as well furnished as any existing school? Where are we to look for the £10,000, the £20,000, which has supplied the wants of Manchester, of Leeds, of Liverpool? I was cheered to read in the address of the Vice-Chancellor to the Senate his expression of belief that, should the establishment of an engineering laboratory be held to be in itself desirable, pecuniary help from non-resident as well as resident friends of the University was not likely to be refused. I appeal for that help earnestly and confidently, convinced that a laboratory is not simply desirable, but indispensable.

ROPE DRIVING.

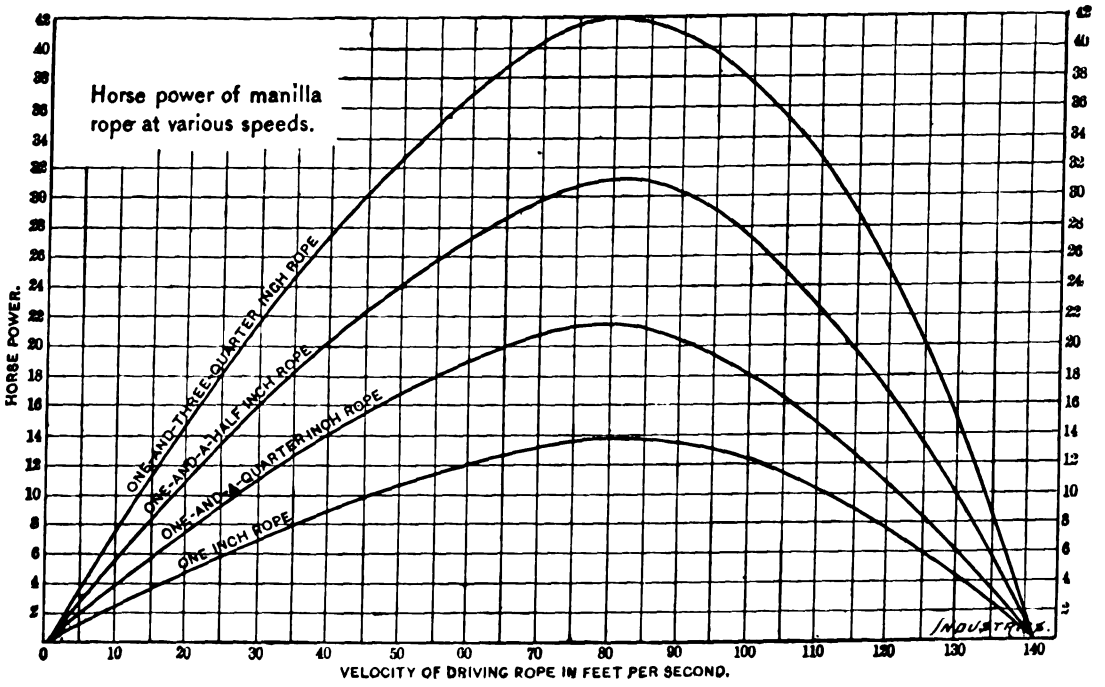

FIG. 1.

ROPE DRIVING.*

THE transmission of power by cotton or manilla ropes was a few years ago an experiment. It passed the experimental stage, and its use has spread with remarkable rapidity, both in England and the United States, and promises, at the present rate of increase, to become a formidable competitor with gearing and leather belting for use where the amount of power is large or the distance between the power and the work is comparatively great. The most prominent questions which the engineer who proposes to make an application of rope driving wishes to have answered are those relating to the horse-power, wear of rope, first cost of rope, and catenary.

These questions cannot be answered with precision in a general essay, but it is the purpose of this paper to give the general limitation of this method of transmitting energy in order that an engineer may make a close approximation, and then, in the case of a large installation, make such supplementary calculations as the importance of the case demands. It will be assumed that the conditions are favourable to this mode of driving, leaving abnormal cases for such special treatment as the engineer may at the time think best to use. The subject is so new that but few accurate data are available, arising from the long period required in each experiment, a rope lasting from three to six years. In many of the early applications so great a strain was put upon the rope that the wear was rapid, and success only came when the work required of the rope was greatly reduced. The strain upon the rope has been decreased until it is approximately known what it should be to secure reasonable durability. Installations which have been successful, as well as those in which the wear of the rope was destructive, indicate that 200lb. on a rope 1in. in diameter is a safe and economical working load. When the load is materially increased, the wear is rapid. For the purpose of this paper, this load of 200lb. for the normal fibre stress of a manilla rope 1in. in diameter will be assumed to be the one which it is advisable to use, and the horse-power and relative wear at different speeds will be estimated. Farther experience may modify this assumption, but at the present time it is the best obtainable, and the changes which may be made hereafter will affect but slightly the estimates here given.

To ascertain the average breaking strength of commercial rope, I lately purchased four pieces made by different cordage works, and had them tested on the Fairbanks testing machine in New York. They varied slightly in diameter, but when reduced to the equivalent of a rope 1in. in diameter, had an average breaking strength of 7,140lb. Expressed algebraically, the breaking strength, weight per foot, and the working strains are—

$$W = 720\,C^2\,(1);\quad P = \cdot 32\,C^2\,(2);\quad w = 20\,C^2\,(1)$$

in these and the following equations:—

C = Circumference of rope in inches.
D = Sag of the rope in inches.
F = Centrifugal force in pounds.
g = Gravity.
H = Horse-power.
L = Distance between pulleys in feet.
P = Pounds per foot of rope.
R = Force in pounds doing useful work.
S = Load in pounds on rope at pulley.
T = Tension in pounds of driving side of the rope.
t = Tension in pounds on slack side of the rope.
v = Velocity of the rope in feet per second.
w = Working load in pounds.
W = Ultimate breaking load in pounds.

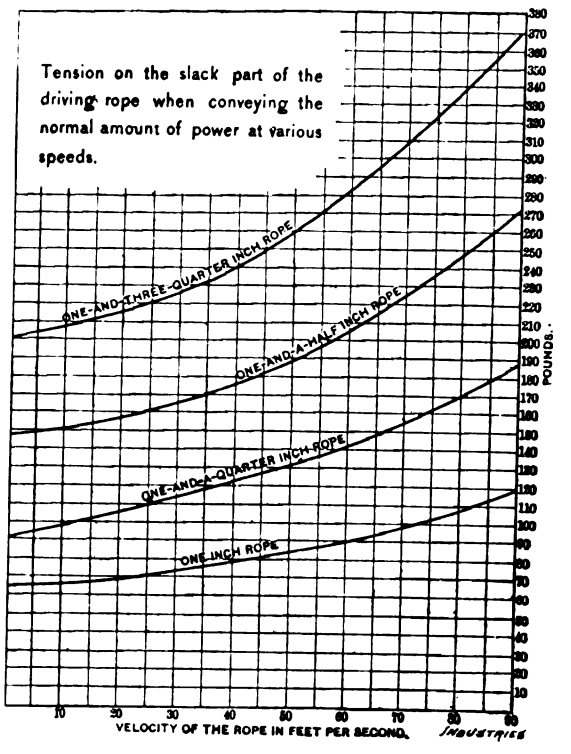

FIG. 2.

This makes the normal working load equal to one-thirty-sixth of the breaking strength and about one-twenty-fifth of the strength at the splice. The actual loads are ordinarily much greater, owing to the vibrations in running, as well as from imperfectly adjusted tension mechanism.

We will assume that the load on the driving side of a rope is equal to 200lb. on a rope 1in. in diameter, and that the rope is in motion at various velocities of from 10ft. to 140ft. per second. Under this assumption, we will have in all cases a fibre load of 200lb. on the driving side of a 1in. rope, and an equivalent load for other sizes. The centrifugal force of the rope in running over the pulley will reduce the amount of force available

* Abstract of a paper read at the Richmond meeting of the American Society of Mechanical Engineers, by Mr. Chas. W. Hunt, of New York. We are indebted for the illustrations to our American contemporary, the *Engineering and Mining Journal*.

THE OLSEN TESTING MACHINE.

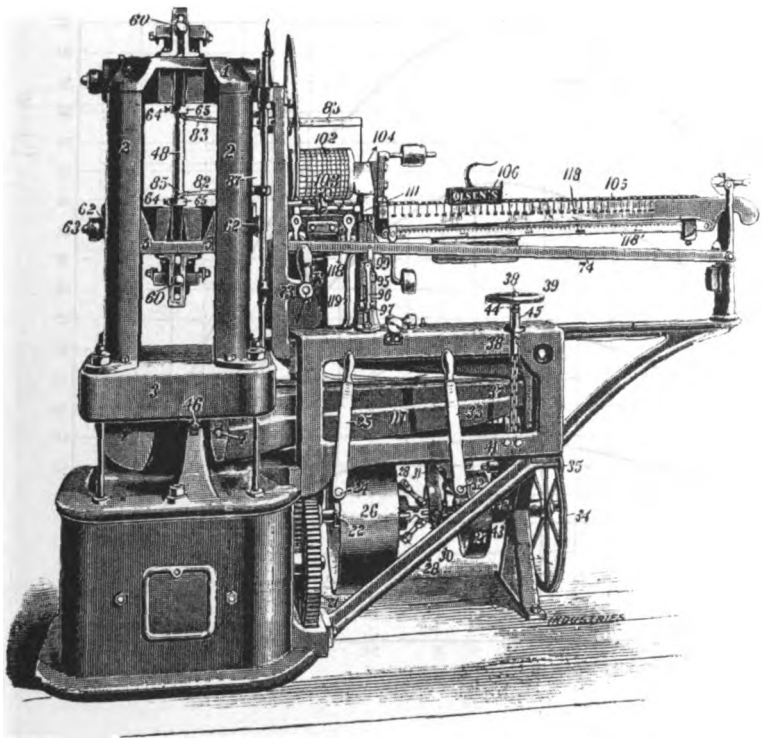

FIG. 1.

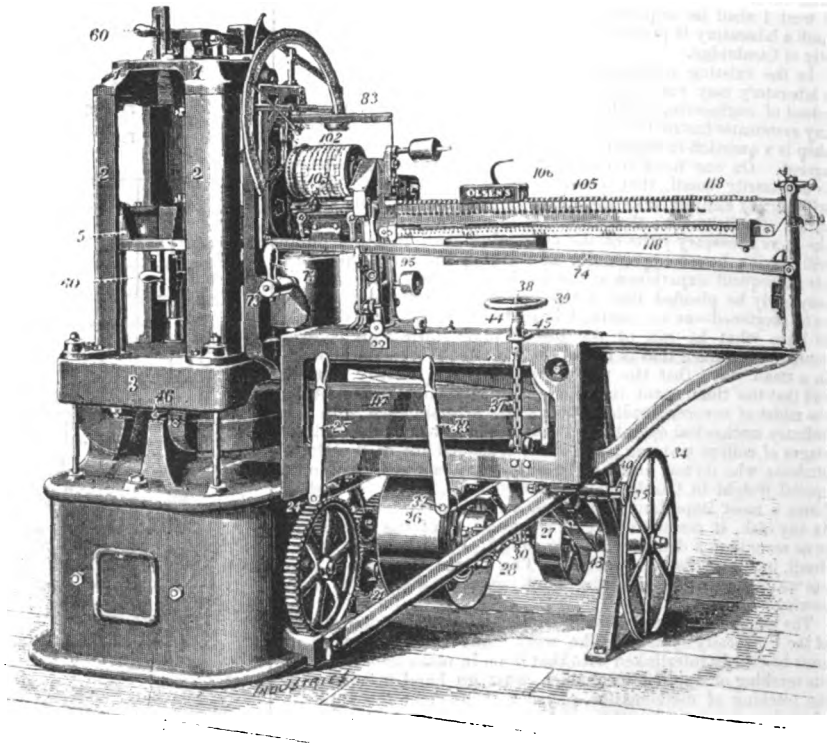

FIG. 2.

for the transmission of power. The centrifugal force of the rope is computed by the formula—

$$F = \frac{P\,r^2}{g}. \qquad (2)$$

At a speed of about 80ft. per second, the centrifugal force increases faster than the power from increased velocity of the rope, and about 140ft. per second equals the assumed allowable tension of the rope. Computing this force at various speeds and then subtracting it from the assumed maximum tension, we have the force available for the transmission of power. The whole of this force cannot be used, because a certain amount of tension on the slack side of the rope is needed to give adhesion to the pulley. What tension should be given to the rope for this purpose is uncertain, as there are no experiments which give accurate data, and at the present time a decision must be made partly from analogy and partly from experience.

If the rope be considered as a belt on a plain pulley, the friction would be substantially the same as a leather belt at the same tension; but as ropes are frequently lubricated to reduce the wear, the coefficient of friction must be materially reduced. There have been no experiments to decide with accuracy what this reduction is, but it is known from considerable experience that when the rope runs in a groove whose sides are inclined toward each other at an angle of 45° there is sufficient adhesion when the ratio of the tension is

$$\frac{T}{t} = 2. \qquad (3)$$

For the present purpose T can be divided into three parts:—Tension doing useful work, tension from centrifugal force, tension to balance the strain for adhesion. The tension t can be divided into two parts:—Tension for adhesion, tension from centrifugal force. It is evident, however, that the tension required to do a given work should not be materially exceeded during the life of the rope.

There are two methods of putting ropes on the pulleys; one in which the ropes are single and spliced on, being made very taut at first, and less so as the rope lengthens, stretching until it slips, when it is respliced. The other method is to wind a single rope over the pulley as many turns as needed to obtain the necessary horse-power and put a tension pulley to give the necessary adhesion and also to take up the wear. The tension t required to transmit the normal horse-power for the ordinary speeds and sizes of rope is given in Fig. 2, computed by formula (6). The total tension T on the driving side of the rope is assumed to be the same at all speeds. The centrifugal force, as well as an amount equal to the tension for adhesion on the slack side of the rope, must be taken from the total tension T to ascertain the amount of force available for the transmission of power.

I have assumed that the tension on the slack side necessary for giving adhesion is equal to one-half the force doing useful work on the driving side of the rope; hence the force for useful work is—

$$R = \frac{2(T - F)}{3}, \qquad (4)$$

and the tension on the slack side to give the required adhesion is—

$$\frac{(T - F)}{3}. \qquad (5)$$

Hence,

$$t = \frac{(T - F)}{3} + F. \qquad (6)$$

The sum of the tensions T and t is not the same at different speeds, as the equation (6) indicates.

As F varies as the square of the velocity, there is, with an increasing speed of the rope, a decreasing useful force, and an increasing total tension t on the slack side. With these assumptions of allowable stresses, the horse-power will be—

$$H = \frac{2\,v\,(T - F)}{3 \times 550}. \qquad (7)$$

Transmission ropes are usually from 1in. to 1¼in. in diameter. A computation of the horse-power for four sizes at various speeds and under ordinary conditions, based on a maximum load equivalent to 200lb. for a rope 1in. in diameter, is given in Fig. 1. The horse-power of other sizes is readily obtained from these. The maximum power is transmitted, under the assumed conditions, at a speed of about 80ft. per second.

The first cost of the rope will be smallest when the power transmitted by it is greatest, and, under the assumed conditions, will be a minimum for a given power when the velocity of the rope is about 80ft. per second. The ratio of the first cost of the rope running at any other speed will be—

$$\text{Ratio of first cost} = \frac{H \text{ at 80ft. per second}}{H \text{ at required speed}}. \qquad (8)$$

The wear of the rope is both internal and external; the internal is caused by the movement of the fibres on each other, under pressure in bending over the sheaves, and the external is caused by the slipping and the wedging in the grooves of the pulley. Both of these causes of wear are, within the limits of ordinary practice, assumed to be directly proportional to the speed. Hence, if we assume the coefficient of the wear to be k, the wear will be kv, in which the wear increases directly as the velocity, but the horse-power that can be transmitted, as equation (7) shows, will not vary at the same rate.

If we divide the value for wear at a given speed by the horse-power that the same rope will transmit at other speeds, we get the relative wear of the rope in transmitting 1 horse-power. The higher the speed, up to about 80ft. per second, the more power will be transmitted, but it is accompanied by a more than equivalent wear.

The rope is supposed to have the strain T constant at all speeds on the driving side, and in direct proportion to the area of the cross-section; hence the catenary of the driving side is not affected by the speed or by the diameter of the rope.

The deflection of the rope between the pulleys on the slack side varies with each change of the load or change of the speed, as the tension equation (8) indicates. The deflection or sag of the rope may be computed for the assumed value of T and t by the parabolic formula—

$$S = \frac{P\,L^2}{8\,D} + P\,D, \qquad (9)$$

S being the assumed strain T on the driving side, and t, calculated by equation (6), on the slack side.

It is to be regretted that accurate data are not available to determine the constants needed in the equations for wear and for friction on the pulley. No estimate has been made, as this paper is intended to state the general limitations of this mode of transmitting energy rather than to give details of its application.

THE OLSEN TESTING MACHINE.

(From our New York Correspondent.)

THE Olsen testing machine is one of the well-known type in which the specimen to be tested is placed between drawheads, one of which is moved by screws actuated by gearing from a shaft driven from any source of power, while the other rests on the levers of a weigh-scale. In the illustrations the drawheads are represented at 1 and 5. The drawhead 1 is carried on columns 2, which are secured to the platform 3. This platform 3 is carried on pivots shown at 4 on the double lever 117, the fulcrum of which is shown at 46. At the right hand end of lever 117, as shown in Fig. 1, this lever is suspended from a second lever, whose fulcrum is seen just to the right of 38 in the same figure, the other end of the lever being carried at the bottom of the link 119, the top end of which is attached to the short arm of the scale beam 118. The other drawhead 5 has attached to it in each corner inside the columns 2 large square-threaded screws, which are not allowed to turn, but inside the base are fitted with nuts driven from the power shaft through gearing shown at the bottom of the machine. 26 and 27 are the driving pulleys, one fitted with a straight and the other with a crossed belt. Both are loose on the shaft, but either may be connected by shifting the handle 33, which, through the fork 31, throws in either of the friction clutches 28 or 29. A change of speed when running in either direction can be obtained by moving the lever 25, which, operating a sleeve 19, throws either of two gear wheels into action, thus changing the speed. The nuts inside the base of the machine are driven from the shaft of the spur wheel 21. There is another very slow speed on the machine by which the time of testing an ordinary wrought-iron or steel specimen can be extended to probably an hour. On the end of the driving shaft, on which 26 and 27 turn freely, is a narrow grooved wheel shown at 34. To the wheel 27 is attached a pulley 43, turning with it, and, of course, also loose on the shaft. A belt connects this pulley with a pulley 41 on one end of a tilting shaft 40. The other end of this tilting shaft carries a small wheel, which, when in contact, drives 34, and thus the gears to 21. By means of the hand-wheel shown at 39 and the chain 37, the tilting shaft is moved so that the wheels 35 and 34 are in contact. Slacking off the wheel 38 allows the tension on the belt 42 to draw the wheels apart, and thus stop the machine.

The automatic method of moving the weight is ingenious. On the scale beam, and extending its whole length, is a square-threaded screw, shown at 105. This screw carries a friction wheel, into which a second can be made to gear. This second friction wheel is driven from a cord which leaves the scale beam vertically exactly in the line of its knife edges, and the cord receives its motion from the driving pulley 27 through the driving cord, shown in Fig. 3, between the number 41 and the belt on pulley 43. An electromagnet serves to throw the friction pulleys on the scale beam in and out of gear. The circuit through the electromagnet is closed as the beam rises by the touching of the contact points on the end of the scale beam and on the beam guard. Should the beam rise excessively the circuit is closed through the electric bell, shown in Fig. 3, warning the attendant. Any desired speed can be given to the screw 105, as the cord is driven through a set of three friction wheels, the position of the centre of the middle wheel being adjustable at will with regard to the centres of the others, thus regulating the speed transmitted.

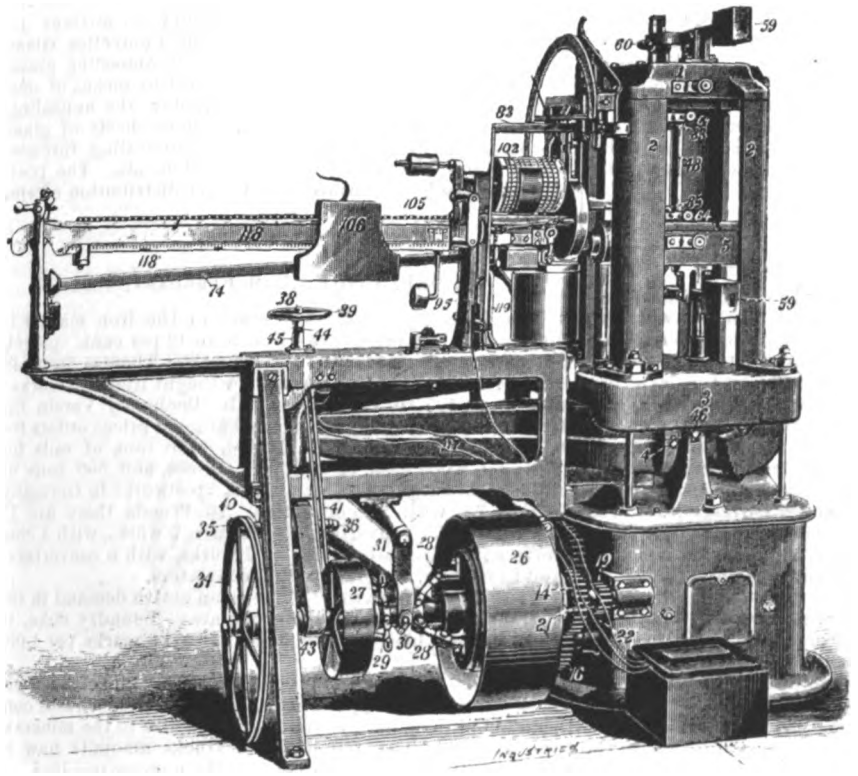
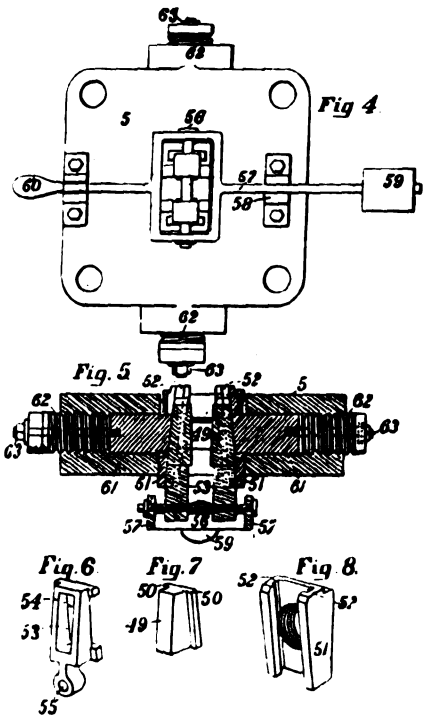
THE OLSEN TESTING MACHINE.





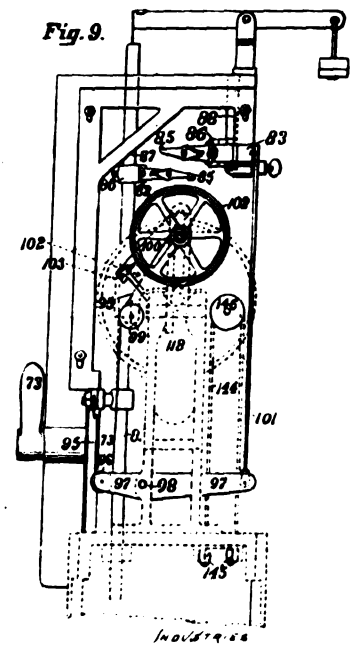


FIG. 3.

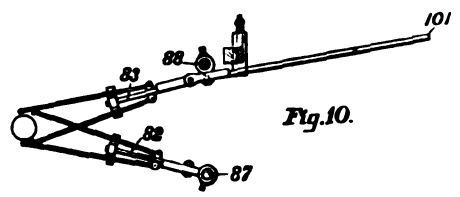

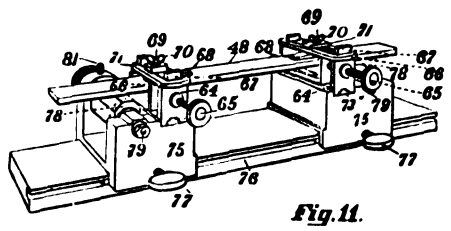

The method of rapidly taking hold of the specimens is shown in the large figures and in detail in Figs. 4, 5, 6, 7, and 8. In the illustrations a piece is shown in the machine to be tested in tension. After the piece is prepared, as described later, it is put between the jaws, the collar 65 resting on the lower jaws. The handles marked 60 are then drawn towards each other with considerable force, and the piece is clamped. The jaws are shown in Fig. 7, 49 being the gripping face. These jaws are carried in the slotted slides shown in Fig. 6, the gripping face extending through the opening shown, the projections on the back of the slide and the projecting flanges 50 of the jaws fitting into the grooves 52 of the block slide 51 of Fig. 8. These block slides are carried on the ends of the screws 62 of Fig. 5, by the aid of which the distance between the faces of the grips, or the size of the specimen taken, can be adjusted for. The slides carrying the jaws have an eye 55 (Fig. 6), by which they are secured by the bolt 56 to the handles 60 already spoken of, which are used to bring the grips against the specimen.

In addition to the automatic adjustment of the weight on the scale beam, the machine also automatically draws the diagram showing the change in length of the specimen and the load. The diagram is drawn on paper placed on the drum 102; the pencil 103, which is actuated from the screw 105, or rather from the same mechanism that operates 105, moves to the left, as shown in Figs. 1 and 2, proportionally to the load. The extension of the specimen causes the cylinder 102 carrying the paper to turn.

The method of preparing the specimen for use in the machine is shown in Fig. 11. A base block 76 carries two pieces 75, which can be set at any desired distance apart. Each of these pieces carries a spindle 79, having flat faces on it, as shown at 78, so laid out that if the specimen is laid on the face marked with the thickness of that specimen the centre line of the specimen is exactly parallel to the base. On a second projection 73 is then laid the clamps, the centres of the screws 65 of which are exactly on the centre lines of the specimen, and by tightening these screws the clamps are firmly attached to the specimen, and always at exactly the correct distance apart, so that with this apparatus specimens of various thicknesses and breadths can be almost instantly prepared for the machine. The specimen is then put in the machine, and the hand levers 60 are used to tighten the jaws and hold it in place. The fingers 82 and 83 are then shifted vertically on the rods 87 and 88 carrying them, until one bears on the top of the bottom collar or clamp, and the other bears against the bottom of the top clamp, as shown in Fig. 1. A view of these fingers is given in Fig. 10, where it will be seen that each finger has a bearing on both sides of the specimen, and is so arranged that only the mean of the movement on the two sides of the specimen is transmitted. As shown in Fig. 9, the bottom finger 85 is attached by the clamp 86 to a vertical sliding bar 87. This bar carries a projection, to which is attached a cord 95, which first passes over a pulley 96, and thence upwards to a pulley 99 in the line of knife edges of the scale beam, and to a pulley on the recording drum, shown at 100. A light spring holds the drum against the cord. The other finger 85 is connected to the upright rod 88, and also to a link 101, which takes hold of a lever 97, which is pivoted at 98, and carries on the other end the pulley 96, over which the cord from the other finger 85 leads. If we suppose now that the finger attached to 87 moves downward, the cord 95 would pass around the sheave 96, and the wheel 100 would wind up the same amount of line. If, at the same time the end of the upper finger moved downward the same distance, the lever 83–100, turning about the centre A, shown in Fig. 10, would cause 101 of Fig. 9 to move upwards the same distance, the right hand end of the lever 97 to move upward the same distance, and the left hand end or the wheel 96 to move downward one-half the distance, and the same amount of cord taken off the drum as the movement of the other drum allowed to go on, the result being that no extension would be recorded as should be the case.

By means of a multiplying device the elongation is indicated on a large scale by a pointer moving over a sector of large radius, as shown at the top of Fig. 2. As the divisions on the scale beam 105 are small for large increases of load, the left hand end of the actuating screw, as shown in Fig. 2, carries a dial on which the smaller divisions are placed, only one of which can be seen at a time through a covering plate, shown down and to the left of 103. The machine is so arranged that transverse, compression, or torsional tests can be made and diagrams drawn by the machine.

ELECTRIC MOTORS FOR GUNNERY PURPOSES.

THE Société des Forges et Chantiers de la Méditerranée have been experimenting with the application of electric motors to heavy guns for elevating and depressing and for moving them into direction. A separate motor is used for the two purposes, and it has been found that a considerable saving of time is effected in getting the gun into position as compared with other systems. The guns for three men of war, which are now being completed in France for the Government of Chili, are to be fitted with such motors, which are lighter and cheaper than the hydraulic apparatus hitherto used. It is intended to run the motors from the electric light circuit.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 24th February, 1891.

Iron.—The iron market continues inactive, but the prospects of increased business will, no doubt, be realised in course of time. The Western Railway Company (Chemin de Fer de l'Ouest) are on the point of ordering several hundred coal waggons, the recent frost having proved the deficiency. This company have also given a contract for 3,000 tons of rails to the Jœuf Steel Works at 94s. per ton. The State Railways (Chemins de Fer de l'Etat) are going to order 50,000 tons of various permanent way material. The nominal quotations fixed by the Paris Syndicate remain unchanged—viz., 128s. 6d. and 136s. 6d. respectively for bars and joists. The commercial prices are 120s. 6d. for bars, and 132s. 6d. for joists per ton. Castings stand firm at 112s. 6d., and old rails at 67s. 6d. In the Haute-Marne the iron works are fairly busy, but there is no improvement in prices. Reports from the Meurthe-et-Moselle and the Nord show a continued want of animation in affairs. The Northern Railway Company have given the following orders for execution in the latter district:—Fifty 4·20 metres turntables at 158s. 3d. per ton, and 514 sets of signalling apparatus, of which the prices vary between 337s. 6d. and 482s. per ton. The situation seems to be improving in the Ardennes, where the men who were out on strike are resuming work; in this district the demand for iron work for railway carriages is very brisk, also the nailmakers are commencing to have plenty of work.

A Large Hydraulic Press.—The Forges et Aciéries de la Marine have just put up a hydraulic press which will exert a pressure of 4,000 tons. It was constructed by Croyet & Co., of Chambon, and the cost of the installation is said to amount to nearly £60,000.

New Bridges at Lyons.—The greater part of the bridges across the River Rhône in and about Lyons being old and insufficient for the present requirements of traffic, the municipal authorities decided some time ago to replace three of them with new and modern bridges of steel. Two of these, the Pont du Midi and the Pont Moraud, are now completed, while the other, the Pont Lafayette, is expected to be ready very shortly. The contracts for the two first bridges have been carried out by the Compagnie Fives-Lille and Schneider & Co., Le Creusot. For each of the bridges 3,000 tons of iron and steel were required.

Electricity.—The use of the telephone for the hearing of theatrical performances is meeting with continued success here. There are now over thirty different clubs, hotels, and cafés connected up with the Théâtrephone Company's lines, and others are daily joining.—Mr. Julien, who has successfully formed several companies in the United States and the Brazils for working his patents relating to electric traction and accumulators, is on the point of forming a company here for the same purpose. This may give an impulse to the use of electricity as a tractive power in Paris, where, up to the present, this method has been but little employed.

French Shipbuilding.—The Government has put in hand, at Cherbourg, the cruiser "Bugeaud," making, with the "Fleurus" and the "Chasseloup-Laubat," a total of three vessels commenced since the 1st of January in the above yards.

BERLIN, 23rd February, 1891.

Electric and Gas Lighting in Berlin.—The following statistics have been collected by the Berlin Electricity Works with reference to the progress of electric lighting in Berlin, including the lights served by its own system and by other installations, the numbers being taken on the 1st April of each year:—

	1889.	1890.	Increase in 1889–1890.
Arc lamps	3,778	4,944	1,166
Incandescent lamps	62,876	80,788	17,912

Of this number the Berlin Electricity Works supplied the following proportion by means of their central stations:—

Arc lamps for private and public lighting	970	1,832	862
Incandescent lamps	31,417	43,215	11,798

The remaining 3,112 arc lamps and 37,573 incandescent lamps were supplied from 262 installations, for which the motive power is given by steam engines and gas engines as follow:—

Steam engines	158	171	13
Gas engines	79	91	12

The 5 arc lamps and 6,163 incandescent lamps in the two Royal theatres are included in the number given as supplied by the Electricity Company. On the supposition that one arc lamp is equal to six incandescent lamps, and each incandescent lamp is equal to one gas lamp, the total number of electric lamps on the 1st of April, 1890, gave light equal to 110,452 gas lamps, of which 54,207 was the amount supplied by the Berlin Electrical Works, and 56,245 by private installations. The total number of electrical lamps at the end of the working year, as reckoned on the above supposition, showed an increase of 29 per cent. over the previous year, whilst the electrical works showed an increase of 46 per cent., and private installations of 16 per cent. The district hitherto lighted by the electrical works is one of the most favourable in Berlin, since it includes many important business establishments, the Royal theatres and bank premises, as well as large private houses, to the owners of which cost of lighting is of small importance. Notwithstanding the extension of electric lighting in this district, there has been an increased use of gas during the past year, and if the same proportion should be maintained in the two other districts, where central stations are to be opened, an enlargement of the gas works plant will be necessary.

VIENNA, 23rd February, 1891.

The Iron Market.—Prices showed a continual decrease up to the first part of last week. The Bohemian Syndicate of Iron Works were obliged to diminish the price of bar iron by 5fl. per ton, in order to compete with German works, and the price of bar iron is now 112·50fl. per ton. During the past few days negotiations between the Austrian Syndicate and the German Union of Rolling Mills have resulted in the agreement being prolonged to the end of 1893. It is therefore expected that the iron market will shortly resume its former condition. An important order for 14 locomotives, 13 tenders, 53 passenger carriages, and 128 goods waggons has been placed by the Austrian State Railways. The Austrian Waggon Loan Company has resolved to increase its rolling stock by 300 carriages, and its capital is to be increased by 500,000fl.

The Coal Market.—The coal market still continues very active. At a recent meeting of the Salgo Tarjan Coal Mines and the North Bohemian Coal Company, which are two of the most important coal mines, a report was presented to the shareholders. During the past year the Salgo Tarjan Mines made an output of 660,650 tons of manufacturing coals, which amounts to 58,327 tons more than in the previous year. The profits were more than 700,000fl., and a dividend of 20fl. will be paid, as compared with 16fl. in the previous year. The North Bohemian Company made a profit of 336,000fl., and pays a dividend of 16fl., or 8 per cent. on its capital. Its total production amounted to 834,355 tons.

Electrical Engineering.—During the past week the "Neubad" (Vienna) central station, belonging to the firm of Messrs. Siemens & Halske, with its cable system 16 kilometres in length, was taken over by the General Austrian Electricity Company. All the duties and privileges with regard to this station were transferred by the municipality to the new company.—The Budapest central station of this company, by means of which the street railway is worked, will be considerably enlarged, and will supply power for the industrial undertakings along its route.—Weisskirchen, a town in Moravia, has determined to erect a central station for the electrical lighting of the streets, squares, and public buildings. Engine power of about 300 horse-power will be used in the working of it.—Chotzen also, a town in Bohemia, intends to erect a central station for electric lighting.—The Hungarian State Railways are introducing electric lighting on the express trains. Up to the present time eight carriages have been provided with Tudor accumulators, and if the trial should prove successful electric lighting will be generally introduced.—The Vienna Stock Exchange and the larger railway stations have been recently lighted electrically.

Exhibition at Budapest.—A special Exhibition, in connection with the cement, earthenware, asphalt, stone, and marble industries, will be held at Budapest from May 15th next to June 30th. No charge will be made for space in this Exhibition, and a reduction in freight will be allowed by the German and Austro-Hungarian railways on all goods intended for this Exhibition.

BRUSSELS, February 24th, 1891.

The Iron Trade.—In consequence of the receipt of orders, and of the present price of raw material, makers have decided to keep up the prices. Erecting shops continue actively at work. The Liège rolling mills are receiving numerous orders, and a rise in the price of iron will necessarily follow. At Charleroi trade is not so favourable. There are better accounts, however, of trade in foreign countries, and it is hoped that the Chicago Exhibition will give a considerable impetus to business. The Bruges workshops have just obtained an order for a gasometer at Ostend. It seems probable that one of the oldest mines in Belgium will now be worked by a limited company.

The Coal Market.—The coal market is firmer than it was a week ago, and the lowering of prices seems to have stopped. Prices at Charleroi fluctuate largely, but large sales of second qualities at 11fr. to 12fr., and of small coal at 9fr. to 10fr. have taken place. At the Liège coal mines the production is very brisk. A year and a half ago the stock at the Belgian coal pits was at a very low ebb, but an improvement took place during the first half of the past year through an increase in the production. At Charleroi especially stocks have increased rapidly, and this circumstance shows itself in various ways. The coke market remains very favourable, and any immediate alteration is unlikely.

The Glass Trade.—The production is still in excess of the demand, which is, however, a little brisker. Prices continue to become lower, and some manufacturers offer goods at unremunerative prices. This system of cutting prices is injurious, since it causes buyers to wait for a still further reduction, and thus prevents the placing of orders. If sellers were to adopt a sounder policy the market would soon improve, and buyers would be anxious to place their orders for the spring. The Courcelles Glass Company are using a new method of annealing glass. The former method of heating one sheet by means of one furnace has been modified so as to allow the annealing of two sheets at the same time. These sheets of glass are arranged in pairs in an enlarged annealing furnace, which is provided with suitably placed hoods. The position of these hoods ensures the proper distribution of the heat.

DÜSSELDORF, 24th February, 1891.

The Iron Market.—The state of the iron market is unaltered. The prices are—For 10 to 12 per cent. spiegel, 59 marks; pig iron, No. 1, 54 marks; Thomas iron, 49 marks; hematite iron, 78 marks; wrought iron, 135 marks; fine sheet, 135 to 145 marks. The Bochumer Verein für Gussstahlfabrication has received at good prices orders for 8,000 tons of steel rails for Mexico, 6,000 tons of rails for Portugal, 2,000 tons of rails for Greece, and 500 tons of rails for Norway. The number of steelworks in Germany is now 22, with 83 converters. In Prussia there are 17 works, with 71 converters; in Bavaria, 2 works, with 4 converters; in Elsass-Lothringen, 2 works, with 6 converters; and in Saxony, 1 works, with 2 converters.

The Coal Market.—There is an active demand in the coal market. The prices of coke are:—Foundry coke, 16 to 18 marks; blast furnace coke, 13 to 14 marks, per 1,000 kilogrammes.

Transportation Difficulties.—The want of waggons, both here and in Upper Silesia, continues, and causes considerable injury both to the works and also to the miners in the district. The deficiency of trucks amounts now to 1,025, or almost to 23 per cent. of the number required.

The German Coal Export to Italy.—The export amounted to 119,760 tons in 1889, and to 71,260 tons in 1890. Of these amounts the Saar district accounted for the largest share, while the Westphalian district showed only 63,120 tons in 1889 and 48,230 tons in 1890. It is probable that the returns for the current year will be still worse if cheaper freights are not obtainable.

Siegen Sheets.—The production of thin sheets, which has for a long time past been successfully carried on in the Siegerland and some districts of the Lower Rhine, is estimated to be about 2,800 tons weekly. Until October of the past year all works concerned in the manufacture of this article were included in a syndicate which worked in a fairly satisfactory manner. At that date the syndicate collapsed, and prices suddenly dropped down from over 200 marks to 130 marks. As this selling price does not cover the costs of manufacture, endeavours to renew the syndicate are being made.

AMSTERDAM, 23rd February, 1891.

Railways.—The Minister of the Means of Communication has had to defend his administration in the two Chambers of the States-General against the attacks of several members, based upon the general breakdown of the railway service during the late severe frost. The Minister could not, of course, deny that such a paralysis of the whole train service had indeed occurred, but he denied that there was much connection between the lamentable stoppage of nearly all traffic on the railways and the recent reorganisation of the railway system, in consequence of the purchase of the Dutch-Rhenish Railway by the State. The Government had, on the contrary, a conviction that the severe winter was alone the cause of the general breakdown, and that the companies could not fairly be held responsible. The fact was that the vast majority of goods in the Netherlands were carried by water, and a small proportion only by rail. Goods, usually transported by steamers or barges, might upon occasions be delayed by frost for a few days without causing serious inconvenience. But the case became different when a persistent frost, like the one commencing last November, closed all navigation for many weeks. The fact that Flushing and Rotterdam were able to keep open their harbours the whole time—although very satisfactory in itself—only tended to increase the glut, as foreign transports competed with home transports. However, the difficulties were now a thing of the past, and the Minister stated he hoped a similar state of affairs would not occur again in Holland for the next twenty-five years at least. In connection with this subject, it has to be noted that the Government refused to support a project to connect Amsterdam and Ymuiden, at the mouth of the North Sea Canal, by rail—a scheme lately revived in consequence of the closure of navigation in the canal during the great frost. The above-named Minister declared in the First Chamber that he would not refuse to entertain a private concession for such a railway, but a State guarantee or subvention was out of the question.

The Industrial Art Museum.—The management of this institution at Haarlem has arranged for a series of special exhibitions by various large manufacturers of Holland. The whole will, therefore, form a kind of cycle of national industries in their latest developments.

Digitized by Google

STOCKHOLM, 21st February, 1891.

Labourers' Share in Profits.—The Ystad Sugar Refinery has paid all its men a share in last year's profits. Their share is a cash payment of 3,086kr., which is equal to 27kr. per man, there being 125 men, and a sum of 9,260kr., which goes to the men's pension fund. This fund now amounts to 20,137kr., and is intended to provide a pension for those who have been at least ten years at the works. The pension has been fixed at 200kr., to begin at the age of 60 years for the men and at the age of 55 years for the women.

The Swedish-Norwegian Railway Company.—The King of Sweden in Council has now sanctioned the purchase by the Swedish State of the Swedish-Norwegian Railway Company's Lulea-Ofoten railway line for a sum of 6,500,000kr., for which the Swedish Parliament had already voted the purchase money. The debenture holders will now probably make overtures to the Norwegian Government with the view of their taking over the railway now in progress from Ofoten in the direction of the Swedish frontier. This section of the line is of no value to the company under the present circumstances, and the works already completed are bound to quickly deteriorate if left in their present state.

New Steamer.—The Göta Steamer Company, Gothenburg, has contracted with the Bergsund Engineering Company, Stockholm, for the building of a new steamer. The steamer is to be 900 tons, and is to be fitted with triple-expansion engines. The material is to be the best Swedish Bessemer steel, and the date of delivery is the 1st of August.

New Telephone Lines.—The use of the telephone is being extended to all parts of Sweden, and it is now proposed to connect several places in the Bohnslön Stargard by submarine telephone cables. This installation will probably be undertaken by the State Telephone Administration.

CHRISTIANIA, 21st February, 1891.

Proposed Extension of Bodö Harbour.—The extension of Bodö Harbour is now likely to be realised. The calculated cost is about 600,000kr., of which the greater portion will be absorbed by the building of a stone pier of 230 metres in length.

Export of Ice and Timber.—The shipments of ice and timber during the month of January have not exceeded half of those for the same month of last year. 3,618 tons of ice were shipped against 7,566 tons in January, 1890, and 39,058 cubic metres of timber against 65,462 cubic metres in January, 1890. The largest shipments of timber are from Frederikstad and Drontheim; of ice, from Brevik, Longesund, and Christiania.

Electric Light at Hammerfest.—Hammerfest, the most northerly town in Europe, is the first town in Norway to be lighted completely by electricity. The installation is on the Thomson-Houston principle, and the motive power is supplied by a waterfall at about a mile distance. The installation is satisfactory, and will be extended so as to light the harbour.

New Cargo Steamer.—The new steamer "Transport I.," which is being built for a Christiania syndicate, is of a somewhat unusual type. Its dimensions are:—Length, 120ft.; breadth, 20ft.; and depth, 9½ft. It is specially constructed with a view of being able to carry large and heavy articles, and the engine is placed right aft.

COPENHAGEN, 21st February, 1891.

Engineering.—The large establishment of Burmeister & Wain's Shipbuilding and Engineering Company has been kept fully employed during 1890. The dividend for last year will be 6½ per cent. The manufacture of cream separators will soon be further extended so as to comprise centrifugal appliances for the beer and wine industries.

The Beer Tax.—The vexed question of a beer tax, which is at present before the Danish Parliament, is likely to be satisfactorily settled. It is intended to tax only such classes of beer as contain a certain percentage of alcohol, and the technical difficulties seem now to have been partially overcome. That the new tax is strongly objected to by the brewers is only natural.

Iceland.—The works on the large bridge over Alvesoa are steadily progressing, and the materials for the bridge have now been brought to their destination. This was, however, no easy matter, as the larger pieces could only be conveyed on sledges. During the summer a number of engineers will arrive to fix it.

MADRID, 23rd February, 1891.

Exhibition of Wines at Badalona.—An Exhibition of wines and brandies and of implements and machinery connected with the cultivation of the vine is to take place at Badalona, in Catalonia, in March next. Considerable interest is shown in the success of the Exhibition, and liberal prizes are offered, in addition to those for produce and machinery, to those workmen who show most skill in the difficult manual operations connected with the culture of the vine.

Grain Market at Madrid.—The want of a grain market at Madrid has been seriously felt for many years, and, after much discussion, the work has at last been commenced. The market is situated midway between the two largest railway stations.

Ministerial Visit to the Province of Huelva.—The Minister of Public Works, who has under his charge the mining industries of the country, accompanied by the Minister of the Colonies, has just visited Huelva in order to make inquiries with regard to the fumes question, which is to be brought before the Cortes for settlement. The Minister favours the policy of the present Government in not wishing to interfere with the roasting of pyrites in the open air. At the same time he considers that the agricultural classes should have easy means of obtaining compensation for damage done to their crops. One of the alcades of the villages, which have been most injured by the fumes, had stated that some of the mines were quite satisfied with the results of having discontinued the roasting, but the Minister considers this argument to be of little weight. It is probable that in any event the amount of roasting will be diminished.

Railway from Linares to Almeria.—The new survey which has been made by the projectors of this railway has been approved of, and the construction of the line will now be rapidly carried out. The line could be completed in two years if the money were readily forthcoming, since short tunnels are to be substituted for the long ones previously projected, and none of the work requires a lengthened time for its construction. Under all the circumstances it seems probable that the work will be completed in four years.

Sugar Industry in Spain and in Cuba.—The first manufacturers of beet sugar in Spain have met with so much success that it seems probable that eventually there will be enough made in the peninsula for the home consumption without importing any sugar cane from Cuba. This question has caused some jealousy to be felt by the planters in Cuba, who see that the success of the Spanish manufacturers is due to the existence of import duties. It has been overlooked that the continuance of the present crops can only be maintained by means of a large expenditure on manures. Many new factories are, however, being started, amongst which one is to be established at Aranjuez, where there is a large extent of land under irrigation. The Cuban planters demand that some measures should be taken to give them equal advantages with the Spanish manufacturers. The sugar cane plantations in Spain are losing credit by reason of the damage done by such cold winters as the present one.

ROME, 23rd February, 1891.

Florio and Rubattino United Steamship Companies.—The report presented to the shareholders of the Navigazione Generale Italiana (Florio and Rubattino United Steamship Companies) shows that in the year 1889-90 the net profits amounted to £116,910. It was decided to pay a dividend of 5 per cent., carrying forward £6,910. The gross income of the company amounted to £1,864,270, whilst the gross expenditure amounted to £1,747,360. During the past year the company has been compelled to reduce the sailings for South American ports, owing to the diminution of the Italian trade with those countries, and also had to give up the line to the Pacific as it was not remunerative. This loss has, however, been partly compensated by the Government charters for the Red Sea service, and by the starting of new lines to foreign ports. The company now owns 106 steamers, capable of carrying 102,989 tons, and their value is estimated at £2,466,800. The company has invested £72,000 in the building of dry docks at Genoa for the cleaning and repair of large steamers. The subventions paid to the company by the Governments during the past year amount to £376,274. The company also receives £2,080 from the British Government for the mail service. The passenger receipts for the various lines amounted to £562,492, and the freights to £798,114.

Commercial Museum at Rome.—Under the patronage of the Italian Government, a commercial museum has recently been established in Rome. The museum will be a permanent exhibition of the products of Italy and foreign countries. A charge is made for space, and the committee undertake the representation of those firms desiring to exhibit.

Roman Ship Canal.—As briefly mentioned a week or two ago, a project has been presented to the Minister of Public Works in Italy for the construction of a ship canal from Rome to the Tyrrhenian Sea. This canal will have a length of nearly fifteen miles, and its width will be about 270ft.

NEW YORK, 14th February, 1891.

Grand Central Station at Chicago.—The new Grand Central Station at Chicago, Ill., has a frontage of 680ft. on Fifth Avenue and 226ft. on Harrison Street. The train shed has a single arch span of 59½ft. radius, spreading out at the sides to make a total width of 146ft. over the platforms, which are 19ft. wide and 10in. high above the rail. The spaces between them are 23ft. wide, accommodating three sets of tracks. According to the *Engineering News*, it is lighted by sixty groups of incandescent lamps, ninety lamps of 32 c.p. at each end, and seven powerful arc lights high up in the roof. The main waiting-room is 71ft. by 267ft. and 25ft. high; ladies' waiting-room, 32ft. by 40ft.; dining-room, 53ft. by 73ft. The tower is of Connecticut brownstone; it is 27ft. square and 236ft. high. The clock face is 13½ft. diameter. There are three engines, aggregating 550 h.p., driving the electric light plant, which has a total capacity of 127,000 c.p. Compressed air is used to operate the switches, block signals, drawbridge, and all crossing gates within four miles of the station. It is in its general effect one of the handsomest and most luxurious stations in America, although in size it is not specially remarkable.

Chicago Street Railway.—During the past year the Chicago Street Railway Company carried a total of 68,734,969 passengers, receiving therefrom $3,436,748. The expenses of operation were $2,297,651, and the net was $1,139,097, or 18 per cent. on the capital. This company operates 152 miles of track, of which 34 miles are cable and 118 are horse lines. During the year 685 horses were bought at an average of $125 per head, and 268 were sold at an average price of $130. The daily cost for each horse, including food, attendance, depreciation, harness, was 47⅞c. The total number of cable-car miles was 12,740,480, and the working expenses per cable mile were 9·650c. The total number of horse-car miles was 4,859,200, and the working expenses per horse-car mile were 21·985c. Two hundred and eighty-two cases of damages by accidents were settled at a total expenditure of $30,809.

Immigration.—Immigration for 1890 compares with 1889 as follows:—

	1890.	1889.
English, Welsh, and Scotch ...	67,255	77,439
Irish ...	53,312	60,375
German ...	96,482	95,935
Swedish, Danish, Swiss, &c. ...	59,941	58,349
Italian ...	62,492	29,606
Austro-Hungarian ...	63,095	42,170
Polish ...	19,737	4,866
Russian ...	40,883	33,474
Dutch, French, and other ...	27,829	24,498
Total ...	491,026	426,712

The increase is entirely from the less desirable races of immigrants, which now constitute over 40 per cent. of the total, a fact which ought to lead to some provisions for judicious restriction of the privilege of immigration to those fit to enjoy it.

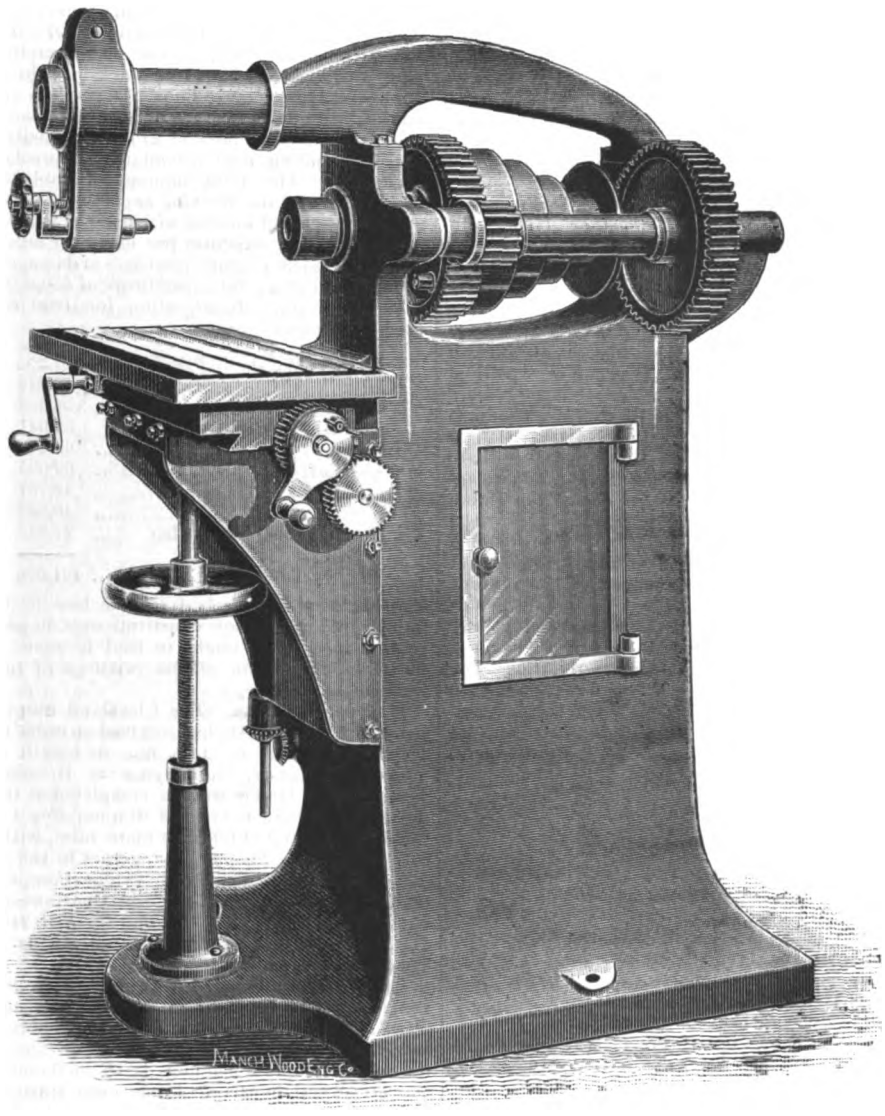
Marine Boilers.—The Cleveland Shipbuilding Company, of Cleveland, O., has received an order for two boilers 11ft. in diameter, by 10ft. 6in. in length, for the ocean steamship "Kinau," now lying at Honolulu, Sandwich Islands. The boilers will be completed at the boiler shop department of the Cleveland Shipbuilding Company, then taken apart, and shipped in plate form, with rivets, flues, &c., all complete for putting together in the steamer.

New Bridge.—The Smith Bridge Company, of Toledo, Ohio, has completed a bridge at Chattanooga, Tennessee, having three spans of 320ft. and three of 210ft., roadway 27ft. wide with two sidewalks 6ft. wide. Mr. Edwin Thacher was the chief engineer.

The Pennsylvania Steel Company.—The Pennsylvania Steel Company is making important additions to its plant located at Sparrow's Point, Baltimore, Md., and at Steelton, Pa. The frog, switch, and signal department, which now employs 300 men, is to be doubled. A bridge and structural department has been started, and placed under the management of Mr. Charles E. Billin, who was recently in charge of a similar plant at the Pencoyd Iron Works, Pa.

PHILADELPHIA, 13th February, 1891.

Sugar Refinery.—The sugar refinery at Curtis Bay, Baltimore, was formally opened yesterday. The machinery, which has been under test for the past six weeks, has been found to be in good order, and everything is working smoothly. For some time yet the refinery will be operated on a limited scale, but after April 1st, when the new Tariff Act relating to sugar comes into effect, making it free, the refinery will be worked to its fullest capacity, and will turn out from 1,200 to 1,500 barrels a day.



Railroad Consolidation.—Considerable interest has been manifested during the past ten days in a trip made through the South by a number of railroad men interested in Southern and Western railroads. It seems probable that all the principal roads south of the Pennsylvania and the Union Pacific Railroads will join in a friendly understanding as to rates and division of business. The plan provides for entrance into Philadelphia and New York over the Baltimore and Ohio, and a combination of roads north of the Ohio River, affording entrance into Chicago, Pittsburgh, and Western New York. The result promises to be the largest trunk line combination in the country, rivalling the New York Central and the Pennsylvania lines from New York to Chicago.

Coke Workers.—The threatened strike in the coke region has begun, and there are now about 16,000 men out on strike, the greater part of these going out on the 7th inst., the coke drawers, to the number of about 6,000 men, remaining at work until the 11th inst. It seems unlikely that the dispute will be settled, as the men ask for an increase of 12½ per cent., and the operators propose to reduce wages 10 per cent. There are about 16,000 ovens in the Connellsville regions distributed among about seventy plants. The past year has been an unusually good one, as shipments were the heaviest ever known, and work has been correspondingly steady at good prices. Efforts to prevent the strike have been made ever since the beginning of the year. The larger consumers have stored enough coke to last them for sixty days, but, as the strike is likely to last several weeks, many of the smaller iron-works will have to close.

IMPROVED MILLING MACHINE.

CONSTRUCTED BY MESSRS. CUNLIFFE & CROOM, ENGINEERS, MANCHESTER.

GENERAL VIEW.

NEW BRITISH WARSHIPS.

ANOTHER of the second-class cruisers, the construction of which was authorised by the Naval Defence Act of October, 1889, was launched on the 10th inst. from the No. 5 slipway at Chatham Dockyard. H.M.S. "Apollo," the vessel in question, is built of steel throughout, and measures 300ft. in length, 43ft. in extreme breadth, and 25ft. in depth, with a displacement of 3,400 tons on a mean draught of water of 16·5ft. The vessel is of the protective deck type, and is provided with a double bottom extending over the engine and boiler spaces. Subdivision of the hull is a primary feature, there being no less than eighty watertight compartments, including those of the double bottom. The machinery consists of two sets of vertical triple-expansion engines, which are expected to develop 9,000 horse-power under forced draught, giving a speed of 20 knots. The coal supply at the load draught will be 400 tons, which will enable the vessel to cover a distance of 8,000 knots, without re-coaling, at a reduced speed of 10 knots. The "Apollo" will mount two 6in. quick-firing weapons, which are capable of piercing a 10in. armour plate at 500 yards, one being mounted on the forecastle and the other on the poop. In addition, there will be six 4·7in. 36-pounder quick-firing guns, eight 6-pounder Hotchkiss guns, one 3-pounder Hotchkiss, and four 5-barrelled Nordenfeldt machine guns. There are also four torpedo tubes, one at the bow, one at the stern, and two others on the broadside, capable of being trained through a very large arc of fire. In action the ship will be manœuvred from a conning tower, built up of 3in. rolled steel plates, and within which are placed the steering wheel and engine-room telegraphs. The vessel is to be rigged with two pole masts, carrying light fore and aft steadying sails. When complete, the "Apollo" will have a complement of 252 officers and men.

The leviathan first-class battle-ship "Royal Sovereign," building in the Royal Dockyard at Portsmouth, was launched yesterday, the launching ceremony being performed by Her Majesty the Queen. Yesterday, also, and from the same establishment, the first-class cruiser "Duke of Connaught," *ex* "Centaur," was launched. The "Royal Sovereign" is the largest vessel hitherto constructed for the British Navy, and when complete she will exceed in displacement the "Nile" and "Trafalgar," which have previously figured as the largest British warships, by fully 1,650 tons. She is one of a class of which there are seven, designed by Mr. W. H. White, Director of Naval Construction, to carry four heavy guns, *en barbette*, high above water. The remaining six vessels are at present under construction at the following establishments:—The "Renown" and "Repulse," at Pembroke Dockyard; the "Resolute" and "Revenge," at Jarrow, by the Palmer Shipbuilding Company; the "Royal Oak," at Birkenhead, by Messrs. Laird & Co.; and the "Ramillies," at Clydebank, by Messrs. J. & G. Thomson. The principal dimensions of the "Royal Sovereign" are as follow:—Length, 380ft.; breadth, 75ft.; mean draught of water, 27·5ft.; and displacement, 14,150 tons. In length she equals the "Warrior," "Black Prince," and "Achilles," the representatives of early armour-clad construction, while her beam is the same as that of the "Inflexible," hitherto the broadest ship in the navy. A belt of armour 8·5ft in breadth, with a maximum thickness of 18in., extends for 250ft. amidships. This belt is terminated by transverse armoured bulkheads, above which is built a 3in. steel protective deck. Above the thick armour belt the broadside is protected to the height of the upper deck by 5in. steel plates for a length of 145ft., while oblique bulkheads of armour stretch across the protective deck to meet the redoubt armour at the base of the barbettes. The armour on the barbettes is 17in. thick, and, in view of the development of high explosives, special protection has been afforded to the passing of the ammunition from the magazines, both to the barbettes and the central battery, where the auxiliary armament is located. With regard to speed this monster vessel is destined to outstrip all competitors, and in virtue of her greater length she will be capable of steaming a knot per hour faster than the "Trafalgar." In speaking of the relation of speed to power, and comparing the forms of the "Royal Sovereign" and "Trafalgar," Mr. W. H. White, in a paper read before the Institution of Naval Architects in 1889, says:—"The new ships are to be 380ft. in length, as compared with 345ft. in the 'Trafalgar.' They will be 14,150 tons displacement, as against 12,000 for the 'Trafalgar' as designed, and 12,500 tons for that ship as completed. Our model experiments show that for speeds from 10 knots up to 16 knots, the resistances of the two forms are, for all practical purposes, equal; the greater length of the new ships compensating for their greater displacement. But at speeds higher than 16 knots the longer form begins to gain sensibly on the 'Trafalgar,' and at 17 knots the 'Trafalgar' form would require about 12 per cent. greater power than the new ships. At 17·5 knots the 'Trafalgar' form, if it could be driven, would require at least 30 per cent. greater power than the heavier but longer ships. Now this speed of 17·5 knots is what is estimated as the maximum (forced draught) performance, with 13,000 horse-power in the new ships, while with 9,000 horse-power (natural draught) we hope to reach about 16 knots." The coal capacity amounts to 900 tons, and will enable the vessel to steam 5,000 knots at a 10-knot speed, or from 1,500 to 2,000 knots at her maximum speed. The armament of the "Royal Sovereign" will be of the most powerful description, and will consist of four 67-ton breech-loading guns carried in barbettes, while ten 6in. quick-firing guns will be placed in the central battery. In addition the auxiliary armament will be augmented by sixteen 6-pounder and eight 3-pounder quick-firing guns. The hull is pierced for seven torpedo tubes, of which two are submerged. According to the official programme, the "Royal Sovereign" is to be completed in December, 1893.

The "Duke of Connaught" is one of the first-class cruisers of the protective deck type which are being built under the Naval Defence Act. Between the perpendiculars she measures 360ft., in extreme breadth 60·7ft., and when complete for sea will have a displacement of 7,700 tons on a mean draught of water of 24·7ft. A watertight protective deck, 3in. thick, extends throughout the length of the hull, completely shutting off the frames below from those above, which are connected to the deck by steel angles and brackets. In this deck, which covers the vital portions of the ship, such as engines, boilers, magazines, &c., as few openings as possible are made, but where such are unavoidable, armoured shutters are provided, and where the cylinders protrude an armoured breastwork surrounds them, having a maximum thickness of 5in. An oval conning tower, built of steel plates, affords protection from quick-firing guns to the various engine-room telegraphs, voice tubes, directors, and steam steering wheel. The main armament will consist of two 22-ton breech-loading guns, and the auxiliary armament of ten 6in. quick-firing guns and sixteen 6-pounder and 3-pounder quick-firing guns. In addition, two above-water torpedo tubes and two submerged tubes are provided for the discharge of Whitehead torpedoes. Two sets of vertical triple-expansion engines are to be fitted, capable of developing collectively 12,000 horse-power under forced draught, and 7,500 horse-power with natural draught, the resulting speeds being estimated at 19·5 knots and 17·5 knots respectively. The normal coal supply is 850 tons. The total cost of the hull, machinery, and equipment of the "Duke of Connaught" will be about £328,000.

The "Hawke," a sister vessel to the "Duke of Connaught," under construction at Chatham Dockyard, is all but complete, and will be launched as soon as her boilers are received from the contractors for her machinery.

IMPROVED MILLING MACHINE.

WE illustrate above a milling machine for general work, which has been designed by Messrs. Cunliffe & Croom, engineers, Broughton Iron Works, Manchester. In general construction it resembles those commonly made, but special attention has been paid to rigidity, in order to get absolutely true work. With this object the vertical slide carrying the table has been strengthened and specially constructed, so that the horizontal surfaces of the slide are exceptionally broad, thus giving a good bearing for the table and ensuring steady work. The traverse of the tables in each direction is arranged to be self-acting, and disengaging motions are fitted by which the traverse may be stopped at any part of the stroke. Wherever miscellaneous work is being done, and one man is attending to more than one machine, these machines are found to be of great service.

THE DUBLIN "LOOP LINE."

THE line of railway between Amiens Street Terminus of the Great Northern Railway Company and Westland Row Terminus on the Dublin, Wicklow, and Wexford Railway in Dublin, known as the "Loop Line," is approaching completion. This loop line is not only of great local interest, but is also of general importance to the commercial interests of the United Kingdom, as it forms a through connection between Kingstown and Queenstown, where the mails are taken on board for the United States. The length of the line from Westland Row to Amiens Street Station is a little over a mile. It runs through the principal portions of the city, and the cost of construction was very materially increased by the purchase of buildings. It consists of eighteen iron bridges, with intervening brick arches having spans varying from 27ft. to 30ft. each. The iron bridges include the Liffey Viaduct, which is the principal one.

The best view of this viaduct is from Carlisle Bridge, and the illustration given on page 204 is taken from this point. At the north end of the Amiens Street Terminus are being erected new platforms for the convenience of passengers arriving by the trains coming over the Loop Line. These platforms will be made of concrete and covered, and on the arrival platform from Kingstown a lift is being constructed, upon which the mail bags will be raised or lowered. At this point there will be erected a signal box in which 70 levers will be worked. From here "No. 1" and "No. 2" lines commence. No. 1 line is that connecting the Loop Line with the Great Northern system to Belfast. No. 2 connects the Loop Line with the Liffey Junction Railway at Newcomen Bridge. This latter line was constructed jointly by the Great Southern and Western and Midland Great Western Railway Companies, and both systems have goods depôts at the North Wall. The viaduct and bridges have been designed by Mr. John Chaloner Smith, M.Inst.C.E., and Mr. William Hemingway Mills, M.Inst.C.E., and to the courtesy of the latter gentleman we are indebted for much of the information we now give.

SHIPBUILDING NOTES.

ON the 14th inst. Messrs. Laird Brothers launched from their works at Birkenhead an iron twin-screw steamer, the "Sir Richard Grenville," built to the order of the Great Western Railway Company, and intended for service as a mail and passenger tender at Plymouth. She has been built to Lloyd's highest class, and is about 132ft. long by 30ft. beam, with a tonnage of 545 tons O.M., and will be fitted with two sets of triple-compound engines driving twin screws. She will have a speed of about 12 knots.

ON the 16th inst. the fine steel screw passenger steamer "Fuping," built at Blyth by the Blyth Shipbuilding Company, Limited, for Mr. James Whittall, of London, per Mr. John White, also of London, for China trading, had a very satisfactory trial trip. The "Fuping" is a duplicate of the "Ching Ping," recently built for Mr. John White. She is 223ft. in length, and is fitted with Smith & Son's steam winches, Donkin & Nichols' steam steering gear, and Napier's patent windlass and capstan. The engines are by Mr. Middleton Pratt, of Huddersfield, and are of the triple-expansion type, and worked very satisfactorily.

Notices of Meetings.

THIS WEEK.

INSTITUTION OF CIVIL ENGINEERS.—Friday, February 27th, at 7.30 p.m. Students' meeting. Paper to be read: "Disintegrators," by Mr. B. Chatterton.

PHYSICAL SOCIETY.—Friday, February 27th. Papers to be read: "Proof of the Generality of Certain Formulæ Published for a Special Case by Mr. J. H. Blakesley," by Professor W. E. Ayrton and Mr. J. F. Taylor; "Further Contributions to Dynamometry," by Mr. J. H. Blakesley; "Note on Electrostatic Wattmeters," by Mr. Swinburne; "Interference with Alternating Currents," by Professor Ayrton and Dr. Sumpner.

SOCIETY OF ARTS.—Friday, February 27th, at 4.30 p.m. Lecture on "The Science of Colour," by Captain Abney F.R.S.

ROYAL INSTITUTION.—Saturday, February 28th, at 3 p.m. Lecture III., on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

BALLOON SOCIETY.—Friday, February 27th, at 8 p.m. Paper to be read: "British Borneo (Past, Present, and Future)," by Mr. W. B. Pryer.

MANCHESTER ASSOCIATION OF ENGINEERS.—Saturday, February 28th, at 7 p.m. Paper to be read: "Dr. Joule: with Special Reference to His Discovery of the Mechanical Equivalent of Heat," by Mr. J. Angell, F.C.S.

NEXT WEEK.

SOCIETY OF ENGINEERS.—Monday, March 2nd, at 7.30 p.m. Paper to be read: "The Balancing of High-Speed Steam Engines," by Mr. A. Rigg.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, March 2nd, at 8 p.m. Papers to be read: "The Chemical Changes between Nitric Acid and Metals"; "Further Researches on the Butter of the Cow," by Mr. J. A. Wanklyn."

SOCIETY OF ARTS.—Monday, March 2nd, at 8 p.m. Cantor Lecture III., on "The Electric Transmission of Power," by Mr. Gisbert Kapp, M.Inst.C.E. Wednesday, March 4th, at 8 p.m. Paper to be read: "Modern Flour Milling," by Mr. J. H. Carter.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, March 2nd, at 8 p.m. Special general meeting.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, March 3rd, at 8 p.m. Ordinary meeting. Paper to be read, with a view to discussion: "On the Subterranean Water in the Chalk Formation of the Upper Thames, and its Relation to the Supply of London," by Mr. J. T. Harrison, M.Inst.C.E.

OWENS COLLEGE UNION ENGINEERING SOCIETY.—Tuesday, March 3rd, at 7 p.m. Paper to be read: "Hospital Buildings," by Mr. F. W. Maxwell.

PRICES CURRENT, 25TH FEBRUARY, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The market has continued steady during the week. No change of importance has taken place, and business continues of a limited nature. Stocks decreased about 1,000 tons during the first fortnight in February. Chili bars are about 2s. 6d. higher than last week, quotations to-day being £53 2s. 6d. to £53 10s. cash, with steady business. Manufactured, £65, "strong."

TIN: Firmer, with improving prices.

LEAD: Steady, prices unchanged.

SPELTER continues to advance, supplies being limited and most producers fully sold for some months ahead. Prices on the Continent are higher than in England, so that there is every likelihood of a further rise in price.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Prices of all "Union" articles are firmly maintained, and bleaching powder is more active. In sulphate of copper some heavy sales have been made, and the article is now firmly held at an advance of 15s. to 20s. per ton. Sulphate of ammonia is easier, and little business is being done at present. Carbolic acids are unchanged, but there is less pressure to sell crude, the production being now considerably reduced. Benzoles are easier. All qualities of sulphur are in active demand.

DIRECTORY OF PAPER MAKERS OF THE UNITED KINGDOM. London: MARCHANT, SINGER, & Co.—This useful directory contains an alphabetical list of the names of paper manufacturers, with a list of the different sorts of paper made at each mill. There is also an alphabetical list of mills, a classified list of different makes of paper, and a list of the water-marks used by paper makers and wholesale stationers.

THE INSURANCE YEAR BOOK, 1891. London: SIMPKIN, MARSHALL, & Co.—This book, which contains a complete list of the life assurance companies carrying on business in Great Britain, has a preface, in which the history of life insurance, the nature of a policy, the calculation of the premium, the conditions of the contract, the division of profits, and surrender values are all fully explained. There is also a note which gives an explanation of the summary of valuation returns, and other tables. Under the head of each company there will be found tabulated returns giving the total income and total outgo during the past five years.

HOME INDUSTRIES.

LONDON, 26th February, 1891.

The Money Market.—The money market remains firm, but without any distinguishing feature. The efforts of the Bank to strengthen the general monetary position of the market have proved fairly effective, and the drain of gold for abroad has greatly diminished. Business in the stock markets is still on a very small scale, and there are no indications as yet of a revival. Colonial Government stocks have been firm in the expectation of legislation to add them to the list of securities in which trust funds may be invested, and investment stocks generally have been in request. Home railways are idle and irregular, and American rails are by no means brisk. The market for foreign bonds keeps fairly good, and there has been a recovery in Argentine values after a fresh decline. Silver securities are drooping, although the low price of the metal has stimulated purchases of it. A fair business is transacted in mining shares, but industrial and miscellaneous securities present no features, unless it be the constant fluctuations in Bell's asbestos shares.

The Junior Engineering Society.—At a meeting of this Society on the 20th inst. papers were read by Mr. J. B. Ball, on "Carriage Way Pavements in Large Cities," and by Mr. Albert Wollheim, on "The Design and Construction of Sewage Precipitation Works." Mr. Ball briefly described the essential features of a good carriage way pavement, pointing out the absolute necessity of a proper foundation. The present systems of paving were described, and it was stated that the Improved Wood Pavement Company had laid nearly 3,000,000 square yards of their paving. In Berlin the use of asphalte had increased between 1880 and 1887 from 127,000 to 655,000 square yards, and in London between 1883 and 1889, over 60,000 square yards of wood had been relaid with asphalte. Mr. Wollheim, in his paper, dealt with the design of sewage precipitation works and pumping machinery, and various apparatuses for adding the chemicals, and pointed out the necessity of each apparatus being automatic in its action. Some recent important experiments by Mr. Lindley, M.Inst.C.E., of Frankfort, on the displacement of water in tanks were referred to, and the principles of the design of settling tanks were considered.

New Screw Steamer for the Congo.—A new screw steamer, of a type suitable for work on the Congo, is to be built by Messrs. J. I. Thornycroft & Co., of Chiswick, for the Baptist Missionary Society. The vessel will be similar in construction to the "Peace," which had a draught of only 1ft., and will be placed at Stanley Pool, where it is to be used for mission work. The method of screw propulsion has been chosen in preference to that of paddle wheels, as the machinery is lighter and more readily transported overland to its destination. This type is perhaps better than the stern-wheel steamer, which necessitates the boiler and engines being placed at the extremity of the vessel, and thus causes an increased strain. The management of the vessel can be carried on from the upper deck, the steam valve and reversing levers being under the control of the missionary who has charge of the vessel. The dimensions of the vessel are 84ft. in length by 13ft. in breadth, and when loaded she will have a draught of 2ft. 2in. The vessel is to be provided with the Thornycroft water tube boiler, which can be easily transported overland, and quickly put together again when the parts are brought to their destination.

The West End Safe Deposit.—On the 21st inst. we had an opportunity of inspecting a safe deposit which has been opened by the Security Company, Limited, at 63, St. James's Street, S.W., and constructed by Messrs. Chubb & Sons, of 128, Queen Victoria Street, E.C. This firm are also erecting for the same company safe deposits in Birmingham and Glasgow. The West End Deposit, though not as yet so large as others in London, is exceedingly strong, being constructed of "compo" steel, 1¼in. thick, which is said to be absolutely undrillable. The principal compartments are a large safe deposit chamber, containing small safes or "pigeon-holes," a strong room for chests, fireproof throughout, and three small strong rooms, which will be let singly. The main entrance door to the large chamber, of which we hope to give an illustration in a later issue, is of massive proportions, weighing about two tons, and is built up of "compo" steel. It is secured by sixteen massive bolts, weighing nearly a quarter of a ton. Three locks are provided—viz., a patent detent lock, a change key lock, and a triple "time" lock, the latter of which will run any length of time up to seventy-two hours. These locks are fitted upon an internal spring plate, so that in case of an explosion from the outside, the concussion will be reduced to a minimum.

Institution of Mechanical Engineers.—The summer meeting of this Institution in the present year will be held at Liverpool in response to a cordial invitation received from the Mayor, Mr. Joseph B. Morgan, Assoc.Inst.C.E. and Assoc.Inst.Mech.E., on behalf of the local members of the Institution, the leading engineers, shipowners, and merchants, and other influential residents in the city and neighbourhood. The meeting will commence on the 28th of July, and will last four days.

MANCHESTER, 26th February, 1891.

A New Steam Trap.—Mr. J. J. Royle is introducing a new form of steam trap which is simple and effective. It consists of two hemispherical shells of cast iron, each of which is provided at its crown with an orifice. Within the sphere formed when the two pieces are bolted together, a copper ball is placed, and a spindle is carried up from it and passed through the upper orifice. The steam is admitted at the side and the water escapes by the lower orifice, fitted with a valve which is closed by the downward pressure of the ball. By an ingenious arrangement or proportioning of the upper orifice, the ball is put in equilibrium, and readily rises as soon as water accumulates. In this way the valve is opened, being speedily closed when the water is cleared. The new trap is very simple and compact, and is notable for the novelty of its construction.

The Prospects of the Ship Canal.—In the course of an address delivered in Salford, on the 24th inst., Mr. Marshall Stevens gave a number of interesting figures of the trade prospects of the above undertaking. After pointing out that there was practically quay space along the whole length of the canal, and that at the Manchester end alone there was dock accommodation greater than in the whole port of Cardiff, he went on to deal with the statistics of the subject. The whole of the foreign and colonial trade of the United Kingdom amounted in value to £742,343,336, of which £299,679,804 was shipped or received *vid* Liverpool and the Humber ports. The imports of food stuffs into the country amounted to 1,186,072 tons, and of raw material to 8,516,713 tons, while the exports of such materials as are manufactured or obtained in this district amounted to 28,674,392 tons. Considering that 7,000,000 persons would be served by the canal, it was certain that a large proportion of the above quantities would be carried by it, and it was further worth noticing that the magnificent navigation on the Clyde only served a nation with 3,734,700 people. About 1,000 tons of bale and case goods left Manchester daily, much of which would undoubtedly be shipped direct. Practically the whole of the salt trade would pass over the canal, and the coal trade of both Lancashire and South Yorkshire would be benefited, Manchester being the nearest shipping port for many of them.

The Engineering Trades.—Although there is still a large amount of business, there is a very perceptible decrease in the number of new orders. Many signs are to be noted of a diminished trade, and it is quite apparent that the extension of the cotton spinning industry has practically reached its limit, although it is true that many new mills are being erected. In the machine tool trade extensions are numerous. Messrs. Smith & Coventry, Limited, are carrying out a very important enlargement of their works, and Messrs. Hulse & Co. are about to commence work in a new shop, which, despite the recent large extension of their premises, has become necessary. This erecting shop is 120ft. long and 35ft. wide, and is fitted with a 25-ton overhead power travelling crane of special design, which is so arranged that the crab can be brought close up to the pillars carrying the gantry. A clear lift of 26ft. is given, this being necessary to take in the large standards of the combined vertical and horizontal planing machines made by the firm. The firm are just completing some very heavy tools, among which is a large massive planing machine for armour-plate work, and a punching and shearing machine for 1¼in. steel plates. In textile machine works much activity still prevails. Messrs. Ashworth Bros., of Manchester, are about to commence a large branch establishment in the United States for the manufacture of their well-known specialties. The land has been acquired by them near Fall River, and the project is to be pushed forward.

New Type of Oil Engine.—Messrs. Crossley Brothers, Limited, Openshaw, Manchester, delivered their first oil engine last week, a 4-horse power nominal indicating about 9½ h.p.

The Linen and Jute Trades.—The home trade still suffers from the various adverse influences which have been mentioned from time to time, and there appears to be little, if any, prospect of an immediate change for the better. As regards the shipping department, the aspect of trade is unfavourable. A private cablegram to a Portland Street shipper from Valparaiso, says: "Stop all goods, pending further news." Exchange is at 16¾d. for 90 days' bills. For the Chilian importer there is an extra burden on that account of over 100 per cent., owing to the fluctuations in the price of silver. The Eastern markets are very dull at the present time, while here also the rate of exchange has a deterrent effect. Prices of linens generally are fairly steady. Hessians are unchanged, but the position of buyers is strengthened owing to the determination of the Calcutta Jute Manufacturers' Association to resume running full time.

GLASGOW, 26th February, 1891.

Pig Iron.—The total number of furnaces in blast last week was fourteen. There are altogether 140 furnaces in Scotland, and in ordinary times from 80 to 100 of these are in blast. During the past four months only six have been in blast. In spite of the increased production yielded by the eight additional furnaces, and the prospect of a general resumption of production, the price has stiffened, and that not in consequence of speculation, but of a legitimate trade demand. This is in many ways an encouraging sign. The recent history of the Scottish iron trade affords a remarkable instance of the astuteness with which the iron manufacture is carried on. The furnaces were blown out and production stopped just at the time when demand had definitely slackened, and when prices began to show a downward tendency, and the obvious meaning of the movement was cleverly disguised by seizing the occasion of dissatisfaction among the furnacemen to effect what was in reality a lock-out. A week or two ago, before the increased demand was visible to those outside, the makers began to resume production, and before the furnaces are fully in blast find themselves making for a rising market. The series of events shows the shrewdness of those who administer the huge concerns connected with the iron trade of Scotland. It remains to be seen, however, whether the demand which has already influenced the trade to a small extent will be maintained.

Labour Troubles.—The most important labour dispute pending is the strike of blast furnacemen, which has already lasted about five months, and is now going on without any sign of a settlement. The demands of the men involve practically the assimilation of the Scotch to the English system of working. They demanded originally an eight-hour shift, with extra pay for Sunday duty. They seem, however, to have narrowed their demand to the latter point, and are now understood to be holding out for time and a half wages for Sunday. The ironmasters have met this with the announcement that they refuse to give extra pay for Sunday, and that they intend reducing the rate of wages by 20 per cent. The men have offered to submit the question of wages to arbitration, and have intimated that, should the state of the market show a reduction in wages to be necessary, they will accept it, but that they cannot forego the claim for extra pay as regards Sunday duty. Meanwhile, Messrs. Dixon & Co. have relighted a portion of their furnaces, and have secured a number of men to take the places of those on strike.—On the 24th inst. the boilermakers employed by Messrs. Scott & Co., Greenock, numbering about one hundred, struck work on the ground that one of their number had been dismissed owing to his having refused to work during the night. It seems that there is a union rule against night work, excepting under special conditions, and the case named is alleged to have been in contravention of this rule.

Engineering and Shipbuilding.—There is still a lack of orders in local engineering and shipbuilding circles. Some of the larger establishments have, however, still large contracts which are keeping them employed, though there is a dearth of new orders to replace these as they are worked off. The smaller concerns are fairly busy, though with work of no great magnitude. There are, nevertheless one or two heavy contracts for engineering material, for which Glasgow firms are at present quoting. Messrs. Wm. Arrol & Co. are making rapid progress with the material for the superstructure of the Tower Bridge. The columns, girders, and ties are built and drilled in position in the yard before being despatched to London for erection. The drilling is being done partly by rope-geared multiple drills as used on the Forth Bridge contract, and partly by electrical drills. These are worked by a "Manchester" dynamo and motor, and have been applied most successfully to this particular work. The riveting will, of course, be done by Messrs. Arrol & Co.'s well-known hydraulic riveter. As an instance of the fluctuating character of the earnings of shipbuilding firms, it is to be noted that Messrs. W. B. Thomson & Co., Limited, engineers and shipbuilders Dundee, have last year earned a profit of under £90, exclusive of a payment for interest, which causes the year's working to show a loss of about £1,000. There remained, however, a balance of undivided profits at the beginning of the year's work of £3,700, and to this sum Mr. Thomson has added sufficient to pay a dividend of 6 per cent. on the capital, according to the terms of his agreement with the company. The prospectus of Messrs. Merry & Cunninghame (Limited), to which reference was made last week, has now been issued. The capital is £250,000 in shares of £10 each, one half of the capital in preference and the remaining half in ordinary shares.

(From our own Correspondents.)

LIVERPOOL, 25th February, 1891.

The Mersey Bar.—The dredging operations which have been conducted for many months, with the object of removing the bar at the mouth of the Mersey, have so far been quite unsuccessful. Although 117,000 tons have been removed by the suction dredgers, recent surveys have shown that this amount has made no appreciable difference in the depth of the water over the bar. This result verifies the opinion of experts, who were of opinion that dredging operations, to be effective in this particular case, should only be adopted as an auxiliary to permanent works. If these operations are continued it is probable that the £20,000 voted by the Dock Board will be expended in vain.

The Atlantic Cattle Trade.—With regard to the investigation now being made as to the accommodation for cattle upon board the steamers, and the methods of embarking and discharging the cargoes of live stock, it may be noted that the steamer "Alexander Elder" has just arrived, after a stormy voyage, with 790 head of cattle on board without losing a single head, and that during the last few months she landed over 7,000 head of cattle with the loss of only eight animals.

SHEFFIELD, 25th February, 1891.

Iron and Steel.—A steady amount of work continues to be turned out here, but there is not so much overtime worked as was the case six months ago. The demand for railway material is still active, and a fairly large order for

Digitized by Google

rails has been placed. Sheffield is able to produce the best steel rails at a low price, and, with a free entry into Continental ports, would do a good business. Rolling stock builders expect some large orders for coal waggons from the home railways, most of whom, it is said, will be compelled to adopt the Midland Railway's policy of owning their freight trucks. The trade in steel castings is very quiet, but the cause of this is not apparent, as the shipbuilding and other heavy trades are fairly brisk, and these are usually the best customers for castings. Leeds engineers continue to draw their material in great part from Sheffield, but they sometimes give a large order to Germany, especially when they want it very cheap and the testing is not too severe. Some very heavy machine tools, as well as cranes and hydraulic plant for special work, have been supplied by the leading makers in Leeds. Local engineers continue busy mainly on work given out last year, and the small firms employed in making drilling machines, ratchet braces, spanners, taps, and dies are doing a brisk trade.

ELECTRIC LIGHTING AT BARNSLEY.—The Corporation have applied to the Board of Trade for sanction to borrow £23,000, to be applied for electric lighting purposes. With regard to overhead wires, the Board of Trade say that, while they are very unwilling, in the case of a permanent installation, to approve of a system in which overhead lines are used, in deference to the wishes expressed by the Corporation, they will not decline to approve of the proposed system in the present case. It is estimated that an additional £20,000 would be required to place the wires underground.

GENERAL.—The general trades of the town are fairly good, but a few of the cutlery hands are idle owing to the closing of some markets abroad, mainly in the United States. Silversmiths and electro-platers are busy, and Messrs. Mappin & Webb, one of the leading firms, are extending their plant considerably. Taken as a whole the Sheffield trades may be said to be good.

DREDGING MACHINERY.—A large consignment of dredging machinery has recently been shipped for the Spanish Government from the works of Messrs. Rose, Downs, & Thompson, of the Old Foundry, Hull, comprising five of their largest D-size "Kingston" dredgers, for fixing to the decks of ordinary wood floats, for use in the Philippine Islands, and a large hopper barge, fitted with a "Kingston" dredger and compound surface-condensing engines and marine boiler, for use at the Spanish Arsenal at Carraca, Cadiz. The whole of this order has been shipped in pieces for re-erection abroad. The work is of the highest class, and has been completed under the personal inspection of Captain J. Alvarez, S.R.N., the naval architect to the Spanish Royal Naval Commission in London. We understand that these orders were obtained by Messrs. Rose, Downs, & Thompson in direct competition, and it is expected that further orders will follow as a result of the satisfactory tests.

BIRMINGHAM, 25th February, 1891.

GENERAL.—Business generally continues quiet. In the iron trade inquiries are few, and there are not many orders. Eastern buyers are pressing for delivery of orders already placed. "Marked" bars are still at £8 per ton at works, with £1 10s. extra for "Best," and £2 10s. extra for "Best Best." Some few specifications are being taken for common iron bars at £6, and cable bars at £6 7s. 6d. per ton. Cinder pig is being sold at 40s. per ton, hot blast at 70s., and cold blast at 95s. to 100s.

CHAINS.—Chain and cable makers are still fairly well employed, but report that fresh orders are very scarce. The Lloyd's Proving Houses at Tipton and Netherton are full of work. All cables for ships are tested at these houses according to Act of Parliament, and the users of short link crane and incline chains seem disposed to insist on having certificates from the same authorities. It would, perhaps, be wise for Parliament to pass an Act to control the inspection and testing of all crane and other chains.

LEICESTER, 25th February, 1891.

COAL MINING.—There has been some decrease in the number of orders. The collieries are working less time than they have done for a considerable period. The stocks on hand are very low, and prices are in consequence well maintained. Coal owners are very firm in resisting concessions in view of large contracts. The pottery and tile works are all well employed.

WOOL SPINNING AND YARN TRADES.—The local wool market is feeling the effects of the late London sales, and prices are fully maintained. There has not been a large amount of business in the past few days. Indeed, it is somewhat inactive, though there is a steady consumption. The business done is for present needs, and speculative operations are quite absent. Average deep-stapled fleeces make 22s. 6d. to 23s. 6d. per tod; superior lots, 24s. to 25s. per tod; choice lots, majority Shropshires, 26s. to 27s. per tod. Spinners are not very busy, and orders taken are at barely remunerative prices.

BOOT AND SHOE TRADE.—There has been a further accession of business, and generally this industry is in better condition, but the amount of trade does not yet reach the average of last year. Though there is an absence of great pressure, workpeople are fairly well employed. Leather merchants are doing more business, but buyers are cautious, anticipating a fall in the market. There are, however, no indications of there being any decrease in current quotations.

SWANSEA, 25th February, 1891.

PUBLIC WORKS.—The Swansea County Borough Council are seeking to borrow £88,000 for works of sewerage and water supply.—The London and North-Western Railway Company have offered to spend £20,000 in replacing their present tips at the Swansea South Dock by the most recent appliances, but they stipulate that the Trust shall deepen the entrance to the dock. A scheme to render the River Tawe navigable might contribute to this end. The idea was considered impracticable fifty years ago owing to the freshets in the river, but it is contended that the scheme is not beyond modern engineering skill. If carried out it would give Swansea a floating harbour all the way up to the weir at Morriston, and although it would probably cost £200,000, the improvements would result in a permanent saving to the Trust.

CLOSING OF IRON AND STEEL WORKS.—In a few days the Rhymney Iron Works will be closed, and the directors of some of the other large iron and steel works in the district are talking of blowing out their furnaces owing to the high price of fuel and labour, which makes profits impossible.

CARDIFF, 25th February, 1891.

IRON AND STEEL.—The pig iron market is still depressed, and prices show no improvement. The inquiry for steel rails is very poor, and at the Rhymney Works it has been decided to suspend operations at the rail mill. In the iron ore trade, Rubio of good quality is quoted at 14s. c.i.f. Cardiff or Newport, 14s. 3d. Swansea, 15s. Port Talbot, 14s. 9d. Porthcawl, 15s. 6d. Glasgow, 15s. Tyne, 15s. 3d. Tees.

COAL AND COKE.—The condition of the steam coal market this week is not so satisfactory as in recent weeks, a natural result of the possible development of labour disputes. Steam coal is weaker, although a number of colliery owners are so well supplied with orders that they have not been forced to follow the downward tendency. Current quotations are:—No. 1 quality, 14s. 9d. to 15s. 3d. f.o.b.; No. 2 quality, 13s. 9d. to 14s. 6d. f.o.b.; No. 3 quality, 13s. 3d. to 13s. 6d. f.o.b.; No. 4 quality, 12s. 6d. to 13s. f.o.b. Small steam coal, 5s. 6d. to 5s. 9d. For house coal there is a brisk demand at rather lower figures, 13s. 9d. to 14s. being the ruling figure for No. 3 Rhondda, and 12s. 6d. for No. 2. Patent fuel realises 13s. 6d. to 13s. 9d. In the coke trade one or two export orders have come to hand for furnace coke, which is quoted at 19s. 6d. to 20s. 6d. f.o.b.; foundry, 21s. 6d. to 22s.; best foundry, 24s. to 27s.

INSTITUTE OF MARINE ENGINEERS.—The Senatus of the University College of South Wales and Monmouthshire has granted to the members of the Bristol Channel Section of the Institute of Marine Engineers the free use of certain rooms, for the purpose of meetings, in the University College, Cardiff. A resolution was passed at a meeting of the local members of the Institute in Cardiff to the effect "that the best thanks of the Institute of Marine Engineers be given to the Registrar and Council of the University College of South Wales and Monmouthshire, for granting us the free use of rooms in the college for the purpose of holding local meetings." Professor Elliot has been elected chairman.

THE BRITISH ASSOCIATION MEETING.—The following list of nominations has been made for the Sectional Presidencies for the Cardiff meeting, which will commence on the 19th of August next:—A (mathematics and physics), Professor O. J. Lodge; B (chemistry), Professor Roberts-Austen; C (geology), Professor T. Rupert Jones; D (biology), Mr. F. Darwin; E (geography), Mr. E. G. Ravenstein; F (economic science), Rev. Dr. Cunningham; G (mechanics), Mr. T. Forster Brown; H (anthropology), Professor Max Müller.

BARROW-IN-FURNESS, 25th February, 1891.

HEMATITE.—There is but a small business doing in hematite pig iron. Prices have improved, owing to the clearance of stocks of hematite warrants for consumptive purposes to the extent of 3,726 tons, leaving the stocks still in hand at 209,482 tons. Hematite warrants have changed hands at 50s. 10d. net cash, but makers are still asking 53s. per ton for Bessemer mixed numbers net f.o.b., and complain that they cannot make a profit with raw material at its present cost. Iron ore is in less request, being at 10s. 6d. to 11s. 6d. per ton net at mines, and East Coast coke is still firm at 21s. to 22s. per ton delivered at the furnaces. Another furnace has been blown out at the West Cumberland Works, where only one out of six furnaces are in blast. Forty-one furnaces are blowing in the North-West district, and 35 are idle, 8 being idle in Furness, and 27 in West Cumberland, although 48 furnaces are built in the latter district, and only 28 in the former. The reason for this curious position is the fact that makers are much better employed in Furness than in Cumberland, at Barrow alone 12 of the 14 furnaces being in blast.

STEEL.—There is less activity in the steel trade, and although a few orders for rails have been placed during the week, the outlook is not cheerful, nor is it at all likely that the mills will be busily employed throughout the season; in fact, in West Cumberland the mills are only on short time, and at Barrow this week, for the first time over a long period, the mills did not start till Tuesday morning. Prices are unchanged, with rails at £4 15s. for heavy sections.

MIDDLESBROUGH, 25th February, 1891.

PIG IRON.—There was a large attendance at the weekly market held on 'Change, and a more cheerful feeling prevailed. The improved shipments indicate a better demand, and have had a favourable effect upon prices. Merchants ask 42s. 3d. for No. 3 G.M.B., buyers offering from 42s. to to 42s. 1½d. Cleveland warrants are 42s. cash buyers. In hematite, East Coast brands are 54s. per ton f.o.b. mixed numbers, sellers; West Coast brands are 50s. 9d. cash buyers, sellers 1½d. more. The stock in Connal's store on the 23rd inst. amounted to 123,373 tons, being an increase this month of 367 tons.

SHIPMENTS OF PIG IRON.—These are very favourable this month, amounting till the 23rd inst. to 60,094 tons, as against 31,338 tons to the 23rd of last month, and 32,921 tons to the 23rd of February, 1890. Scotland took 32,220 tons; other parts of England and Wales, 6,775 tons; and foreign countries, 21,099 tons. The main improvement is to Scotland, but the increase is general, and there is a very hopeful prospect.

MANUFACTURED IRON AND STEEL.—Prices are unchanged, but inquiries are fewer and the prospect rather duller. Some large orders have been placed lately for railway material, but they are said to have been taken at very low prices. Iron ship plates, £5 15s.; angles, £5 12s. 6d.; bars, £5 15s.; steel ship plates, £6; angles, £6 5s.; rails, £4 17s. 6d. per ton, all less the usual discount and on the usual terms.

NEWCASTLE, 25th February, 1891.

THE COAL TRADE.—In connection with the Northumberland coal trade a hopeful feeling exists, but it appears to have no better foundation than the possible development of labour complications elsewhere. The output at the pits is being increased, and the tendency to firmness in prices is somewhat strengthened. The shipments of coals and coke at Tyne Dock during the week ending the 21st inst. amounted to 104,673 tons, being a decrease as compared with the corresponding week last year of 3,012 tons.

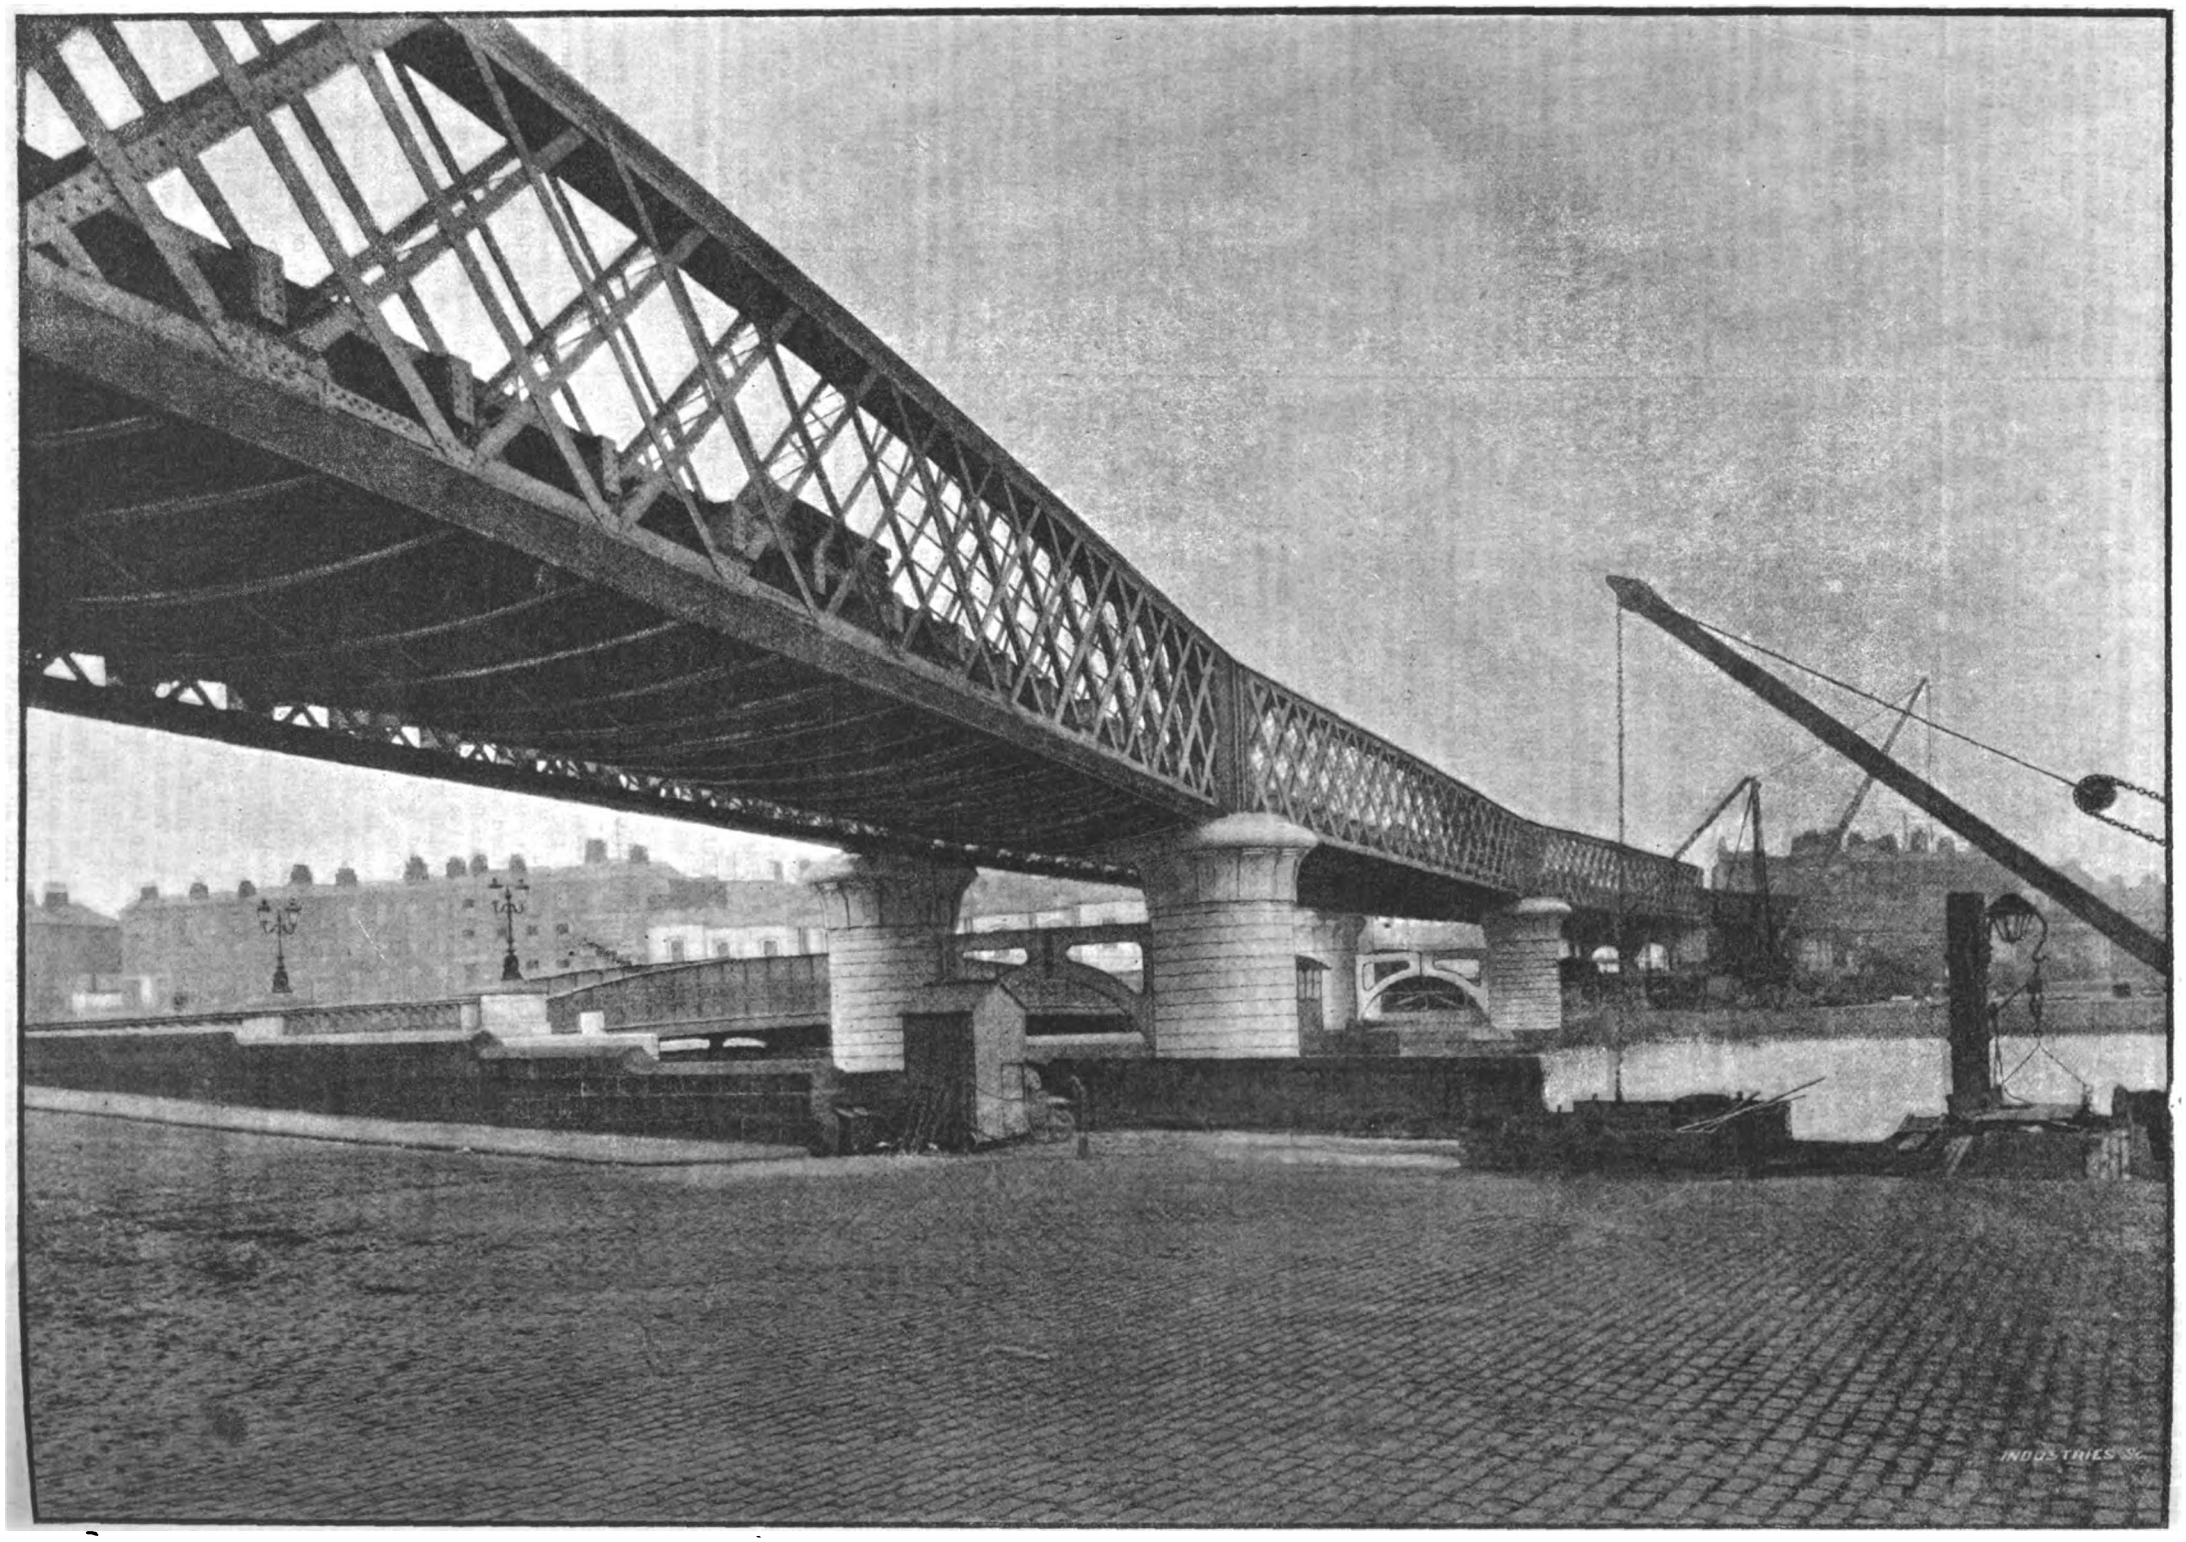
SHIPBUILDING.—Though the pressure of work in most of the yards is diminishing, and the feeling in commercial circles is somewhat despondent, it is a hopeful sign that, in addition to some foreign orders for tonnage that have been secured in this district lately, one or two important contracts have also been obtained from English shipowners. Among these may be mentioned an order for a vessel of superior type, which is to have a carrying capacity of 7,000 tons. This order has been obtained by Messrs. C. S. Swan & Hunter from a leading Hartlepool shipowning firm. The engines and boilers for this vessel have been ordered from the Wallsend Slipway and Engineering Company, Limited, and they will be constructed on the latest principles, with a view to the attainment of high speed combined with economical consumption of fuel.

NEW COMPANY.—The old-established firm of Messrs. T. & W. Smith & Co., shipbuilders and repairers, North Shields, has been converted into a limited liability company, under the style of the Smith's Dock Company, Limited. Under the newly constituted company it is proposed to further develop the business by adding a pontoon dock and suitable premises for the carrying on of engine repairing. Some time ago the probability of a pontoon dock being provided at these works was mentioned in this column, and it is satisfactory to find that the prediction then made, on the strength of information received at the time, is likely to be fulfilled.

THE TIMBER TRADE.—Just now there is but little timber being imported, and at the docks nothing is being done, except the forwarding of numerous lots of mining timber to the various collieries. At the sawmills business is fairly active; the brisk state of the local building trade is causing a large demand for sawn timber and mouldings.

DUNDEE, 25th February, 1891.

JUTE AND FLAX TRADES.—Neither branch of the local industry presents any new feature of interest. Last week prices of jute were low, in consequence of a low exchange, but buyers did not operate freely. Little further reduction is looked for, and a rise of prices yesterday is attributed to the increased disposition to buy shown by spinners. Cable advices from Calcutta report that prices of loose jute are firm, and that the market for baled jute shows an upward tendency. In the local market yesterday there was more business done both for distant and in spot parcels, and the market was firmer. Jute yarns are firmly held, and there is considerable inquiry. There is a fair demand for jute goods from the United States and Canada. Cablegrams from New York report a firm market there, burlaps 40in. 10½oz. being quoted at 5 1/16c. per yard, and light weights at 4¾c. per yard. The political disturbances in Chili and Argentina exercise a disturbing influence on the South American trade The market for flax and tows has been quiet, but there are some indications of improvement. In Fife yarns transactions are reported to be fairly numerous, but other sorts are quiet. There is a pretty good home demand for linens, but there is room for improvement in the foreign inquiry. Sailcloth is dull, and some curtailment of production is expected.



NEW RAILWAY.—The first sod of a new railway, which is to run from Crieff to Comrie, was cut last week. The contracts amount to £30,000, and the total cost of the undertaking is expected to be about £40,000. The distance of Comrie from Crieff is between six and seven miles.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 399, Strand, London, W.C.*

FRIDAY, 27TH FEBRUARY, 1891.

THE BOARD OF TRADE AND RAILWAY RATES.

THE Board of Trade have this week introduced into Parliament their Bill to confirm the provisional order recently made by them under the Railway and Canal Traffic Act of 1888. It is not too much to say that no more important measure, as affecting trade and industry, has ever been presented for the consideration of the House of Commons. The Railway and Canal Traffic Act of 1888 mainly dealt with general principles, which were enunciated in the various enactments that the Act called into operation; but this is a matter that deals essentially with details, and it is detail that mostly concerns both the railways and the traders in their everyday relations. The new Bill does not go quite so far as the traders generally would desire, but it goes much farther than the deposited schedules of maximum rates and charges, and the proposed classification of goods and mineral traffic submitted by the companies themselves, in accordance with Section 25 of the Act of 1888. It even goes farther than the proposals contained in the Report of the Commissioners of the Board of Trade, made in July last, for it has been found expedient to make essential modifications of both station and service terminals, as specified in that Report. What, however, is still the main blemish of the Bill, in the view of traders generally, is the recognition of station and service terminals, against which traders as a body have urgently fought. The maximum station terminal is defined in the Bill to be "the maximum charge which the company may make to a trader for the use of the accommodation (exclusive of coal drops) provided, and for the duties undertaken for which no other provision is made in this schedule by the company, at the terminal station for, or in dealing with merchandise, as carriers thereof, before or after conveyance." This clause is, of course, a distinct acknowledgment of the right of a railway company to make charges other than those authorised in their schedules for conveyance, without reference to services actually rendered. In other words, the Board of Trade authorises separate charges for the use of premises that the traders have always regarded as, and maintained to be, an integral part of the railway. But when we come down from the recognition of the principle of station terminals to the consideration of their details, we find that the traders have not quite so much cause for dissatisfaction. The station terminal proposed by the London and North-Western Railway Company, in their deposited schedule, was 1s. 4d. for Class A, 2s. for Class B, and 2s. 6d. for Class C traffic, including both ends. The Board of Trade originally proposed that these terminals should be reduced to 1s., 1s. 6d., and 2s., including both ends, but this proposal having been resisted by the traders, the Bill now before Parliament has been so far modified in respect to terminals that the station terminals proposed are only about one-half of those originally proposed, being 6d. per ton for Class A traffic, 1s. per ton for Class B traffic, and 2s. for Class C traffic, including each end. The station terminals proposed for the other classes—that is, from Class 1 to Class 5 inclusive—are 1s. 6d. at each end, or 3s. in all, whereas, in the original schedules of the London and North-Western Railway Company, they were set down as 4s. between two large towns, 3s. 6d. between a large and a small town, and 3s. between two small towns. The terminal proposed for Class A, or mineral traffic, is as low as it could well be, if a terminal is to be allowed at all, and from this point of view, therefore, traders have not much reason to complain. The companies are entitled in this class to make a charge for the use of trucks, where these are provided by them and not by the traders, in addition to the maximum rates, which, in the Bill now submitted to Parliament, are the same as those proposed in the Report of the Board of Trade issued in July last. The comparative maximum rates in each class, under each set of schedules, are shown in the following statement:—

Class.	Ten Miles. L. & N.W. Ry.	Ten Miles. Board of Trade.	For Thirty Miles. L. & N. W. Ry.	For Thirty Miles. Board of Trade.	For Fifty Miles. L. & N. W. Ry.	For Fifty Miles. Board of Trade.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
A ...	0 10	0 9	2 6	2 2	4 2	3 7
B ..	1 8	1 1	4 7	2 11	6 11	4 10
C ...	2 1	1 5	5 10	4 0	9 0	6 8
1 ...	2 6	1 10	7 1	5 2	10 10	8 7
2 ...	2 9	2 3	7 9	6 3	12 1	10 6
3 ...	2 11	2 6	8 7	7 2	3 9	11 11
4 ...	3 4	3 0	9 10	8 8	15 10	14 5
5 ...	4 2	3 7	12 1	10 2	19 2	16 11

Here there is a considerable reduction in class rates all round, which cannot fail to be satisfactory to a large body of traders. But what is equally important is the fact that the traders have succeeded in getting the classification to a large extent recast. The iron and steel trades, for example, have had the bulk of their productions transferred from Classes 1 and C to Class B, and, although they did not succeed in getting pig iron placed in Class A, for which some of the principal traders contended, they have had a more than compensating gain in the transference of the bulk of their manufactures to a lower class than those in which they were originally placed. It has been much the same with other manufacturers. The Board of Trade has shown its readiness to listen to all reasonable representations affecting classification, and the general result has been a schedule which is certainly a great improvement upon that originally submitted by the companies. So far as service terminals are concerned, it has been a difficult thing for the Board of Trade to fix the amount to which the companies are fairly entitled in respect of operations beyond the mere conveyance of traffic. Those operations or services generally consist in loading and unloading, covering and uncovering. The following statement shows the amounts asked for in the companies' schedules, and the amounts proposed to be allowed in the Bill of the Board of Trade, the latter distinguishing the sum due in respect of each specific service, while the former simply lumped the whole amount claimed in one item:—

MAXIMUM SERVICE TERMINALS INCLUDING BOTH ENDS PROPOSED BY THE LONDON AND NORTH-WESTERN RAILWAY COMPANY.

Class.	Between Two Large Towns.	Between Two Small Towns.
	s. d.	s. d.
A } B }	A reasonable sum, subject to determination by the Railway Commissioners.	
C	1 6	1 0
1	3 0	2 0
2	3 6	2 6
3	4 0	3 0
4	5 6	4 0
5	7 0	5 0

Digitized by Google

MAXIMUM SERVICE TERMINALS INCLUDING BOTH ENDS PROPOSED BY THE BOARD OF TRADE.

Class.

A, B { Such reasonable sum as, in case of difference, shall be determined by an arbitrator appointed by the Board of Trade.

	Loading.		Unloading. At Each End.		Covering.		Uncovering.		Total.	
	s.	d.	s.	d.	d.		d.		s.	d.
C	0	3	0	3	1		1		0	8
1	0	5	0	5	1·5		1·5		1	1
2	0	8	0	8	2		2		1	8
3	1	0	1	0	2		2		2	4
4	1	4	1	4	3		3		3	2
5	1	8	1	8	4		4		4	0

There is not so much difference between the service terminals proposed by the companies and those appointed by the Board of Trade as is found in the station terminals, and in the terminals sought for in Classes A and B by some of the companies. The Board of Trade, however, proposes to allow the traders to perform such services for themselves if they desire to do so, and thereby gives them the opportunity of avoiding making any payment if they think the amounts excessive. To these terms the traders can hardly offer any reasonable objection, and it is more than probable that in practice, except with very large traders, who are concerned in having their work done in a particular way and within short limits of time, the railway companies will get the business that comes under the head of service terminals to do as hitherto.

It is probable that there will be a great fight in the future over the whole question of railway rates and charges. The railway companies are far from satisfied with the Board of Trade proposals. They speak of them as confiscatory, and have apparently determined to resist them to the utmost. The Bill will, therefore, when referred to a Select Committee—as it is practically certain it will be—have its provisions and proposals as hotly contested as the original schedules were when under the consideration of the Board of Trade Commissioners. But it would be a matter for regret if the whole ground had to be gone over again, and it is to be hoped that the Government will be able to devise some method of dealing with the Bill whereby this expensive and inconvenient course may be avoided.

PROPOSED LABOUR COMMISSION.

EXCEPT for the amount of information which such an inquiry must elicit, it is difficult to see what purpose the appointment of a labour commission can serve. We have had a plethora of commissions upon labour, and each of them have published voluminous reports, useful certainly to the economist, useless almost altogether for practical purposes, excepting so far as the researches of the economist after filtering through many minds effects these. Factory Commissions, Trade Union Commissions, Depression of Trade Commissions, Sweating Commissions, Poor Law Commissions have all been more or less labour commissions, each after its kind. All authoritative information upon questions of this sort is no doubt valuable, or at all events contains some modicum of valuable matter; but much might be ascertained without the machinery of a Royal Commission which has not yet been ascertained. For example, there are no adequate statistics of the rates of wages available either for the present time or for any period. Nor are there any adequate statistics of the cost of living now or at any other period. The same applies to the rate of profits. Thus one of the elements essential to a thorough understanding of the problem of the relations of capital and labour is wanting. Either the question must be dismissed as incapable of solution by the study of materials of this sort—and there is some justification for this view—or these must be made the basis of some fruitful inquiry on the subject. But such an inquiry does not lie within the possible province of a Royal Commission. It is an inquiry which might be appropriately undertaken by the Labour Correspondent of the Board of Trade, or, better, by a competent statistician. There is indeed nothing that the Commission is at all likely to discover which would not in all probability be discovered and expounded more speedily and more accurately by some such competent and experienced hand as Mr. Charles Booth, or one of the other experts of the Statistical Society.

If the intention is to follow up the report of the Commission by a series of labour laws, whose all-embracing provisions would enclose us in a mighty legislative machine, then indeed the Commission ought to be opposed. It is possible, however, that, like many another Commission, its Final Report may be the end of it, and its ponderous blue-books remain only as a kind of photograph of our social state for the benefit of future generations. While this criticism may be urged against confidence in the outcome of the Commission, there is one subject connected with labour already dealt with by the legislature which ought decidedly to be investigated with a view at least to make the provisions of the law plain to the judges who have to administer it. The recent contradictory judgments—*e.g.*, by Mr. Justice Cave and by Mr. Bompas, Q.C.—besides many others, and the uncertainty of jury trials under the Conspiracy Act of 1875 show conclusively that the Act requires revision. Conduct regarded in one court as criminal, in another court is innocent. This ought not to be. Whatever the law is, it ought to be clear and distinct. A man ought to know the limits of his freedom, or to have the opportunity of knowing them. A proper codification of the law of master and servant, and a healthily critical and, so far as may be, unbiassed tone of public opinion during labour disputes is far more likely to be effectual than any number of Royal Commissions or labour laws. This involves, however, a greater amount of public enlightenment than we have at present. It is a long method, but it seems the best. Legislation has always the appearance of being a short and easy method; but here, as in many other departments, the longest way round may be the shortest way home.

THE RETIREMENT OF SIR RICHARD MOON.

THE half-yearly meeting of the proprietors of the London and North-Western Railway Company, which took place last week, although held in the ordinary course of business, marked an event which was not only of importance to the railway chiefly concerned, but also noteworthy in the history of railways generally. The event to which we refer is the retirement of Sir Richard Moon from the chairmanship. Sir Richard has been so long connected with the London and North-Western Railway, and has so impressed his personality on its management, that all who know anything about railway work immediately call him to mind when that railway is mentioned. His great business qualities, his attention to details, and his entire devotion to his work have given him a unique position among railway directors, and will make his place exceedingly difficult to fill. No doubt he had surrounded himself with an exceedingly able body of men, and we hope that Lord Stalbridge, who has been elected to his position, will, not only by his own energy and ability, but also by securing the goodwill and hearty co-operation of his staff, be able to carry on the business of the company with success, a condition which requires due attention to the interests of the shareholders, to the welfare of the workers in all departments, and to the convenience and safety of the public.

Mr. W. H. Smith, M.P., expressed in a graceful manner the feelings of the shareholders regarding the retirement of the Chairman. He reminded them that Sir Richard Moon had joined the company as director forty years ago, and that he was elected chairman over thirty years ago. In that position he was fortunate in finding the chief work of his life, and he devoted himself entirely to it, seeking neither honour in other directions nor profit in other employments. No doubt his highest reward was in the confidence which the shareholders continued to express in the direction of the company, and in the assurance that its affairs were being conducted with honesty, with integrity, with a perfect regard to the claims and interests of the shareholders, and at the same time with due regard to the duties the company had to discharge to the public and to its servants. He also found part of his reward in the success which attended the operations of the company, which was in great part due to him in co-operation with the able staff with which he surrounded himself. Success is measured not merely by size of dividends, but also by goodwill between the servants of such an immense company and its officers and directors and freedom from labour disputes. The London and North-Western Company has been exceedingly free from such disputes, and its servants have shown during periods of excitement and agitation that they can adhere to the interests of the company, a state of affairs which is due largely to the influence and spirit of the man having the leading control. The consequence has been that the company, notwithstanding vigilant competition, has made great and rapid progress. It has consequently been able to get along without much of that fighting which has disfigured some of our commercial undertakings, and which has lessened the confidence that the public had in them. It has retained the confidence of its workmen by the care it has taken of their interests. As an example of this, it may be noted that it contributes about £24,000 a year to their sick and benefit funds in various ways, and a payment is thus produced, due partly to the contributions of the company, but more largely to those of the men themselves, of £60,000 a year, which comes to about £1 per head for all employed by the company. The servants of every grade are thus made to feel, and they show that they feel, that their interests are cared for by the company, that the company's interests are theirs, and that, in point of fact, it is one large co-operative concern for the benefit of all who are interested in it.

Sir Richard Moon, in replying to the kind things said of him at the meeting last week, indicated the secret of his success. He devoted himself, in the first place, to the interests of the company, and took care that its honour and integrity were maintained, and that its promises were fulfilled. He surrounded himself with good officers and servants, and treated them fairly. He was thus able to make everyone in the service loyal to the company, and he expressed the opinion that there was not any society in this country, or in the world, as loyal to its employers as the staff of the London and North-Western Company. He had always tried to show that it was only by treating servants well and loyally—in fact, by being one of them—that we could expect faithful work, and he impressed this upon his officers. At his farewell meeting with them, he gave this advice: "Remember, first of all, you are gentlemen; next, you are North-Western officers. Whatever you promise you must perform, and, therefore, be careful what you promise, but take care you perform it." If the same spirit existed generally between employers and employed there would be less difficulty between capital and labour. We have, therefore, dwelt on the work of Sir Richard Moon, as having a most important bearing on the trade and industry of the country. Such men do far more good in their day and generation by liberal-minded example than specialists in any department of science, however distinguished, for they not only provide the means of living, but also show us how to live and enjoy life in the highest and best sense. We are sure that our readers will unite with the shareholders of the London and North-Western Railway Company in expressing the hope that Sir Richard Moon may long enjoy a well-earned rest in his retirement.

THE "JUBILEE" OF THE CHEMICAL SOCIETY.

OUR readers have been made aware (see *Industries*, Vol. X., page 116) that the Chemical Society had made arrangements to celebrate their "jubilee" this week. On the afternoon of the 24th inst. a meeting was held in the theatre of the University of London, at which the President (Dr. Russell) made an introductory speech, tracing the position of chemical science before the year 1841, and the steps which led to the formation of the Society in the February of that year. Early in this century, Dalton, Davy, Cavendish, and Wollaston upheld the position of chemistry in this country, but a period of apparent inactivity followed, which induced Mr. Robert Warington to issue a circular inviting persons to become members of the proposed Chemical Society. Mr. Robert Warington's contribution to the proceedings of the meeting this week was of especial interest, as he is the son of the Mr. Warington who was so instrumental in bringing about the formation of the Society. He had fortunately kept the letters which his father had received, and these he had arranged and tabulated in an album which he presented to the Society.

Professor Odling, of Oxford, followed with a short sketch of the development of chemical theory during the last fifty years, and the proceedings terminated with the presentation of addresses from the Royal Society, by Dr. John Evans and Lord Rayleigh; from the Pharmaceutical Society, by the President; from the Société Chimique de Paris, by M. Gautier; from the Deutsche Chemische Gesellschaft, by Dr. Will; from the German Society of Chemical Industry, by Dr. J. F. Holtz; and the reading of an address from the Russian Physico-Chemical Society and congratulatory telegrams from many distinguished foreign chemists.

In the evening a *soirée* was held at the Goldsmiths' Hall, at which was exhibited an unique collection of apparatus and specimens illustrative of the work of Gilbert, Hauckwitz, Sir Isaac Newton, Scheele, Cavendish, Sir Humphrey Davy, Thomas Young, Dalton, Sir John Herschel, Berzelius, and Faraday; together with that of past presidents of the Society, amongst whom were represented Thomas Graham, Brodie, Gladstone, Warren de la Rue, Frankland, Sir Frederick Abel, Sir Henry Roscoe, Gilbert, Perkin, Hugo, Müller, and Crookes.

On Wednesday evening the Fellows entertained the foreign delegates and guests from kindred societies at a dinner at the Hôtel Métropole, when the Marquis of Salisbury made an excellent speech on the scope and practical use of chemical science.

Letters to the Editor.

IS THE STUDY OF THERMODYNAMICS OF USE TO ENGINEERS?

To the Editor of "Industries."

Sir,—When I first read the question, "Is the study of thermodynamics of use to engineers?" asked by the letter of "Student" in your issue of the 9th ult., I found myself inwardly replying, "It depends upon the engineer!" for I have not yet forgotten the story of the legal witness who, posing as an engineer, turned out to be a maker of iron bedsteads; and one would scarcely hesitate to answer the question with a negative for him!

Probably what "Student" really wants to know is if the study of thermodynamics is of any use to *him*, since this is a very natural and certainly a more wisely definite inquiry than the more general one he puts forth. I am frequently being asked by puzzled students and beginners in the profession whether such and such branches of engineering study are of any use, and I have long ago given up answering such questions without knowing something of the training and knowledge of the questioner, and of his probable future work. Since one could not honestly and unreservedly give an affirmative reply to the inquirer with "Student's" question who was quite certain to limit his engineering work to some branch of hydraulics, such as the manufacture and working of turbines, any more than I am now able to fully assure a student friend, who, with a veritable passion for locomotives, and with a fixed resolve to work at nothing else, is puzzled just now to see how he is most usefully employing his time in the construction of dock walls and the design of turbines, on which his college course now necessitates his working.

Then, again, it is very desirable to recognise something of what is mutually meant by "thermodynamics," and what is to be the criterion by which to measure the use of its study. Some of your correspondents, notably those connected with education, have not failed to acknowledge that the advantage of a certain study is often found only in the mental exercise and power it affords, and your own article has pointed out the fitness of thermodynamics for such a purpose, but I imagine it is not this to which "Student" refers. If, then, we measure the use of an engineering study by its useful application in practical life, and hence, by the greater power and capability of the possessor, it is not easy to see wherein a knowledge of thermodynamics will increase the efficiency of an engineer who is never called upon to work on any operations where heat is a connected agent. On the other hand, to ask if an engineer engaged in the manufacture or superintendence of mechanisms depending for their utility upon the application of heat, either in air, or gas, or steam, is the better for a knowledge of the science of heat, because many men have made good engines without that knowledge, seems to me as wise as to doubt that an artist is the better for the study of perspective, because, forsooth, there are some artists who, without this study, can paint pictures which sell.

Since "Student's" letter was caused by a recent issue of Professor Cotterill's book, and by the varying opinions of its reviewers, one imagines he includes by "thermodynamics" the whole of the subjects considered in that work; but surely neither the writer himself nor the most ardent enthusiast for a liberal engineering education would assert that so extended a study should be a *sine quâ non* in the training of every engineer. That it is so included with very many is beyond doubt, and one has not much trouble to find, and in the front ranks of present day engine construction, some notable examples of the use of Professor Cotterill's teaching. But while the so-called necessary subjects in engineering training continue to increase in number and extent as they have done during the past few years, it will, I think, be a much-contested question as to how much time should be devoted to the more purely theoretical side of the subjects, as compared with the more practical side.

No engineering educational course can be made to exactly suit the needs of each student, and since time is limited, and the subjects many, one hears of considerable difference in the methods of teaching. Not long since a student from a well-known Midland Technical College, in singing the praises of his Professor, said to me "He gives us a formula for *everything*." This would mean, I suppose, that to get on to something useful, meaning thereby something practical, certain primary statements are taken for granted; and in the case of thermodynamics the student would not himself perform any experiments on the theoretical parts of heat, such as on specific and latent heat, absolute temperature, expansion of gases, mechanical equivalent, but would, after a few hurried formulæ lectures, proceed at once to practical experiments with the laboratory engine and make himself familiar with the efficiency of that engine at least. On the other hand, he may devote so much of his time to becoming master of principles that his course may be ended without their practical application ever being reached. Speaking generally, I am inclined to say that an engineer engaged chiefly in engine work cannot know too much thermodynamics, but as to how much he should endeavour to acquire consistent with a right proportion of other equally important subjects must, I think, be left to individual decision. Nor am I able to imagine any eminent engineer, whatever branch he may be engaged in, who can be ignorant of such fundamental principles of thermodynamics as (shall I say) the mutual conversion of work and heat, which covers so wide a ground.

I have thought it worth while to examine the examination papers set in "Steam" at the Science and Art Department examinations for the past ten years, in order to see what guide they would afford to the position of thermodynamics in the opinion of that learned body. I find that it would at all times have been possible to pass well in either stage without working a single question relating to thermodynamics; in some years the elementary stage contained no heat questions, while in no year did the heat questions in the advanced stage exceed 20 per cent. of those set. In the honours stage the proportion varies from 20 per cent. to 40 per cent., there being usually two or three questions in a total of seven or eight, six being the maximum number to be attempted. Nor have the City and Guilds papers a higher ratio, as in the honours steam section of mechancial engineering for one year no heat question was set, and for another year only one in five. This is surely a startingly low proportion for so essentially a thermodynamical subject as steam!

Your correspondent Mr. Bodmer mentions for the encouragement of "Student" that the discussions on steam engine performances at our Institutions is not alone confined to the "professors"; it is perhaps worth while my adding that in the most noteworthy of these discussions of recent years, that on Mr. Willans' well-known experiments, the participants in the discussion and correspondence numbered twenty-six, of whom nine were Professors, the remainder including such all-round men as Dr. Anderson, Mr. Bodmer, and Mr. MacFarlane Gray. But how very small a proportion of practical men, considering that the professors were there almost *en masse!* I remember being much struck some time ago at the earnest attention given by the very practical audience of a Naval Architects' meeting to Professor Cotterill when speaking, and not very popularly, on some thermodynamic question. Shall I be pardoned if I say I think this sort of thing is due to the fact that practical men look to reap where they have not sown! "Student" will, I hope, see even in this another affirmative answer to his question.

Yours, &c.,
Sidney H. Wells.

MR. KAPP'S CANTOR LECTURES.

To the Editor of "Industries."

Sir,—Herewith I beg to hand you copies of correspondence between Mr. Gisbert Kapp and myself relative to particulars given by him concerning our Barking installation.

As the report of this lecture appeared in your last week's issue, I should be greatly obliged if you will kindly find space in your columns for the publication of the enclosed in your issue of this week.

Yours, &c.,
The General Electric Power and Traction Company, Limited.
W. G. M. Mackenzie,
Secretary.

New Broad Street House, 35, New Broad Street,
London, E.C., 25th February, 1891.

[Copies of Correspondence].

Gisbert Kapp, Esq.

Re Cantor Lecture on Monday, 16th inst.

Dear Sir,—I am requested by the managing director to draw your attention to the enclosed printed matter with reference to date relating to the Barking Road Electric Installation, which is the property of the General Electric Power and Traction Company, Limited. The figures thus given are entirely misleading, and the publication of them is calculated to seriously injure our interests, as well as those of the North Metropolitan Tramways Company, and we must request you accordingly to withdraw the Tables IV. and V., and the statements made by you based thereon at the next Cantor lecture, in such a public manner as will be likely to reach all persons before whom the original tables and statements have come.

If the statements have been based upon information obtained from Mr. Frazer, we may call attention to the fact that he left the company's employ in July last, and has since had no opportunity of acquiring any knowledge as to the improvements that have taken place since then, which renders the data published by you still further misleading.

In the event of your failing to comply with our request, we shall, in the interests of our shareholders, be compelled to consult our solicitors on the subject.

Yours faithfully,
(Signed) W. G. M. Mackenzie,
Secretary.

31, Parliament Street, S.W.,
February 21st, 1891.

The General Electric Power and Traction Company, Limited,
35, New Broad Street, E.C.

Dear Sirs,—In reply to your letter of yesterday, the statements to which you object were based on figures obtained from Mr. Frazer, and were given at the Society of Arts distinctly on his authority, and not on mine. After your explanation, which puts a totally new complexion upon the matter, I am of course myself desirous to withdraw from my lecture any statement or table the accuracy of which is questioned, and I shall on Monday withdraw the two Tables IV. and V., and statements connected with them. At the same time, allow me to point out that in your interests, as well as in mine, withdrawal alone would not be so effective as withdrawal combined with the substitution of the correct figures, and I should feel obliged if on Monday you would send me a telegram authorising me to state that when the lectures appear in print the obsolete figures of Mr. Frazer will be replaced by figures corrected up to date and supplied by you.

Yours faithfully,
(Signed) Gisbert Kapp.

THE PRESENT POSITION OF THE ALKALI TRADE.

To the Editor of "Industries."

Sir,—In your fairly moderate article on "The Present Position of the Alkali Trade" in your issue of the 13th inst. (which has only to-day come under my notice) you say, "In our recent review we pointed out that the Union could only succeed in one way, and that was by completely revolutionising its means of production—in fact, by gradually transforming its old plant, and remodelling its manufactures on lines of modern progress."

I cannot at the moment put my hand on the review you refer to, but as one indirectly interested in the newly-formed United Alkali Company, will you kindly allow me to ask just what is meant by "transforming its old plant and remodelling its manufactures on lines of modern progress"? If I understand matters aright, the *raison d'être* of the United Alkali Company, and of the Leblanc group of processes which they work, is principally the manufacture of caustic soda, bleaching powder, chlorate of potash, and (to a less extent) sulphur. If the plant and processes employed for the production of these by the above company are "old," will you kindly indicate which is the new plant and process that has superseded them? Where, and by whom, has this plant and process been worked on a manufacturing scale, and for how many years? What is the present annual production of the four chemicals named by the new process which has superseded the old plant of the United Alkali Company?

I do not speak of *proposed* processes, nor of processes that have not been commercially developed, for if capitalists shrink from every venture excepting such as cannot possibly be prejudicially affected by possible new inventions or future developments, where shall they turn? Not to iron or steel, for we all know that these are soon to be superseded by "the metal of the future," aluminium, the raw material for which is to be found in every clay hole. Not in gas, for the advent of electric lighting sounded its doom a dozen years ago (yet somehow the companies continue to pay their old-fashioned dividends). Not in brewing, for the reformation in the drinking habits of the people (Mr. Goschen's last Budget speech to the contrary notwithstanding) is soon to convert this into a "lost art." Not even in railways or shipping, because both modes of locomotion will ere long be as antiquated as the stage coach or last week's newspaper, consequent on the development of flying machines driven by electricity, generated by thermopiles; said machines necessitating no expenditure for construction or maintenance of permanent way. Who shall say that all these are merely dreams? Who shall say whether any—and if so which—of the 20,000 new inventions every year patented in this country alone will prove more than a dream?

But to return to the question of new inventions in connection with the alkali trade, may we not look at the matter in this light: The chemical elements and compounds have each been endowed with a number of properties most of which are known. But some few may be unknown. Now, unless the unknown properties of certain elements and compounds differ considerably from the known ones (and no amount of experimenting will give them the necessary properties if they do not already possess them), what ground is there for believing that the principal products of the United Alkali Company will not continue to be made by the present processes or by some simple modification of them? To say that these elements and compounds are *not* endowed with the necessary properties would, perhaps, be rash; would it not be equally rash to assert that they *are* so endowed?

To sum up: Are we not justified in drawing the moral: That if the Leblanc alkali maker has anything to fear from the progress of new invention, has he not, at least, equal cause for hope?

Yours, &c.,
Newcastle, 25th February, 1891. M.

[The several interrogatories proposed to us by our correspondent at the commencement of his letter are, we think, answered in a general way by the quotation in our article from the Alkali Inspector's Report. This gentleman states that "the struggle between the older and newer processes is no longer doubtful." The words "newer processes" will, we take it, be quite clear to the mind of our correspondent. The review referred to in our article is one relating to the chemical progress of the past year, and will be found on page 43 of our issue of the 9th ult.—Ed. *Industries.*]

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—Your correspondent "D. H. N." mentions one of the strongest arguments that could be advanced in support of the pipe line gas scheme. Although the Weights and Measures Act of 1889 gave discretionary powers for the London County Council to take action against coal merchants for giving under measure, nevertheless, the poorer classes are robbed in a wholesale and shameless manner, and, as evidence of the extent of this fraudulent dealing, the officers who have the work of detection brought up sufficient evidence during some seven or eight months of last year to secure nearly 400 convictions. If the London County Council would boldly take in hand the scheme of heating-gas supply suggested, they would confer more real benefit on London and its citizens than has been effected by all the legislative enactments since the middle of the sixteenth century.

Yours, &c.,
George M. Collins.

154, Canning Street, Liverpool,
23rd February, 1891.

To the Editor of "Industries."

Sir,—While it is impossible to be wanting in sympathy with the object of Mr. Thwaite's scheme, it seems to me that most people will regard his proposal to gasify fuel far away—one hundred and fifty miles or so in the provinces—and pipe it to London as too heroic, involving as it does, upon Mr. Thwaite's own showing, an outlay of at least ten millions sterling; attacking one of the most powerful gas corporations in the world; and taking from railway companies, carters, and middlemen, such an important source of income that their opposition is certain. Mr. Thwaite has not told us what is to be the price of the gas per 1,000ft. to the consumer, and what he considers a fairly probable dividend to the syndicate at that price. Moreover, it would be some satisfaction to many, who, like myself, have read with interest Mr. Thwaite's very admirable exposition of his scheme, to know whether he purposes putting all his eggs in one basket—*i.e.*, depending on one pipe from each coal or gasification centre—and what would be the result of a hitch or breakdown. As far as I can see, the pipe lines must be, if single, 9ft. in diameter.

Much of the public support will depend upon the selling price of the gas. Here, in Manchester, a memorial has been presented to the Corporation Gas Committee to induce them to reduce the price of gas to 2s. per 1,000 cubic feet, with a view to encouraging its use for heating purposes. My own impression is that gas

Digitized by Google

must be supplied at even less than this before the public will take kindly to its use as fuel. To be successful there are two other points to be attended to. I believe I have seen the most modern forms of gas-heating stoves, and I have taken great interest in the use of gas as a heating agent for twenty years, watching each development, but to-day I do not know of a gas-heating stove whose radiating power is comparable to a very small coal fire; secondly, I do not know of any gas stove which does not discharge its products of combustion into the air of the room but what has the objectionable feature that it parts with those products by discharging them at far too high a temperature into the chimney, this being a great loss of heat. Your correspondent, "B. B." (page 136), seems to know of a stove which by an arrangement of flues is free from this objection. I, for one, should be glad to know what the arrangement is like.

Mr. Thwaite has displayed characteristic boldness by proposing to pipe the gas to London, but Dr. Bailey has shown what I think is the best way to begin—namely, to try the experiment on Manchester (and Liverpool). The Lancashire coalfield is close at home, and from a successful experiment of this magnitude the public confidence in the larger London project would be assured. *Manchester has fogs at least as bad as any London fog.*

The suggestion of your correspondent, James Armer (page 136), that the coal should be gasified at London would overcome many difficulties. Of course, it is a distinct departure from Mr. Thwaite's scheme, as it eliminates the prominent feature of piping gas a hundred and fifty miles, but the railway interests and the carting interests would be met. Wherever the gasification of the fuel is effected, one point must be insisted upon, that the purification plant for recovering sulphur, ammonia, and hydrocarbons shall be in duplicate, and each of such a size as to efficiently remove all these impurities from the gas; and by duplication the breakdowns which we often hear of at ordinary gas works would not—as now—be followed by the admission of impure gas into the mains, a most important consideration.

After all, in these days when a chemical union of eight millions or so of capital can be financed, it does not seem outside the range of probability that, by the co-operation of existing gas concerns with practical reformers like Mr. Thwaite, a scheme involving ten or even twenty millions of capital could be successfully launched and steered.

Yours, &c.,
W. Jesse Lovett.

154, Eccles New Road, Salford, 24th February, 1891.

THE SKILLED LABOUR MARKET.

The reports sent in to the Board of Trade by twenty-one societies, representing 239,080 members, show that of this number 8,063 men were unemployed during January as compared with 7,253 men in December, an increase of 810. The proportion of men unemployed has thus increased from 3·05 per cent. to 3·37 per cent. This increase may be attributed to the prevalence of recent strikes, of which the number increased from 60 in the previous month to 73. There were 25 strikes in the cotton trade, 10 strikes in the coal trade, and 7 strikes among dock labourers. The effects of the Scottish railway strike have severely affected the men engaged in the iron trade, and the proportion of unemployed increased from 5 to 16·25 per cent. The deficiency of raw material was the cause of this increase, and it seems probable that trade will now return to its normal condition. The severe weather seriously affected the building trades, and its effects were still felt at the end of last month. In the engineering branch of the iron trade the proportion of unemployed in the chief society, which numbers about 70,000 men, had decreased from 2·7 to 1·9 per cent. The shipbuilding trade also is in a very fair condition.

THE CLEVELAND INSTITUTION OF ENGINEERS.

At a meeting of this Institution, held on the 23rd inst., at Middlesbrough, the President (Mr. Charles J. Bagley) being in the chair, Mr. Wm. Hawdon read a paper entitled "Notes on American Blast-furnace Practice, and a Comparison with the Work Done in the Cleveland District." Mr. Hawdon said that in the Northern States they had in the best works a splendid plant, with all the latest improvements that European practice and their own experience of some years' working had given them, together with rich ores containing about 63 per cent. of iron and good fuel. In the Southern States the furnace plant was of a cheaper and less substantial construction. In manufacturing pig iron they endeavoured to keep before them two chief points—viz., economy of fuel and output of production. The American practice was to build a separate blast-main for each furnace, with two or more blowing engines coupled to it, and, by an arrangement of valves, each engine could be blown into any particular main. There was then fixed a certain "make" to be arrived at which required a certain pressure of blast and a certain number of revolutions of the engines per minute. They ran their engines at this speed, having an indicator on each engine, showing at a glance the number of revolutions per minute. Each engine had a governor attached, and this was necessary to maintain the equal speed required, for when the furnace began to "hang" a little, or not drive so freely, the resistance to the blast was greater. The Americans attached very great importance to this arrangement, and it seemed almost incredible how Cleveland engineers could have allowed this valuable arrangement to escape their notice. Several furnaces in America were making from 2,300 to 2,400 tons per week, but the general make was about 1,700 tons. The author claimed that the practice in Cleveland was, on the whole, the best, and much superior in some respects to the American. In fact, large makes in America were at the expense of a lack of economy in fuel; stronger and more costly engines were required, with more strain on the men.

In the discussion which followed, the President thought there was room for improvement in the ironworks of the north of England, and that the great improvements which were going on at Jarrow and other places would become general.

THE CHAMBER OF SHIPPING.

On the 20th inst. the annual meeting of the Chamber of Shipping was held, Mr. T. L. Devitt, the President, being in the chair. There was a large attendance of those interested in shipping, including representatives from the affiliated societies. The report of the Council showed that two societies, the Britannia Insurance Association and the Sunderland Shipowners' Society, had been affiliated to the Chamber during the past year, the number of affiliated societies now being twenty-five. The President said that the Chamber had taken an important step in instituting the Federation of Shipowners. The societies throughout the kingdom had rendered every assistance, and on the previous day the Chamber had been strengthened by the addition of 750,000 tons from Liverpool. Although the manifesto of the Federated Trades Council had been withdrawn, the men were still prevented from working on the boycotted ships. He hoped that the members of the Shipping Federation and the Council would always work together to resist the onslaught which was being made against them. Sir William Gray, the President for the ensuing year, said that the causes of the present depression in the shipping industry were the over-supply of tonnage and the high price of fuel and labour. A discussion afterwards took place as to the advisability of forming labour conciliation boards, and Sir A. Rollit, M.P., referred to the successful working of the London Conciliation Board. The resolution in support of the proposal was eventually withdrawn. At a dinner in the evening, Sir D. Currie, M.P., referred to the competition of Germany, France, and the United States, which was favoured by the subsidy laws of those countries. It was necessary that there should be a strong mercantile marine, in order that the food supplies of the country might not be interfered with in the event of war.

TRIAL OF H.M.S. "PALLAS."

A welcome reaction appears to have set in as regards the trials of Her Majesty's ships, as, in addition to the very successful results obtained in the "Gossamer," "Latona," and, still more recently, in the "Pearl," at Pembroke, we have to add an equally good result obtained at Portsmouth on the 20th inst. with the "Pallas."

The "Pallas" is a third-class cruiser of what was known as the "Pandora" class, taking the "Pandora," now "Katoomba," as the typical ship, and she is thus exactly similar to the six Australian cruisers. These were, when laid down, called second-class, but since the increased dimensions given to such second-class cruisers as the "Latona," &c., they have been relegated to the third class. The indicated horse-power with forced draught is 7,500, and speed 19 knots. With natural draught 4,500 indicated horse-power for eight hours consecutively are required, which should give a speed of about 17 knots. The trial on Friday last was by natural draught so called—more strictly draught assisted by not more than ·5in. air pressure due to the fans—and the required results were most easily obtained. To all intents the trial was one of natural draught, for, though the stokeholds were closed and the fans working, yet the air-pressure rarely rose above ·1in., and directly it began to do so the steam pressure rose rapidly and the fans had to be checked. With the very feeble assistance thus obtained from the fans the indicated horse-power was for the consecutive hours—4,867, 5,017, 5,199, 5,141, 4,974, 5,068, 5,062, and 5,115, or a mean of 5,055 for the eight hours, being 555 in excess of that stipulated for. The mean speed of four runs on the measured mile was 17·566 knots, so that we may safely say that with open stokeholds the "Pallas" will be a 17 knot boat.

The machinery worked very easily, and very little water was required on the bearings, but this, of course, might be expected. The crucial test will come in on the full power trial, which is fixed for to-day. With regard to this question of bearings, there are few things which strike the eye more, in connection with modern marine machinery, than the completeness of the lubricating arrangements, as compared with those of a few years back. Now we have one oil tank, from which runs a main service pipe, supplying the branches to every part, each of which has its regulating valve and its rate of supply almost invariably visible to the eye, so that the engineer officer on watch has the control of the whole arrangement right under his hand.

As already stated, the boilers did easily all that was expected of them, and, as it has been in nearly every case of failure the boilers which have given out, some instruction may be gained by a consideration of the differences, if any, between the boilers of the "Pallas" and, say, the "Katoomba," which has not been quite such a success, although almost identical in design, and built and engined by the same makers, Messrs. Hawthorn, Leslie, & Co. Forced draught was introduced in the Royal Navy so as to obtain a large horse-power from a small weight of boiler, by increasing the quantity of coal burnt per square foot of grate; but the proportions of the boiler, as regards ratio of tube surface and heating surface to grate surface, remained about as they were for natural draught. But one alteration in design was proposed and carried out in, among others, the "Galatea" and "Undaunted," with the same idea in view of saving weight—viz., the use of double-ended boilers having only one combustion chamber common to the whole of the furnaces. Comparing a double-ended boiler of this class with two single-ended ones put back to back, the weight of the two backs of the boilers and of the backs of the combustion chambers is saved. This answered very well in the two ships named, the "Galatea," with 496 square feet of grate surface, developing 9,000 i.h.p., or about 18·5 per square foot of grate. This success led to the more extensive use of this class of boiler, and it was expected with increased air pressure to obtain 20 i.h.p. per square foot. Then, however, began to come a series of unfavourable results, and among them the accident to the "Barracouta," in which the back draught—how caused has not yet, and probably never will be, satisfactorily explained—burnt the unfortunate occupants of the stokehold. It was thought that the common combustion chamber may have had some connection with the accident, and so it was divided off by brick partitions into separate chambers, and the boilers of other ships, including the "Katoomba," were divided in the same way, so that with four furnaces she has four combustion chambers, not separated, however, by steel plates and water spaces, but by brick walls. The "Pallas," on the other hand, although originally intended to have the one common chamber, now has four distinct combustion chambers, separated by water spaces, thus being similar to the "Latona" class, except that, the total length of boiler not having been altered, her combustion chambers are necessarily very shallow.

In spite of the brick partitions, an accident occurred on the trial of the "Katoomba" exactly similar to that on the "Barracouta," flames issuing into the stokeholds and burning the stokers. To complete the similarity, no satisfactory explanation has been given; the tubes showed signs of leaking, but whether the leaks caused the back draught or *vice versâ*, or whether some other cause produced both, is not clear. Apart, however, from the accident, it is clear that, as between the common combustion chamber in the state it has now arrived at with its brick partitions, and the separate combustion chamber to each furnace, there can be little doubt as to which is in every way the best. The gain in weight is gone, because the bricks are at least as heavy as the steel sides, and with that goes all the advantage, because in all other respects the separate system is the best. Of course, the weight of the backs was saved, but then nearly the most efficient part of the chamber was taken away, for the hot gases coming direct from the furnace strike the back and meet it under the most favourable conditions for giving up their heat, and this heat has then only to travel through a thin plate to reach the water; on the other hand, the tube plate is thicker, the gases do not strike it so directly, and it is cut up by the tubes. Theoretically we should expect the "Pallas" to do better than the "Katoomba," and practically this is confirmed, for what the "Pallas" did with ·1in. of air it was necessary to use ·75in. for in the "Katoomba." This means that more heat was generated in the furnace of the latter, but, instead of passing into the water, the excess simply went up the funnel. Taking all things together, it appears probable that we have seen the last of the combustion chamber common to all the furnaces.

The "Pallas" vibrated considerably during the trial, the revolutions, which averaged 144·5, nearly agreeing with her natural period; it is probable that there will thus be less vibration at the higher power.

TRANSFORMER DISTRIBUTION.*

(*Continued from page* 177.)

Let us now assume the self-induction to be 0·05. The resulting diagram is shown in Fig. 2. The double-load current is almost exactly 40 amperes. Various other examples may be taken

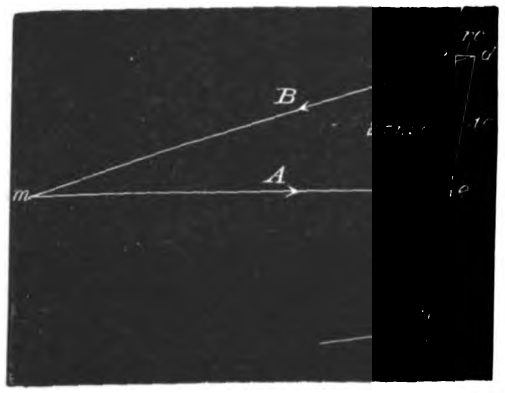

Fig. 2.

in the same way. We thus find that according to the self-induction hypothesis the difficulty does not lie, as commonly supposed, in getting enough self-induction in the armature; the trouble is that there is generally too much. But in machines from 25,000 to 50,000 watts it is exceedingly difficult to make dynamos that will not run perfectly in parallel, so great is the permissible margin of self-induction.

The orthodox hypothesis thus tells us that with ordinary sizes of machines it is exceedingly difficult to design them so that they will not run in parallel. Either, therefore, all ordinary machines run perfectly in parallel, or the orthodox hypothesis is wrong.

Parallel Running according to the Armature Reaction Theory.

Take the case of a machine like the Siemens, with coils passing between poles. If there is a continuous current in the armature, in some positions it will assist the field magnets, and in others it will to some extent weaken them, while in intermediate positions it has no effect on the magnets as a whole. In an alternate-current machine, though the armature current is alternating, relatively to the field magnets it is direct. If a series of

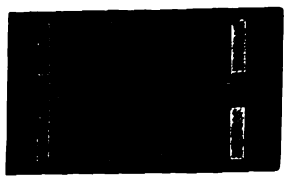

Fig. 3.

instantaneous photographs of the armature current could be taken, each part of the air space would have its direct current.

If the pressure curve of a machine were traced, and placed in the diagram of the poles, it would be as shown in Fig. 4. The positive direction of the current or pressure in the armature and field-magnet coils is shown by shading, the negative by dotting. If electricity flows in the armature when the sides of the coils are in the active fields, one side of the field between the poles is

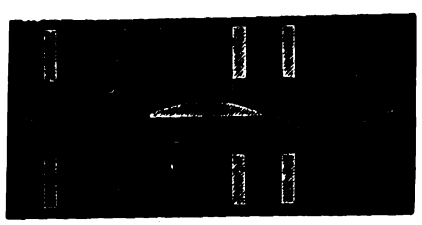

Fig. 4.

strengthened and the other weakened, as shown in Fig. 3. The field thus becomes stronger on one side. The curve of pressure thus gets displaced, as shown in Fig. 5.

It will be seen that each magnet is now exposed to the back induction due to the armature current. A circuit *a* taken round

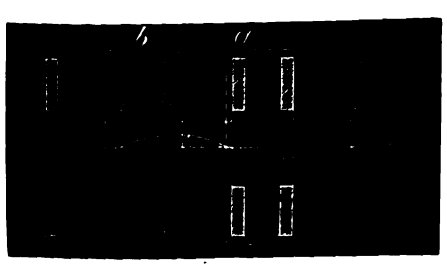

Fig. 5.

the field-magnet circuit is interlinked with the whole wave. The line integral is not changed if it is taken round any other circuit, so that the sides are the same distance apart as they are in *a*. A circuit taken as shown at *b*, however, includes only half a wave,

* Abstract of a paper read by Mr. J. Swinburne before the Institution of Electrical Engineers on the 19th inst.

so that from Fig. 5 both the cross and the back induction could be completely worked out.

The effect of the armature current, then, is first to make the current lag relatively to the position of the field magnets, and then to lessen the pressure as a whole. It thus resembles the effect of the insertion of artificial self-induction.

A machine without friction may be imagined, and when its field magnets are separately excited, so as to give an electromotive force exactly equal to that of the mains when it is connected so as to be in step, it runs as a motor taking no current. At each instant the electromotive force of the machine is exactly equal to the electromotive force of the mains, so no current passes. On putting on some load the machine begins to lag. As soon as the machine lags, a current passes through the armature. The current due to the difference of two equal alternating electromotive forces is not in step with either of them. This is shown in Fig. 6, where two pressure curves are

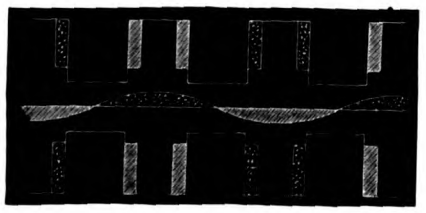

Fig. 6.

drawn a little out of step. The current through resistance is proportional to the shaded parts. If the electromotive force of the machine were still the same as that of the mains, it would still develop no power as a motor, because at some parts of the period it would be supplying power to the mains, and at other parts the mains would be supplying power to the armature; for at any instant the armature current would be equal to the difference of the two electromotive forces divided by the resistance of the armature. The average current curve is shown in Fig. 7. The electromotive force of the machine does not, however, remain equal to the main electromotive force, merely differing from it in phase, but is decreased by the reaction of the armature current on the field magnets. The average current

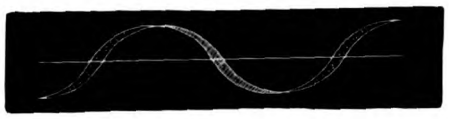

Fig. 7.

curve shows that there would be considerable back induction, or many ampere-turns tending to weaken the field. This weakening of the field by the armature reaction allows the main also to supply a current against the electromotive force of the machine, so that it acts as a motor, and power can be taken from it.

If the machine is to be worked as a generator in parallel with the main circuit—that is to say, if it is to supply power to the mains instead of to take it from them—the same reasoning holds good. If the engine supplies just a little too much power, the machine will begin to lead, and an armature current will pass, which will strengthen the fields by reaction, and the machine will at some instants act as a generator, because its electromotive force is now a little higher, as the armature current has strengthened its field. Similarly, if the steam of the engine were completely shut off, the machine would lag until it worked as a motor.

According to the armature reaction theory, then, whether a machine will run in parallel with others depends on its armature resistance and armature reactions. It must be borne in mind that most machines have cast-iron fields, which may not respond to the armature reactions quickly, so it may be difficult or impossible to run them in parallel.

Another important consideration is the government of the engines. The whole question of the government of central stations requires the most careful consideration. I have dealt with the matter at some length elsewhere (*Industries*, September, 1890), but the subject should be very fully thought out in designing stations.

Arrangement of Station.

If the machines are employed in parallel, they may feed into common bars, as in the case of direct currents. If each district must have its own circuit—which seems to be generally assumed necessary—each circuit may be led away from the common bars with a transformer regulator in it. It is a great advantage to transform up, and to have all the switches, connections, and measuring instruments on the low-pressure side. The high-pressure circuits may then be arranged to have no metal exposed anywhere. If each district must have its separate circuit, it has its own step-up transformer, with its regulator.

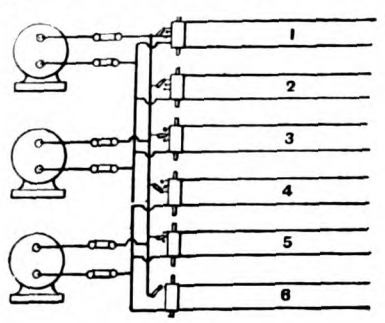

Fig. 8.

One arrangement is shown in Fig. 8. The dynamos are all in parallel, and wound for 100 volts, the immediate neighbourhood of the station being fed direct. Each feeder circuit has a transformer with a variable number of primary turns. A compensated voltmeter is placed on each, and all the attendant has to do is to alter the switches a little occasionally, so as to keep all the instruments' pointers vertical.

(*To be continued.*)

THE ELECTRIC TRANSMISSION OF POWER.*

The lecturer, in commencing his second lecture, said he wished to withdraw Tables II. and VI. (given in our last issue) for the present, while some alterations were being made in them. Oersted's and Faraday's electromagnetic discoveries were described, and it was experimentally shown how electrical energy may be transmitted between two dynamo machines. The fields of both machines were separately excited, and the two armatures coupled in series with one another; and on turning one armature by hand, the second armature was seen to rotate also. An electromotor will run at such a speed that the counter e.m.f.—that is, the e.m.f. induced in its armature by the rotation—is almost, but not quite, equal to the e.m.f. supplied to its brushes, the difference between the two e.m.f.'s being such as to allow the current required by the motor to pass through the armature resistance. The electrical power which a motor converts into mechanical power is equal to the product of the counter e.m.f. set up in its armature multiplied by the current passing through the armature.

In the electric transmission of large powers over considerable distances, it is always advisable to use high voltages, since the higher the voltage the less is the weight of copper required in the supply mains for a given percentage loss over their resistance. In each case that arises, there is a particular voltage at which it is most economical to work. For the transmission of large powers, multipolar generators and motors are generally used, as they have several advantages over the two-pole machines, the chief being that, for a given large output, a multipolar is cheaper and weighs less than a two-pole, and also its armature reaction is less. There is a limit to the output of a two-pole machine, and this limit is about 100 horse-power. Beyond this the armature reaction is too great for satisfactory working, and a multipolar should be used. The armature conductors of a multipolar machine may be connected in parallel, in series, or in combinations of parallel and series. Table III. gives the connections for an eight-pole series wound-drum armature. The reader is supposed to be looking at one end of the armature, and the letters D and U indicate "down" conductors and "up" conductors, and the letters F and B front cross-connection and back cross-connection respectively. Thus the winding at the beginning is down bar 202, across back connection; up bar 25, across front connection; down bar 50, across back connection, and so on.

The regulation of the speed and power of a motor is a very important subject. Experiments were made with a shunt motor to show that if the field magnetisation of the motor was weakened by inserting resistance in the shunt the speed increased, and if the field magnetisation was increased the speed decreased, the voltage at the motor brushes being kept constant; also to show that the speed varied directly with the e.m.f. supplied to the brushes if the field magnetisation was kept constant. The same shunt motor was connected by a belt to a dynamo, and this dynamo was arranged to feed an arc lamp, and it was experimentally shown that the motor actually ran faster when the lamp was burning than when it was switched off, the motor being supplied at constant potential. When the current through its armature was increased the increase of loss in the field magnetisation due to the armature reaction was greater than the increase of loss of potential over the armature resistance, and therefore, to get up the proper counter e.m.f., the motor ran faster. Is is evident that if the armature reaction had exactly counterbalanced the loss over the armature the speed would have remained absolutely constant. In machines which have not sufficient armature reaction a demagnetising series coil should be wound on the magnets.

A shunt motor having wrought-iron magnets will run at a constant speed if it is worked much below its normal voltage and current, and supplied with a varying voltage. This is because the machine is worked on the straight part of its magnetisation curve, where the lines of force through the armature are proportional to the exciting ampere turns. The chief disadvantage of a shunt motor is that in order to prevent the armature being burnt up a resistance is required in the armature circuit on starting; this resistance may be short circuited as soon as the motor has started, and its insertion

THE ELECTRIC TRANSMISSION OF POWER.

TABLE I.

$$\text{Volts} \ldots\ldots = Hvl\,10^{-8}$$
$$\text{Kilogrammes} \ldots\ldots = \frac{Hcl}{9{,}810{,}000}$$

C Total current through armature; c, current through single armature conductor.
e_a E.M.F. in armature in volts.
τ Number of active conductors counted all round armature.
p Number of pairs of poles ($p = 1$ in a two-pole machine).
n Speed in revolutions per minute.
F Total induction in C.G.S. lines.
Z ,, English lines.

Electromotive force:
$e_a = F\tau\frac{n}{60}10^{-8}$, $e_a = Z\tau n\,10^{-6}$ — for two-pole machines.
$e_a = pF\tau\frac{n}{60}10^{-8}$, $e_a = pZ\tau n\,10^{-6}$ — for multipolar machines with series wound armature.

Torque.....
Kilogramme-metres $= 1{\cdot}615\,F\tau C\,10^{-10}$; Foot-pounds $= 7{\cdot}05\,Z\tau C\,10^{-6}$ — for two-pole machines.
Kilogramme-metres $= 3{\cdot}23\,F\tau cp\,10^{-10}$; Foot-pounds $= 14{\cdot}10\,Z\tau cp\,10^{-6}$ — for multipolar machines.

TABLE II.

MOST ECONOMICAL CURRENT FOR ELECTRIC POWER TRANSMISSION.

D	Distance in miles.
a	Section of conductor in square inches.
E	Terminal volts at generator.
e	Terminal volts at motor.
HP_g	Brake horse-power required to drive generator.
HP_m	Brake horse-power obtained from motor.
c	Current in amperes.
	Efficiency of generator, 90 per cent.; efficiency of motor, 90 per cent.
g	Cost in £ per electrical horse-power output of generator.
m	Cost in £ per brake horse-power output of motor, including regulating gear.
$G = 9g\,HP_g$ ...	Cost in £ of generator.
$M = m\,HP_m$ ...	Cost in £ of motor and regulating gear.
$t = 18{\cdot}2\,Da$ ...	Weight in tons of copper in line.
K	Cost in £ per ton of copper, including labour in erection.
s	Cost in £ of supports of line per mile run.
p	Cost in £ of one annual brake horse-power absorbed by generator.
q	Percentage for interest and depreciation on the whole plant.

$$\text{Capital outlay} = g\frac{Ec}{746} + m\,HP_m + Ds + \frac{1{\cdot}6\,K\,D^2c^2}{Ec - 880\,HP_m} = A.$$

$$\text{Annual cost per brake horse-power delivered} = q\frac{A}{HP_m} + p\frac{HP_g}{HP_m}.$$

Put $B = \frac{Ep}{670} + q\frac{Eg}{746}$.

$j = \frac{880}{E}HP_m$, the current which would be required if the line had no resistance,

and $\beta = j^2\frac{EB}{1{\cdot}6\,q\,K\,D^2 + EB}$; then the most economical current at the given voltage E is—

$$c = j\left\{1 + \sqrt{1 - \frac{\beta}{j^2}}\right\}$$
$$c = j\left\{1 + \sqrt{\frac{1{\cdot}6\,q\,K\,D^2}{1{\cdot}6\,q\,K\,D^2 + BE}}\right\}$$

For very long distances the term under the square root approaches unity and the most economical current the value $2j$; from which it follows that under no circumstances will it be economical to lose more than half the total power in the line.

TABLE III.

* This includes regulating apparatus, instruments, posts, insulators, lightning arresters, erection, and supervision.

and removal may be automatically effected by a switch moved by a centrifugal governor on the motor shaft.

For large isolated electrical transmissions, where the generator is run at constant speed, and the motor is required to keep constant speed, both generator and motor are usually series wound, and so designed that the difference between their characteristics (curve connecting internal e.m.f. and current for constant speed) for any current is equal to the loss of volts over the complete electrical circuit when that current flows through it. When this is done the generator and motor automatically vary the e.m.f. and current, and the motor runs at constant speed. In electrical tramcars, where a large torque is required at starting, series motors are generally used; the field coil connections are led to switches on the conductor's platform, so that the coils may be connected in series or parallel as required.

On account of the lateness of the hour Tables II. and IV. were not dealt with at length.

THE ELMORE COPPER PROCESS.

As promised in our issue of the 30th ult., we now give some particulars of the works of the Elmore's Patent Copper Depositing Company, Limited, which are situated at Haigh Park, Hunslet, near Leeds. The works are close to the Midland Railway, with which a siding communicates, and also within easy reach of the local canal.

Strickly speaking, there will be two distinct companies, with their buildings on adjacent sites—one for making tubes, and the other wire. At present the wire company's works consist of a brick building in course of construction, and our recent visit was confined to the more nearly completed works of the company engaged in the manufacture of tubes. An idea of the general aspect of the place will be gathered from the accompanying illustrations, Figs. 1 and 2.

Starting with the raw material, in the form of Chili bars, containing on an average 97 per cent. of copper and 3oz. of silver and ½oz. of gold per ton, the first operation is to reduce the metal to a form suitable for use in the subsequent process. To this end it is melted in ordinary furnaces, run into a ladle, the slag skimmed off, and the copper granulated by pouring it into a tank of water. During this operation the sharp difference in properties of the metal and its oxide (of which the slag mainly consists) is well brought out by their behaviour on sudden cooling: the metal is at once quenched by reason of its high conductivity, and causes little commotion during its solidification; the drops of slag, however, are solidified on the outside while retaining a hot core, and, in consequence, spit vigorously. The granulated copper is of even size and irregular shape, exposing a considerable surface, which properties fit it well for its office as anode in the depositing tanks. This is the only fusion to which the metal has to be subjected.

From the melting shed the granulated copper is conveyed to the tank room, but before tracing its career further we must devote a little space to a description of the boilers, engines, and dynamos. There are two boilers, each of 250 h.p., supplying steam to three Willans & Robinson engines, two driving dynamos by Mather & Platt and one driving a dynamo direct. An Elwell-Parker dynamo stands idle at present, and a horizontal Fowler engine is about to be put in. When the installation is complete, the power available will be capable of depositing 25 tons of copper per week. At present one Willans engine and its dynamo are running, supplying current for such tanks as are in use, but a new shed is just completed, and is only waiting for the tanks; it will then represent 10 out of the 25 tons output.

Passing to the tank room that is in actual use, the process of depositing is seen. The granulated copper, of which the preparation has been described above, is laid on a copper tray at the bottom of the tank which serves as the anode. In most, if not all, of the other processes of copper deposition, the anodes have been, or are, composed of plates cast to the size of the tank, and usually hung vertically. Very material disadvantages result from such an arrangement. In the first place, owing to the different densities of the electrolyte and the products of its electrolysis (in this case the difference between the densities of a strong solution of sulphate of copper and of dilute sulphuric acid), the liquid in the neighbourhood of the anode is unlikely to be uniform in composition in successive horizontal strata. In consequence, corrosion of the anode will occur irregularly, according to the greater or less degree of saturation of the liquid in contact with it. This same irregularity will be accentuated by the want of uniformity of the composition of the anode itself; even in refined copper there is a tendency to the localisation of the comparatively small quantities of impurities it contains, and it is inconceivable that a similar but more marked divergence does not obtain in crude copper. The result of these causes is the local attack of the anode leading to portions being detached by the failure of adjacent parts, necessitating renewal long before the whole of the metal is dissolved, and consequent reworking of the scrap. The particular arrangement of granulated copper on a horizontal tray, adopted in the Elmore process, avoids these difficulties. Above the tray serving as the anode is a cast-iron cylinder, revolving on a horizontal axis and constituting the cathode; a solution of sulphate of copper is the electrolyte. The revolving cylinder is completely immersed, and contact is made with it by a copper brush pressing upon its surface near one end. An agate burnisher, applied to the cylinder much as a tool is to work in the lathe, only

Digitized by Google

that it is disposed nearly vertically instead of horizontally, is given a traversing motion by means of a horizontal shaft at the back of the tank which extends the whole length of a set of tanks. This shaft for a length at one of its ends equal to that of a single tank is provided with a screw thread, which, working in a stationary nut, causes the burnisher in each tank to travel from end to end of the revolving cylinder to which it is applied; at the end of the traverse its motion is automatically reversed, and it returns in precisely the same manner. It thus, as it were, cuts a shallow screw upon the newly deposited copper. The rate of traverse is in such relation with the speed of revolution and the width of the burnisher that each "cut" of the burnisher overlaps that which precedes it, leaving no intermediate unburnished spaces. It must not be supposed that there is an actual abrasion of the copper, the motion is that of a screw cutting lathe, and screw-like markings result, but that is all. It is this burnishing process that is claimed to be the cause of the remarkable properties that the deposited metal appears to possess. There is no room for doubt but that it has a very definite effect on the structure of the copper film. We saw at the end of each cylinder which was not exposed to the action of the burnisher, but which was only pressed on by the copper brush making electrical connection with it, a rough pimply deposit of crystalline copper, presenting a sharp contrast to the even surface of the burnished portion.

It is well known that copper of this description is so weak a material that it may be said to be scarcely coherent. This was strikingly shown during our visit by an interesting little experiment. The end of one of the finished cylinders presenting this rough and pimply appearance was struck a very moderate blow with a small hammer, and practically began to break up, the nodules or excrescences of crystalline copper being jerked off quite freely. Of course, it might be urged that this crystalline and incoherent condition might be avoided by reducing the current density, and, where other means are wanting, this method is certainly practicable, and, indeed, moderately efficient; but this argument would leave out of sight the main merit of the Elmore process, which is that a high current density may be used (with the aid of the burnisher) without producing incoherent crystalline copper.

As the rate of deposition is, even with a high current density, slow, the commercial difficulties of a process which voluntarily neglected to avail itself of the utmost attainable would be enormously enhanced, as the capital locked up in the copper while in the act of being deposited would be correspondingly increased. It is stated that the appearance of the surface of the burnished copper is a criterion of the condition of the inner layers, as a roughness or pimple once formed is not eliminated by subsequent deposition and burnishing.

With regard to details of the process carried out in the depositing room, it may be mentioned that the pressure on the burnisher is obtained and regulated by means of an indiarubber band, that the tanks are lined with a special composition of fairly elastic nature to prevent chipping and cracking, and the cast-iron cylinders on which the tubes are made, of course, require special care in manufacture in order that their surface may be sufficiently smooth. The whole execution of the depositing is so nearly automatic that the process goes on day and night with scarcely any attention. A thickness of ⅛in. is generally obtained in about six complete days.

The tube thus formed on its mandrel is taken to the machine shop, where it is rolled off. The method appears curious, but is really very simple and effective. The copper encasing the cast-iron mandrel is pressed upon by three rollers while the whole revolves; the rollers are given a traversing motion from end to end of the mandrel, and produce a dilatation of the copper casing. After undergoing this process the tube slips readily from the mandrel, the waste end where the burnisher has not been is cut off, and it is ready for use.

The production of copper tubes direct from granulated crude copper having thus been demonstrated, the quality of the deposited metal remained to be ascertained. The company state that they are in the habit of controlling the quality of the output by testing a portion cut from every tube made. A register is kept of the results thus obtained, and the history of any piece can be traced at any time.

For breaking the specimens the firm have a 30-ton testing machine by Herriot, of Glasgow, a vertical pattern much resembling the well-known Wicksteed machine, which is sufficient for their ordinary needs. A test was made in our presence of a strip cut from a cylinder in the condition in which it comes from the rolling-off machine—that is to say, unannealed. Its dimensions were 1·564in. by 0·191in., giving an area of 0·299 square inch. It broke at 6·15 tons, corresponding to a tensile strength of 20·6 tons per square inch, and had an elongation of 21 per cent. Seeing that ordinary copper of anything like this strength is so hard that its extension is extremely small, this must be considered a remarkable result. The company are prepared to guarantee the metal they supply to have a tensile strength of 20 tons per square inch, and an extension of at least 15 per cent. It is not found that cutting the strip for testing from the cylinder parallel with its axis instead of circumferentially makes any appreciable difference in the test.

Besides the above numerical instance of the quality of Elmore copper, its behaviour in the workshop calls for some remarks. Ordinary copper when worked is hardened so considerably that repeated annealing is necessary to prevent cracking. It is stated that Elmore copper can be bent or flanged without annealing. Seeing what injury may result from the exposure of copper to the complicated products of the combustion of gaseous or solid fuel, the advantage accruing from this special property goes without saying. But the mechanical properties of

THE ELMORE COMPANY'S TUBE WORKS.

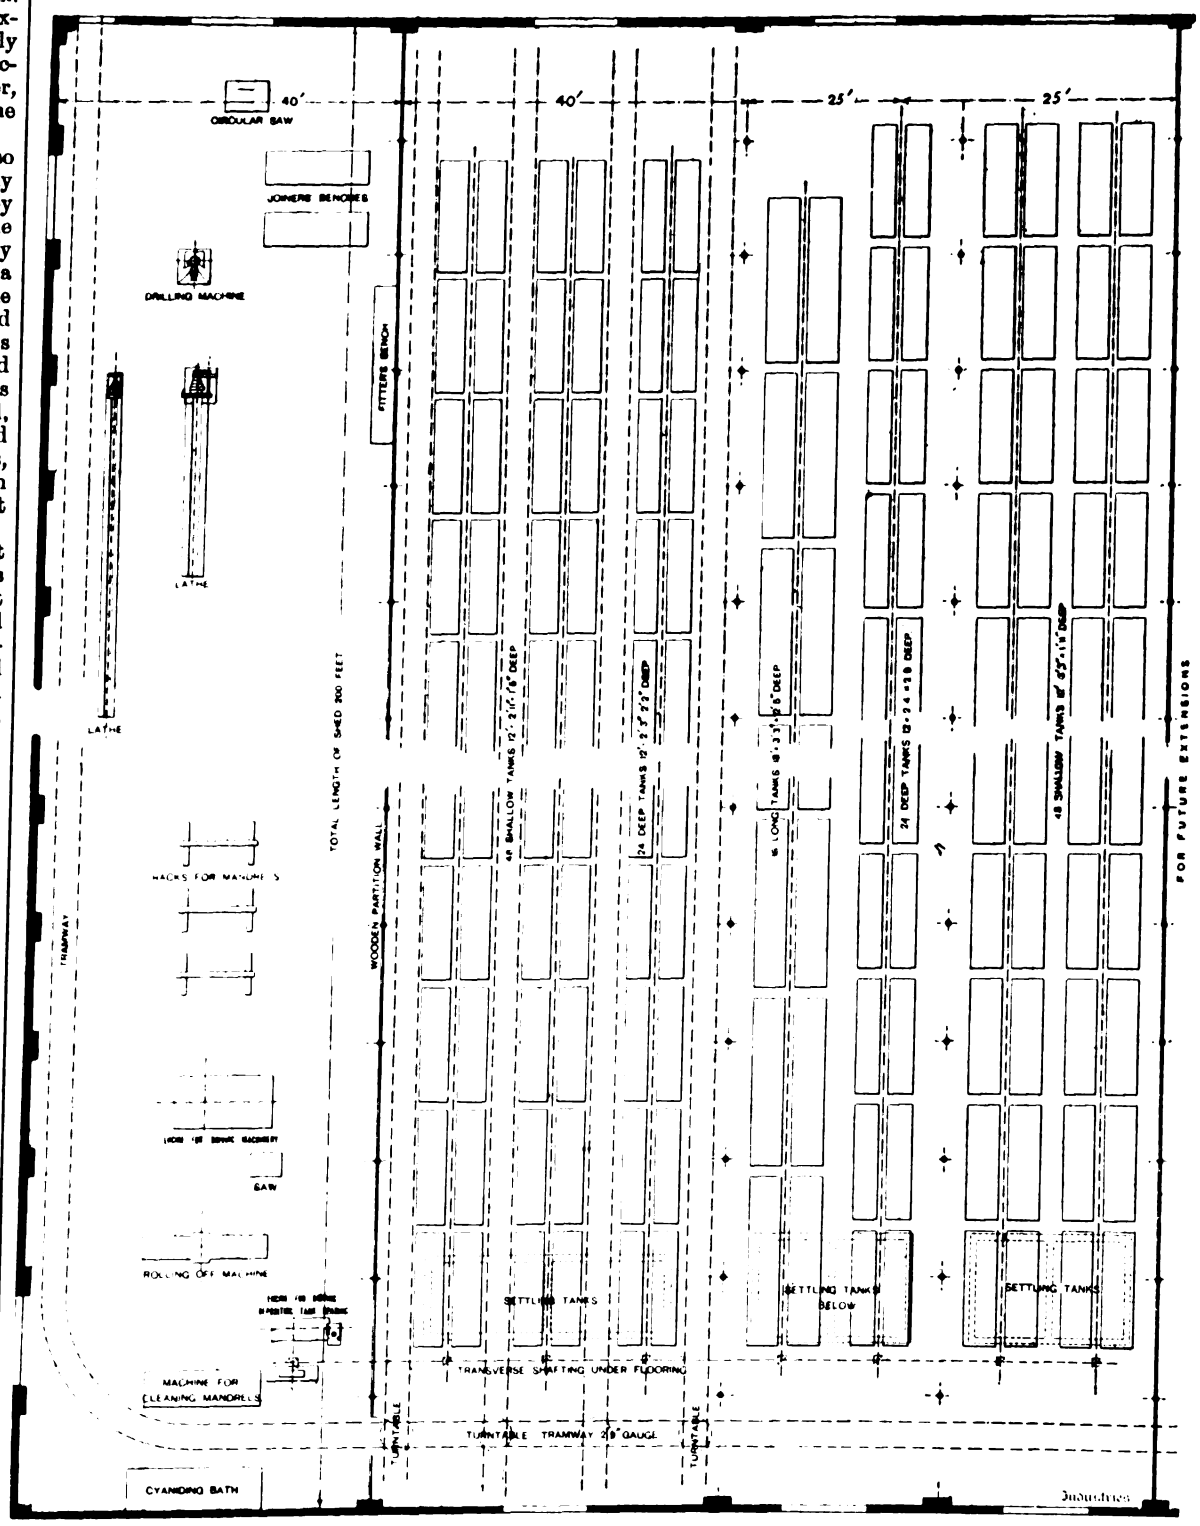

FIG. 2.—GENERAL PLAN.

Digitized by Google

Elmore copper are not more remarkable than its chemical qualities are said to be. Of this no actual demonstration was given, but statements were publicly made which are deserving of the closest consideration. The high tensile strength accompanying the great extension given above would tend to show that a material with such properties could scarcely be copper as we ordinarily know it. Much may be ascribed to the absence of impurities; indeed, Professor Roberts-Austen maintained recently, at a meeting of the London Section of the Society of Chemical Industry (see *Industries*, Vol. X., page 42), that copper probably exists in an α and β condition, similar to those states proved to exist in the case of iron, and that the known influence of impurities may be due to their determining which of these states the copper may be in; thus we may, for the first time, have in Elmore copper to do with one or other of these allotropic modifications. But instead of the difference in quality being due to absolute purity, it may rather be ascribed to the presence of one particular impurity—viz., hydrogen. Indeed, this suggestion has been made by Mr. Bertram Blount, who has quoted the known case of the modification of iron which is deposited in the aciertype process, which is generally considered due to combined hydrogen. It is well known that copper has an extraordinary affinity for hydrogen; G. S. Johnson has shown that copper reduced from its oxide by hydrogen retains traces of that element with extraordinary tenacity, far more strongly than can be accounted for by supposing it due to occlusion. Against this idea may be set the statement of Mr. Frank Elmore, that he has not detected hydrogen in the copper produced by this process, and, further, that the e.m.f. used is not high enough to decompose water. This last is a serious objection, but not insuperable, as the e.m.f. necessary to deposit an alloy of copper and hydrogen may be less than that required for the elimination of hydrogen alone. An instance in point of the affinity of one element for another markedly modifying the total energy required for its reduction is the comparative ease with which aluminium may be reduced in presence of copper on account of its strong affinity for that metal.

To whatever cause we may ascribe this difference it seems pretty certain that the difference is real. Mr. F. Elmore has experimented with copper vessels for containing crude ozokerit and similar materials. Usually sufficient corrosive impurities are present in such substances to cause candle-makers to have recourse to silvered or platinised basins and other receptacles, but Mr. Elmore's experiments go far to show that copper will shortly take their place. He has compared the powers of withstanding corrosion of vessels of Elmore copper and of copper produced by the usual methods, and finds the former scarcely attacked by influences that seriously affect the latter. The company is so impressed by the value of this observation that it proposes to set up plant for the production of dishes of copper, or coated with copper, forthwith. Of course some modification of the apparatus will be necessary; instead of the ordinary motion of the burnisher, one must be devised to deal with concave shapes, or, if not that, at least with discs which may afterwards be spun into the required form.

A careful examination of what is at present to be seen at the Elmore Company's works leads to the conclusion that the process has been carefully thought out, and difficulties that would not at once be obvious have been foreseen and provided for. The fundamental idea of the process—continuous burnishing during deposition—may be said to have proved its value, and the one other thing needed to ensure commercial success is a low cost of production. Many factors here come into play. It may at first seem obvious that any process in which electrical energy obtained from fuel through those wasteful intermediaries—the boiler, engine, and dynamo—must be unable to compete with one in which heat from the same fuel is used directly. But the consumption of fuel in the ordinary refining process is altogether in excess of that actually necessary to fuse, and maintain in a state of fusion for the requisite time, the copper to be refined. Further, it must not be overlooked that the energy required to deposit the copper on the cathode is only that needed to *transfer* copper from anode to cathode. None is needed for reducing the copper from oxide or other compound to metal; that has already been done by the producer of Chili bars. A more serious objection is the slowness of the process. This may be minimised by increasing the current density to the extreme limit of safety; possibly the use of more than one burnisher traversing the same cylinder might raise this limit. The company, whose immediate business such commercial considerations primarily are, feel convinced that the cost of production will be much lower than by older methods. Should this claim be made good, it appears to us that, where copper goods of high quality and of such shapes that a burnisher can be caused to traverse their surfaces by any simple mechanical motion are required, the Elmore process will prove a formidable competitor to the methods at present in vogue.

Notes.

COAL IN BRAZIL.

ALTHOUGH the deposits of coal in Brazil are by no means as important as those of iron ore, still there are many provinces where coal exists and is worked, while a search would probably lead to the discovery of other beds. Graphite is also found, and saltpetre has for a considerable time been worked. The Government grant liberal terms to those looking for and developing mineral fields.

THE ELECTRIC LIGHTING OF TRAINS.

PROFESSOR KOHLRAUSCH has reported on the experiments which have been in the electric lighting of railway trains between Cannstadt and Stuttgart, and his conclusions are that such lighting must be independent of the locomotive, and that it must be on the accumulator system. He disapproves of carrying a dynamo, owing to the consequent increase in the number of couplings in the train, and advocates charging the accumulators by means of fixed engines at various stations, and changing the batteries when approaching exhaustion. This system is stated to have been successfully carried on by the Oërlikon Company on Swiss railways.

THE TRADE OF DENMARK IN 1889.

THE trade of Denmark in 1889 with foreign countries amounted to 3,375,000 tons, of which 2,792,500 tons belonged to imports and 583,090 tons to exports. The estimated value of the whole trade with foreign countries amounted to £28,534,000, in which imports figured for £16,906,000 and exports for £11,628,000. Of this last amount £9,056,000 were native produce, and £2,000,000 foreign goods re-exported. Taking the volume of trade, it is seen that there are 200,000 tons more than in 1888, and 350,000 tons more than the average for the last five years. The increase is shared both by imports and exports. As regards values, there is an advance of £3,000,000 over the previous year, which is noticeable both in imports and exports.

SHIPBUILDING YARD AT DANTZIG.

A REPORT to the Foreign Office from Dantzig states that the only recent public work of importance there is an extensive shipbuilding yard which is being built by Mr. Schichau, the well-known torpedo-boat builder, of Elbing. The site is on the south side of the river, just outside the fortifications. It adjoins the line of railway to Stettin, so that Mr. Schichau will have every convenience for the carriage of all he requires to carry on his business, which, although only said to be a branch of the Elbing works, must in time become the most important of the two places, on account of the greater depth of water at Dantzig as compared with Elbing. The making-up of the ground alone, in order to obtain a secure foundation for the requisite buildings, has given employment to a large number of people. For this purpose Mr. Schichau has purchased a sand hill about half a mile from his site, and he is at present engaged in transporting the sand to its destination by means of an aërial line which passes some 40ft. above the high road, railway, and adjoining properties. Mr. Schichau is said to have already received numerous orders, which only await the construction of the slipways to be put in hand.

EUROPEAN COMPETITION IN SHIPPING.

OUR large shipping companies are beginning to feel rather keenly the competition from German and French lines of steamers, sailing not only from Continental ports but also from British ports. A few days ago the new North German Lloyd steamer "Havel," which was built by the Vulcan Company, at Stettin, sailed from Southampton, and is intended to form one of the regular German liners from that port, and great things are expected of her in the way of speed. She is the sister ship of the "Spree," which ran nearly 20 knots an hour with an indicated horse-power of 13,000. Two other vessels to be added to the Atlantic fleet will also be of Continental build. The Hamburg-American Company, the owners of the "Normania," which was built at Fairfield, Glasgow, will, in a few months, place another German-built steamer, with a 20 knot speed, on the Southampton route, so that that port will be well supplied from German sources alone. The French Compagnie Générale Transatlantique is having a large fast steamer built at the Forges et Chantiers de la Méditerranée at Havre. This competition is evidently stirring up the Cunard Company, who, we understand, are about placing orders for four new steamers, which are intended to beat everything afloat as regards speed. The Atlantic race is thus evidently far from ended, and it will be interesting to note the developments in marine engineering and shipbuilding resulting from this contest.

SMOKE ABATEMENT IN THE WEST OF SCOTLAND.

ABOUT three months ago we referred to a meeting which was held in Glasgow for the purpose of promoting a movement for the abatement of the smoke nuisance in the West of Scotland, and, judging from the speeches made and the representative nature of the Committee appointed, we expected that very rapid progress would be made in the solution of the problem. The first thing wanted was, of course, money to carry on the necessary experiments, and the Committee thought that from £2,000 to £3,000 might be profitably spent in the investigation, but we are sorry to observe that the appeal for funds has met with a very small response. It was sent to upwards of 3,000 persons, and only 161 responded with subscriptions amounting to a total sum of £485, which is, of course, quite inadequate for the purpose. The Committee stated at a recent meeting that as the appeal was made at the end of the year it may have been overlooked, and they decided to postpone any definite decision for another month, in the hope that the public might see their way to give the necessary assistance to enable them to carry out the proposed investigations.

MODERN PHYSICS.

So many people regard the atomic theory as a solid statement of fact, and the ether as existing "stuff," that engineers are now probably open to assimilate more scientific notions. Modern science declares that energy is much the same kind of thing as matter. Though it has no inertia, and is not acted on by gravity, it is indestructible and can always be localised like matter, and presumably occupies space as matter does, but independently of it. If energy disappears in one place it appears somewhere else, and in the meantime it moves from one place to the other. Professor Poynting, in his papers, which have formed the basis of some of these theories, carefully pointed out that he made use of assumptions; but that has been forgotten. Modern science also declares that action at a distance does not exist. The argument is that we cannot conceive it. Many people say they can conceive action at a distance quite as well as atomic lumps rattling together, but that is by the way. Modern science says, "what is inconceivable does not exist." As conceivability depends on experience, this is another way of stating that modern science has experience of the whole universe. Being told that a "pull" does not exist in Nature, and Professor Poynting having shown how energy moves about, we gather from the teachings of modern science that when a portable engine drives a thrashing machine, the energy goes from the engine to the thrasher, through every part of the universe except the belt. The belt is the only thing made or created that does not help to drive the thrasher. There are many other interesting cases of a similar kind, but perhaps one is enough to assimilate at a time.

THE COTTON INDUSTRY.

THE cotton spinning section of the staple industry is in a much worse position than at the beginning of the year; in fact, the tone is now somewhat depressed. Owing to the great decline in raw American cotton, coptwist and weft have been very difficult of sale, and values of yarn have declined at a greater rate than raw cotton. At the present time the margin between cotton and yarn shows little more than change for a shilling. The position is such that already there is a discussion going on privately as to the desirability of organising general short time. If this were attempted it is not at all certain that spinners as a body would adopt half hours, as many are better situated than others. Be that as it may, the position is discouraging to spinners, and at the moment there are no favourable prospects. Weaving, too, as distinct from spinning, is in a poor way. It is said that in Blackburn alone there are 15,000 looms standing idle, whilst in Burnley there are numerous loom sheds working short time. Altogether the cotton industry is going through a critical time. The supply of cotton will be large for all users. The current American cotton crop estimates are now 8,250,000 bales.

Patent Record.

APPLICATIONS FOR PATENTS.

The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

9th February, 1891.

2299. Burnside, G. ..... Mining machines.
2300. Sutcliffe, R. ..... Tunnelling machines.
2302. Priestman & Priestman Dredging and similar machinery.
2329. Tout, J. R. ..... Cock or valve.
2337. Evers, M. ..... Gas engines.
2338. Brain, C. H. ..... Fluid pressure engines, applicable also as pumps.
2345. Cook, H. ..... Amalgamator.
2349. Juel & Ryan ..... Apparatus for purifying wood pulp.
2352. Wells, C. ..... Steam engines.
2353. Payton, W. ..... Apparatus for operating throttle and similar valves from a distance.
2354. Payton, W. ..... Engine governors.
2355. Payton, W. ..... Tool holder for drills, taps, and similar tools.
2356. Morris, H. B. ..... Machines for making wire netting. (5th September, 1890.)
2364. Ghosh, A. S. ..... Air pumps.

10th February, 1891.

2372. Bell, H. ..... Chucks.
2374. Barrott, L. ..... "Gin rollers" used in cotton gins.
2376. Morton, G. ..... Jacquard machines.
2377. Morton, C. H. ..... Gas reversing valves for open-hearth furnaces.
2384. Cartwright, G. A. ..... Knitting machines.
2387. Fricke, Turner, & Dunn Ordnance.
2398. Fraser, P. ..... Forging machines.
2401. Grew, F. W. ..... Machinery for washing grain.
2402. Douglas & Nicholls ... Metallic packing for shafts and spindles.
2408. Hanson, R. ..... Rocking bars of marine boilers.
2410. Wyman, H. ..... Looms for the manufacture of tufted fabrics.
2415. Barker, R. W. ..... Rotary engines (*Meyer*).
2422. Jones, E. C. ..... Gas-fired furnaces for boilers.
2439. Lake, H. H. ..... Apparatus for dyeing straw goods (*Searer*).
2443. Westinghouse, Jun., & Schreuder ..... Railway switch and signal apparatus.
2452. André, U. ..... Hydraulic mains for gas-making apparatus.
2459. Edwards, E. ..... Chuck for lathes (*Rambaud*).

11th February, 1891.

2465. Balfour, J. ..... Seed rolling and crushing machine.
2467. Murawski, H. ..... Furnaces.
2487. Terrot, C. ..... Circular knitting machines.
2512. Longridge, Cawley, & Austin ..... Shearing machinery.

12th February, 1891.

2525. Schippers, F. G. ..... Apparatus for operating Corliss valves of steam engines.
2527. Hodgson, Leeming, & Tetley ..... Appliances for operating the healds of looms.
2530. Boyd, A. ..... Mechanism for operating the steam valves of rotary engines.
2537. Houlden, H. W. ..... Steam engine.
2543. Redford, P. ..... Automatic vacuum brakes.
2553. Crawford, M. ..... Manufacture of balls for use in ball mills for grinding ores.
2569. Griffiths, James, & Hunt Rotary engines.
2572. Norton, J. A. ..... Feed apparatus of machine guns.
2573. Hammesfahr, E. ..... Crank plate mechanisms.

13th February, 1891.

2583. Wilson & Burrell ..... Steam engines.
2593. Binns & Snowden ..... Jacquard machines.
2595. The Pratt and Whitney Company ..... Machines for drilling gun barrels.
2596. The Pratt and Whitney Company ..... Machines for rifling gun barrels.
2601. Bodmer, G. R. ..... Hydraulic motors.
2605. Musgrave, W. M. ..... Governing apparatus of steam engines.
2623. Musgrave, J. V. ..... "Square motion" combing machines.
2624. Higginson, J., Jun. ..... Centrifugal governors.
2630. Hardwick & Robinson ... Punching mechanism for serrating the cutting edges of masons' tools.
2633. Hewitt & Morgan ..... Fog signalling apparatus.
2634. Edwards, E. ..... Water tube boilers (*Willmann*).
2649. Smith, W. ..... Motive power engines.
2662. Lange & Chauvin ..... Apparatus for the manufacture of looped and pile fabrics.
2670. Tenner, A. ..... Platen printing machines adapted to print from a continuous web.

14th February, 1891.

2676. Haythorn & Stuart ... Frictional clutches and couplings.
2680. Horsfall, J. T. ..... Temples for looms.
2681. Stelling, F. H. L. ..... Looms.
2684. Heald, Walmsley, & Walmsley ..... Shuttle guard for looms.
2685. Kaye & Crowther ..... Warp sizing machines.
2687. Hengst, C. F. ..... Rotary steam engine.
2692. Dunlop, J. ..... Steam engines.
2721. Thompson, W. P. ..... Apparatus for turning oval or other shaped objects (*Hansen & Schmidt*).
2730-1. Moore, F. ..... Compound pumping engines. (6th August, 1890.)
2737. Lock, C. ..... Gear wheels.
2741. Horn, W. W. ..... Automatic car coupler (*Reid & Scott*).
2744. Varchavki, M. ..... Sewing machines.

ELECTRICITY.

9th February, 1891.

2334. Eyre & Graham ..... Electrical communicators for use on public vehicles.
2360. Cheswright, H. T. ..... Accumulator plates.

10th February, 1891.

2417. Matthews & Cruickshank ..... Voltmeter and ammeter.
2418. Matthews & Cruickshank ..... Accumulators.
2433. Perry, J. ..... Continuous current transformer.

13th February, 1891.

2642. Mercadier, E. J. P. ..... Telephone receiving instruments.
2654. Forbes, Sir C. S. ..... Primary batteries.
2664. Atkinson & Atkinson ... Mining machinery.

14th February, 1891.

2677. Parsons, C. A. ..... Electricity measuring and recording instruments.

CHEMISTRY.

9th February, 1891.

2326. Smith, A. P. ..... Separation of iron and nickel from solution of their sulphates.
2343. Webb, T. G. ..... Apparatus for concentrating sulphuric acid.
2361. Alzugaray, J. B. ..... Metal alloys.
2362. Wilcox, Butterfield, & Batchelor ..... Manufacture of whitelead and other pigments.

11th February, 1891.

2499. Heraens, W. C. ..... Apparatus for concentrating acids.

13th February, 1891.

2611. Graham, Davis, & Davis Apparatus for the concentration of sulphuric acid.
2673. Darby, J. H. ..... Manufacture of steel.

14th February, 1891.

2682. Levinstein, I. ..... Colouring matters.

MISCELLANEOUS.

9th February, 1891.

2309. Marsden, S. ..... Lock nut.

10th February, 1891.

2378. Allcard, A. A. ..... Adjustable spanners.
2421. Lownes, P. W. ..... Wrenches.
2450. Carpenter, D. H. ..... Combined nut and pipe wrenches.

11th February, 1891.

2468. Beech, H. ..... Automatic fire-extinguishing sprinklers.

12th February, 1891.

2552. Tresidder, T. J. ..... Compound armour plates.
2576. Fuller, F. C. ..... Taps.
2578. Redfern, G. F. ..... Packing for steam engines, &c. (*Armengaud*).

13th February, 1891.

2592. Tweedale & Tweedale Prevention of smoke in steam boilers or furnaces.
2639. Blackburn, W. ..... Composition for removing scales from boilers. (5th September, 1890.)

14th February, 1891.

2719. Dugdale & Pogson ..... Rail joints.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

475. Sack, Von Maltitz, & Ziegel.
2150. Rowley.
2242. Hlawaty & Friedmann.
2387. Pollock.
2504. Wynne.
2544. Chenhall.
2632. Thompson (*Stehlik*).
2766. Lock.
2850. Stott.
2892. Horn (*Dean*).
3001. Gohmann.
3159. Cresswell & Heslop.
3240. Brehier & Talbot.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

MECHANICAL STOKERS.—*J. Proctor, Burnley, Lancashire.*—The stokers here referred to are for the purpose of automatically feeding the fuel to steam boiler furnaces, and are constructed in the following manner, reference being made to the annexed illustrations, in which Fig. 1 is a longitudinal vertical section and Fig. 2 a partial front elevation of such a mechanical stoker:—The furnace flue A has attached to its front end the coal hopper B, from

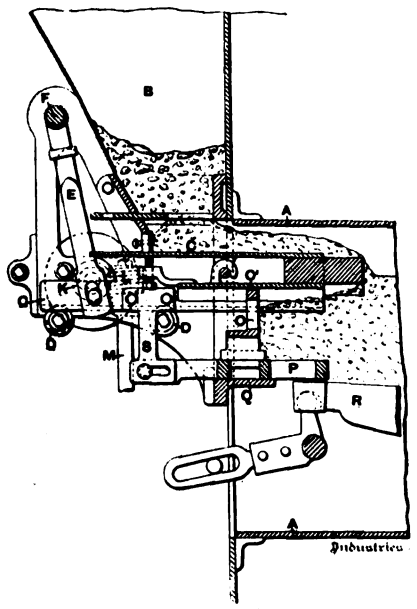

FIG. 1.

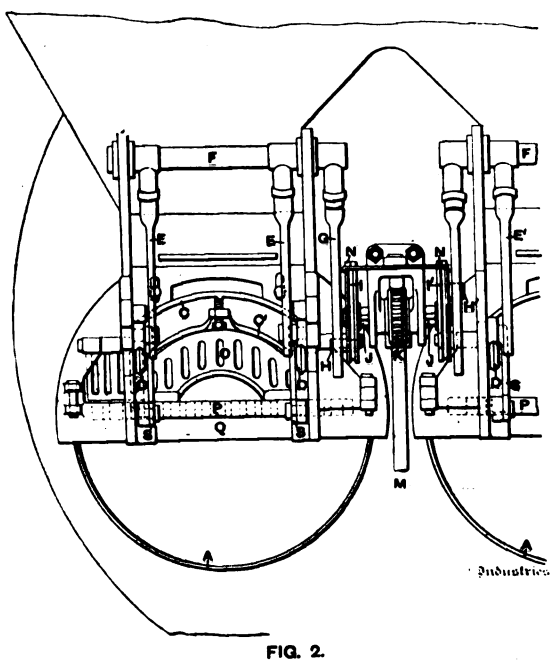
which the coal is fed on to a slide or carriage composed of two arched plates C C¹, fixed together and running on rollers D, and between the inner ends of which a tile or slab of fire-clay is fitted. The carrier is actuated by levers E E¹ fixed on or cast to a rocking shaft F carried by side plates. These levers E E¹ are actuated by means of slotted levers G caused to rock by crank pins H H¹ and plates I I¹ driven by a transverse shaft J, worm wheel K, and worm L on the vertical shaft M, which is driven by any convenient means. By keying the plates I I¹ by means of a feather on the shaft J either of the crank pins H or H¹ can be moved out of gear with its lever G or G¹ as desired. The fixed screws N hold the plates I I¹ in working position by being set in the grooves in the edges of the said plates (see Fig. 2). Below the fire door O is a plate P perforated or gridded, which moves in and out on the dead plate Q and over the gap between it and the front end of the fire-bars R. This plate is connected to C by an arm S and operated thereby, so helping to push forward the coal fed into the furnace by the slide. Claims: (1) In combination with the open mouth of the fuel hopper, an arched or stepped carrier or fire-clay slab moving to and fro beneath the said mouth and carrying the fuel forward into the furnace and depositing the same upon the moving fire-bars substantially as



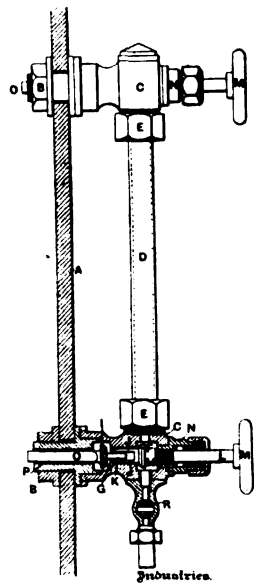


FIG. 2.

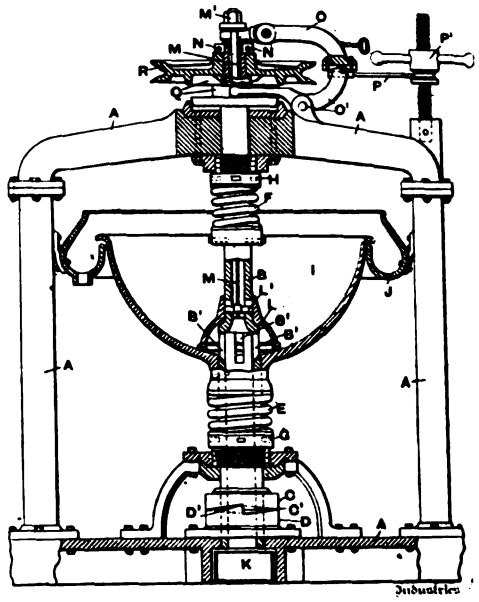
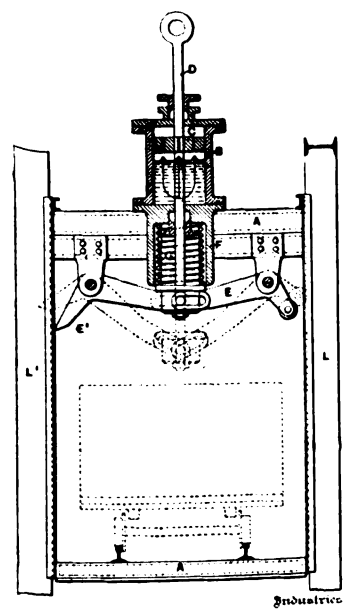
described and illustrated; (2) the combination with a feeding or distributing and coking apparatus, of a plate, preferably gridded, or equivalent device, moving to and fro beneath the said apparatus and over the dead plate and fire-bar ends, substantially as and for the purposes described.—No. 3186. February 28th, 1890. 8*d*.

VALVES FOR HOT GASES.—*J. van Langen & L. Cooper, both of Leeds.*—The valve proper is in the form of a hollow disc or plate provided with a hollow rim or flange adapted to dip into an annular cup containing a suitable liquid or solid packing material. This valve is mounted on a pair of hollow spindles, which receive cold water at the lower end by means of a flexible pipe, and discharge it, after circulating in the valve, at the top through another flexible pipe. The valve casing is of cast iron, containing the valve seating and gas inlets and outlets, situated above and below the valve seat respectively, and also a lower and upper stuffing-box for the lower and upper valve rods. Around the upper stuffing-box is formed a flange, between which and the stuffing-box water is circulated. The casing proper is provided with a closed jacket for cooling water, which surrounds the gas inlet and outlet, the valve chamber, and lower stuffing-box. The cooling water is admitted through a pipe connected to the lower lid connecting the lower ends of the inner and outer casing, and after circulating in the annular groove between these passes out through a pipe connected to the upper end of the outer casing. This pipe extends upwards above the annular receptacle surrounding the upper stuffing-box, and terminates in a double elbow connection, from which the water is led downwards through one pipe, and the steam generated escapes upwards through a second pipe. A small branch pipe from the exhaust pipe below the double elbow connection supplies water to the annular receptacle around the upper stuffing-box. Four claims are made, embracing the general construction of valves for governing the passage of heated gases, substantially as described.—No. 4225. March 18th, 1890. 6*d*.



WATER GAUGE FOR BOILERS.—*J. McEwen, Liverpool.*—The invention refers to means whereby the passages from the boiler to the gauge are automatically closed should the gauge glass be broken. Referring to the annexed illustration, which is a part sectional elevation, A is the front plate of a steam boiler to which the water gauges are attached by the nuts B. C are the bodies or casings of the water gauges, D the gauge glass or tube, E the nuts for securing the gauge glass or tube in position, and R the usual blow-off tap. Each body or casing C is provided internally with the valve faces or seats F and G, against which the

valves H and I operate. The valves H and I are fitted with the interlocking fork ends J and K, by which the valve I is rotated when the valve H is operated by turning the hand-wheel M, thus maintaining a clear passage between the valve faces or seats F and G each time the hand-wheel M is rotated. The valve H is attached to the screwed spindle L provided with the hand-wheel M, the latter being for the purpose of operating the valves H and I when necessary. The spindles L pass through the stuffing boxes N in the usual manner. The valve I is fitted with the stem or guide O, which extends through the outlet P leading from the boiler, and is provided to prevent the outlet P becoming choked with deposit. From the above it will be seen that should the gauge glass be broken the valve I would be forced forward, so closing the passage from the boiler to the gauge glass. If the valve fails to close automatically the passage may be closed by valve H, as will be understood. After the gauge glass has been replaced I can be forced from its seat by means of the fork on the valve J. Claims: (1) In water gauges for steam boilers the use of the valves I for automatically closing the outlets for steam and water in case the gauge glass or tube breaks; (2) in water gauges for steam boilers the use of the valves H for closing the outlets for steam and water in case the automatic valves I fail to operate; (3) in combination with the valves H and I the use of the interlocking fork ends J and K, arranged to operate or rotate the stem or guide O in the passage P for the purpose specified; (4) the construction, combination, and arrangement of parts forming the improvements in water gauges for steam boilers, substantially as described and illustrated.—No. 4131. March 17th, 1890. 8*d*.



ADJUSTABLE SPANNER.—*W. Ash, Walsall, Staffordshire.*—The spanner constructed according to this invention consists of a suitable flat metal bar or handle, on the end of which is formed an arm projecting at right angles to the handle. Sliding on the bar is the sliding jaw, in one part of which a slot is made, and pivoted in the upper part of this slot is one end of a curved catch or pawl, adapted to engage notches formed on one side of the handle. A helical spring placed in the slot in the moving jaw presses against a short end of the catch, so holding the catch in engagement with the teeth on the handle until raised by means of a suitable handle formed on the said short arm. In other arrangements the catch is held in engagement by means of a flat spring, and also two catches or pawls are used instead of one, the catches in this case being pivoted on the opposite sides of the adjustable jaw, and engaging teeth formed on the wider sides of the handle. Claims: The improved moving spanner in which the moving jaw has one or more spring catches arranged substantially as and for the purpose described.—No. 4345. March 20th, 1890. 6*d*.

ORE CONCENTRATORS.—*W. P. Thompson, London.* (*C. E. Seymour & C. F. Staver, both of Hurley, Wisconsin, U.S.A.*).—The annexed illustration shows a part-sectional elevation of an ore concentrator embraced by this invention. Running in bearings

on a suitable frame-work A is a vertical hollow shaft B. This shaft receives a vertical reciprocating motion by means of the collar C thereon and a second collar D fixed to A, having respectively diametrical cams C¹ D¹, which so engage one another as to produce the said reciprocation. The shaft B is normally forced downwards by means of springs E and F, the tension of which may be adjusted by means of screwed sleeves G H. At about the middle of B is fixed the concave bowl I, into which the pulverised ore, &c., together with water, is fed. Around the upper edge of I is an annular chamber J, supported by A, into which the waste from I is caused, by centrifugal force, to escape. The shaft B is provided, at about the bottom of I, with four holes B¹, through which the contents of I may escape into a pan K. These holes B¹ are governed by means of a cone-shaped valve L fixed by means of a bolt L¹, working in slots in B, to a rod M. The upper end of M carries a nut M¹, between which and a collar N on B the forked end of a lever O, pivoted at O¹ and governed by a flexible rod P and nut P¹ as shown, may be forced, so raising M together with L. The other end of O, also forked, projects into a groove in a friction wheel Q capable of longitudinal movement on B, but revolving therewith. This wheel Q is for the purpose of engaging and disengaging the driving wheel R with B as required. Nine claims are made.—No. 15021. September 23rd, 1890. 8*d*.

LIFTS.—*A. Eichert, Hohenzollern Mine, near Beuthen, Silesia, Germany.*—The object of the inventor is to prevent the articles or persons in the cage of a lift being thrown out in case of the rupture of the cable. The accompanying illustration shows an

appliance for this purpose. Upon the cage A is arranged a cylinder B, in which is a piston C, through the medium of whose rod D both the junction of the ropes or chains at the top is ensured and the catch levers E E' are operated by the piece S. The piston C is provided with a number of parallel openings of sufficient size, and the cylinder is partly filled with a suitable liquid, such as glycerine. With the cylinder is connected a box F containing a spring G. Should the rope or chain break the operation of this safety device is as follows:—The spring G,

Digitized by Google

which is compressed as the elevator moves up and down, expands in case of breakage, and forces the catch levers E E¹ against the guide ropes L L¹, but at the same time the piston encountering the resistance of the fluid in the cylinder prevents the too sudden action of the catch levers, and consequently the cage comes to a standstill gradually; the piston, in descending, also meets the liquid contained in the cylinder, and under the influence of the spring slowly forces the said liquid through the above-mentioned openings until the levers reach the position indicated in dotted lines, in which the cage is entirely under brake action. Claims: The arrangement as described and for the purpose set forth.—No. 19058. November 24th, 1890. 6*d*.

STEAM HAMMERS.—*E. S. Brett & J. Hazlewood, both of Coventry.*—The invention relates to steam drop hammers. Referring to the accompanying illustrations, Fig. 1 is a front elevation, Fig. 2 a

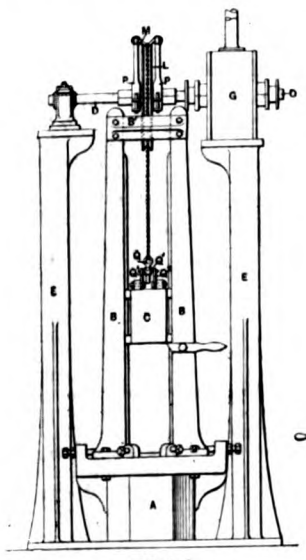


FIG. 1

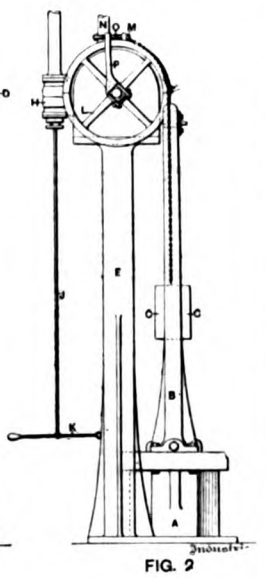

FIG. 2

side elevation, and Figs. 3 and 4 details, of a drop hammer constructed according to this invention. A is the fixed block, at each side of which is fixed a vertical guide B, in which the hammer C slides. Above the top of B B is placed the horizontal driving shaft D, running in suitable bearings on the pillars E E, the shaft D being operated by means of a plate piston F working in a cylinder G (Fig. 3). A suitable steam chest H and valve I is arranged in connection with the cylinder G, and also a rod J and lever K, by which the said valve is operated as desired. The driving shaft D has a loose pulley L, over which the chain connected to C runs. The upper end of this chain is connected to a cross-piece M connected by bolts N and springs O (Fig. 4) to arms P fixed on D. On the upper ends of B B is a cross-piece B¹, on which are fixed cushions, against which the bolts N strike when the hammer C is allowed to fall,

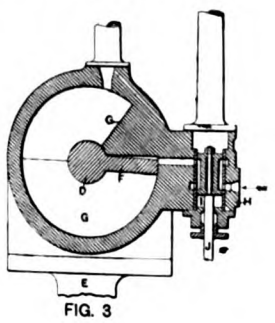

FIG. 3

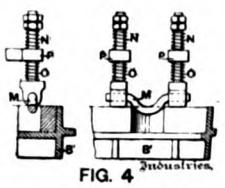

FIG. 4

so preventing piston F striking the interior projection G¹ of G. The length of the chain is made adjustable in order to accommodate the position of the piston F by means of an adjustable bolt Q screwing into a plate Q¹, carried by arms Q² pivoted to C. Five claims are made.—No. 2924. February 24th, 1890. 8*d*.

GAS ENGINES.—*Dr. N. A. Otto, Köln, Germany.*—The invention relates to engines working with a cycle of four strokes, and has for its object a method of maintaining the exhaust valve closed during the compression stroke. According to one method a double-ended lever, pivoted horizontally to the outer end of the cylinder, has one end connected to one side of the igniting slide, the other side of which is connected by a rod to an eccentric on the crank-shaft of the engine. The other end carries a pivoted rod, which ordinarily is held in a position so that it will strike the notched end of the spindle of the exhaust valve, by means of a spring holding it against the hooked end of the actuating lever. Connected to the second or valve-actuating lever is a link connected at its other end to a flexible diaphragm closing a cup-shaped vessel which is connected by a small pipe with either the gas supply pipe or the air inlet of the cylinder. The effect of this arrangement is that when the piston is performing its suction stroke, producing a certain rarefaction in the gas and air supply pipes, this reduction of pressure in being transmitted to the diaphragm cup will cause the diaphragm to be forced inwards by atmospheric pressure, thereby drawing down the rod which normally acts upon the notched end of the exhaust valve spindle, so that it slides under said spindle and allows the exhaust valve to remain closed during the compression stroke. The full pressure being meanwhile restored in the gas and air inlet pipes, and consequently in the diaphragm-cup, the diaphragm is forced outwards, so allowing the exhaust valve operating rod to regain its normal position and so open the exhaust valve as the piston commences its inward expelling stroke. In a modification the inventor connects the pipe of the diaphragm-cup with the interior of the working cylinder. Four claims are made, embracing the arrangement substantially as described, together with modifications as described and modified operating parts.—No. 4823. March 27th, 1890. 8*d*.

LOOMS.—*J. Lindsay & R. Allan, Dundee, N.B.*—The inventors' object is to provide an apparatus applied to the whip rail of a loom for weaving, to impart some elasticity in order to render the beating-up or other strains on the warp less severe than in ordinary looms. For this purpose one side or edge of a curved plate of thin steel of a suitable temper is fixed to the whip-rail in such a manner that it only touches the rail where fixed to it when free. The warps, in passing up from the warp beam to and over this spring whip-plate, bend it more or less according to the tension on them; and when the strain on them is suddenly increased by the beat-up, the spring whip-plate yields further, but immediately springs out to its normal position when relieved. One or more springs may be applied under this plate if required, or instead of the whip-plate being elastic, it may be of cast iron or otherwise rigid, and be pressed outwards by one or more springs, the rigid plate being hinged to the loom framing. Claims: The providing of a loom for weaving with a spring whip-rail or plate, or a spring-pressed whip-plate, substantially as and for the purpose described.—No. 4333. March 20th, 1890. 6*d*.

CRUSHING MACHINES.—*J. C. Cole, London.*—Crushing machines constructed upon the principle of this invention accomplish their object by means of a reciprocating motion imparted to one of a pair of jaws between which the material to be crushed is fed. Referring to the accompanying illustrations, Fig. 1 is a vertical section, and Fig. 2 a plan of such a machine having two pairs of jaws. On the frame A are the two adjustable crushing faces B, against which the movable crushing blocks C C¹ pivoted on rods D work. The head E is given a vertical reciprocating motion by means of the crank on the shaft F. The upper and lower ends of E are connected by means of toggle joints G G¹ G² G³,

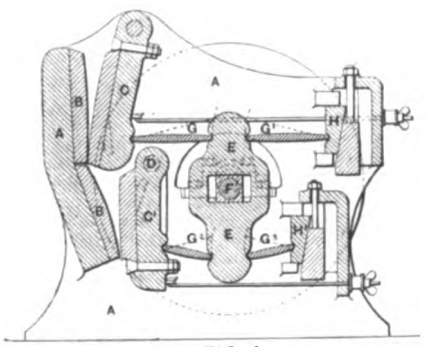

FIG. 1

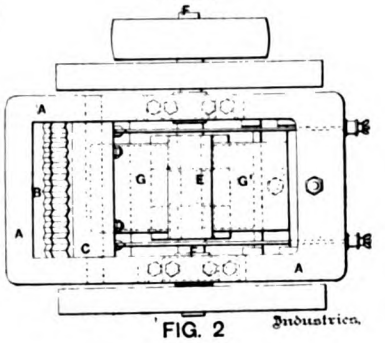

FIG. 2

to the blocks C C¹, the outer ends of G¹ and G³ resting in adjustable blocks H H¹. The disposition of the parts mentioned and the relative lengths of the upper and lower toggles give rise to two double reciprocations of the jaw C¹, while the upper jaw C makes but one double reciprocation to every revolution of the crank or eccentric shaft F. To effect this the parts are so arranged that the upper toggles are in a line, and so close the upper jaw when the crank has given its maximum motion in one direction to the piece E. The inventor also describes modifications in which three pairs of jaws are used, together with other improvements. Five claims are made.—No. 2281. February 12th, 1890. 8*d*.

VICES.—*J. Kenyon, J. Barnes, & R. W. Kenyon, all of Accrington, Lancashire.*—One jaw of the vice (preferably the front one) is, according to this patent, pivoted at or near its base to allow it to turn and adjust itself to the second or back jaw. In carrying this into effect as regards parallel vices the back jaw is constructed in the usual manner with a bracket or base plate, by which it is secured to the bench, and a sliding bar sliding in a slot between the jaw and its base to carry the front jaw. This arm is of L or a convenient shape, and is provided in its lower member with a socket to receive a pin or pivot on the bottom of the front jaw. In the upper part of this jaw a hole is provided, through which the spindle of the tightening screw passes, as well as through the vertical arm of the L slide. The lower end of the jaw is provided with a pivot, which fits into the socket in the sliding arm, and the back of the jaw is turned to the arc of a circle and fitted to rest against the L arm with a lug or tongue projecting into a groove, by means of which the greater part of the strain falls upon the sliding arm. The movable jaw is provided with a catch, which engages with a slot in the sliding arm to retain the jaw when required parallel to the fixed jaw. Claims: (1) A vice having one jaw pivoted at or near the bottom in a supporting slide-bar with an elongated or slotted hole, through which the tightening screw passes, the pivoted jaw being supported above its pivot by the tightening screw, or by a bracket, against which the screw bears as described; (2) a parallel vice having a fixed jaw, a base-plate, and a sliding bar, with or without the upright supporting member which carries the second jaw, and a jaw through which the tightening screw passes, pivoted thereto as described; (3) a vice having the several parts constructed and arranged substantially as described.—No. 4401. May 20th, 1890. 11*d*.

MECHANICAL STOKERS.—*J., T., & J. Vicars, all of Liverpool.*—The invention relates to those mechanical stokers in which the firebars are carried forward in a body from the front to the rear of the grate, and are moved back again in detachments or one at a time. The hopper for supplying the fuel to the stoker, instead of being fixed in the ordinary manner, is hinged at its bottom to the main frame of the stoker, so that it can be readily turned down to expose the front of the boiler for inspection, cleaning of the fire tubes, &c. A suitable hollow jacket in three pieces, secured between the fuel delivery orifice of the stoker and the roof of the furnace mouth, serves as a passage for air from the exterior to the interior of the furnace, the air entering and escaping through suitable perforations in each side of the casing. Claims: (1) A hopper and stoker jointed together in the manner and for the purpose set forth; (2) constructing furnaces with a mechanical stoker and hollow jacket disposed in the manner and for the purpose set forth.—No. 4203. March 18th, 1890. 6*d*.

GRINDING MILLS.—*F. Chapman, London.* (*G. Massey, Sydney, N.S.W.*)—In the annexed illustrations Fig. 1 is a sectional elevation, and Fig 2 a half plan and half horizontal section of a grind-

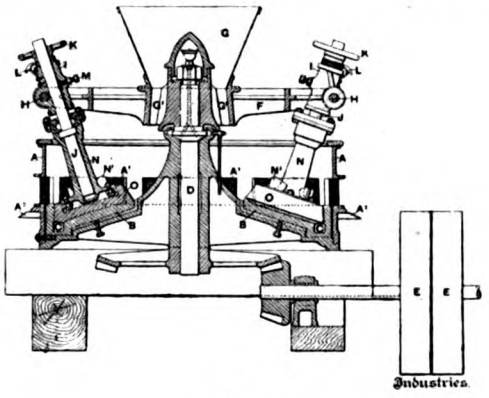

FIG. 1.

ing mill constructed according to this invention. Placed in the annular pan A is an annular grinding race B having a mercury groove C. Running in the centre of A and concentrically with B is a vertical shaft D driven by means of gearing from E and carrying upon its upper end a frame F having a hopper G in its centre for feeding the material to be crushed through holes G¹ into A. This frame F has pivoted on spindles H collars I embracing shafts J, the upper ends of which are screwed so that by means of hand-wheel K they may be raised or lowered, the distance being regulated by means of spring catch L working in a number of indentations in K, the shafts H being, after adjustment, fixed by set screws M. The lower ends of J carry by means of collars sleeves N, having vanes or splashers N¹, on the lower ends of which are bolted the muller heads O formed to suit the shape of the race B. Around A are fixed grates A¹ and a dis-

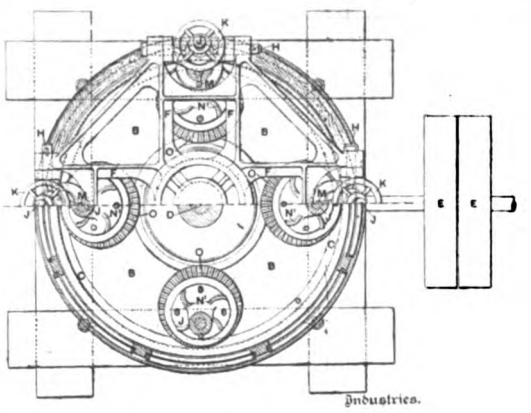

FIG. 2.

charge lip A². By pivoting the collars I carrying the spindles J as described, the muller heads, as the frame F is revolved, will, by centrifugal force, be pressed against the side of A. Six claims are made.—No. 18089. November 10th, 1890. 11*d*.

TUBULAR BOILERS.—*W. Hornsby & R. Edwards, both of Grantham, Lincolnshire.*—The invention relates to the construction of externally fired tubular boilers, constructed of two cylindrical shells of different diameters jointed together end to end but eccentrically, end plates being provided at the outer ends of the shells and at the other end of the larger shell not covered by the smaller one, and tubes are arranged between these plates. At the outer ends of the boilers are arranged fire-boxes forming continuations of the shells. Underneath the front or smaller part is arranged a fire-grate of the ordinary construction, the heated products of combustion from which first pass through the lower set of tubes connected to that part of the larger cylinder not covered by the smaller one, and to the outer end of the larger cylinder or back of the boiler, from thence they pass through the back fire-box, through the tubes running the entire length of the boiler and into the front fire-box, and then to the chimney. Claims: (1) Constructing tubular boilers with two cylindrical shells of different diameters attached together end to end eccentrically, and with tube plates and tubes arranged as described; (2) the manufacture and use of the improved longitudinal tubular steam boiler constructed and arranged substantially as described.—No. 4589. March 24th, 1890. 6*d*.

Digitized by Google

SELF-ACTING MULES.—*G. Hartley, Brierfield, near Burnley, Lancashire.*—The invention consists of an arrangement of parts for automatically controlling or varying the speed of the tin roller shaft, or the spindles which it actuates, while the machine is in operation, so as to relieve the yarn of superfluous twist at the commencement of the draw. For this purpose two grooved driving pulleys of unequal diameter are employed, driven from the same rim-band, and capable of engaging alternately with frictional cones fixed to the tin roller shaft. At the commencement of the "draw" the larger driving pulley is thrown upon one of the cones, so as to drive the tin roller at a reduced speed and relieve the yarn of superfluous twist. After relieving the yarn the larger pulley is withdrawn and the smaller pulley thrown upon the other cone to increase the speed. The shifting movement of the pulleys is effected by means of a lever on the carriage coming, during its traverse, against suitable stationary guides. Claims: (1) The arrangement of mechanism for obtaining an increase or decrease of speed in spinning mules as described; (2) the combination of two speed pulleys of different diameters and friction cones, operating substantially as described.—No. 4110. March 17th, 1890. 6*d*.

SKIN SPLITTING MACHINERY.—*S. Bowron, London.*—In the accompanying illustrations Fig. 1 represents a front elevation, partly broken away, Fig. 2 being a transverse section on an enlarged scale of the principal parts of a skin splitting machine constructed according to the invention. A is the framework of the machine, similarly constructed at both ends, and B are bearings in which are supported shafts C, on which are mounted single flanged pulleys D carrying a broad endless band knife E, which travels across a table F, being kept perfectly level in its course by means of adjustable plates F^1 (Fig. 2). Beneath the knife E is mounted a roller G, the distance between the edge of the knife and the roller being regulated by adjusting screws G, one only of which is shown. On a shaft H are loosely mounted a series of rollers H^1. The skin to be split is placed upon the table J and one edge presented to the rollers G and H^1, which draw it forward, and present it to the edge of the splitting knife E. The roller G is supported rigidly throughout its length by bearings formed at intervals in the trough or casing G^1, and the rollers H^1 are pressed against the upper surface of the skin by means of a roller K, which is covered with indiarubber, and which, whilst imparting motion by surface friction to the rollers H^1, permits them to accommodate themselves to the slight inequalities in the thickness of the skin. As soon as the first portion of the skin has passed between the rollers G and H^1, the under layer is caught between rollers G and G^2, the upper portion being taken up as cut by the attendant. The roller K is enclosed within a metal cover K^1, which is open at the bottom to allow the rollers H^1 to project therethrough. This cover K^1 is mounted on arms K^2, shown broken, on the ends K^3 of which are counterbalance weights, by which means the whole

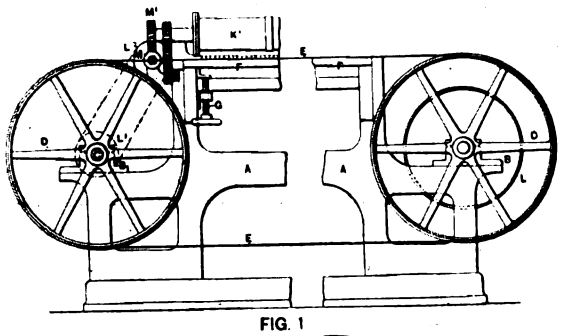

FIG. 1

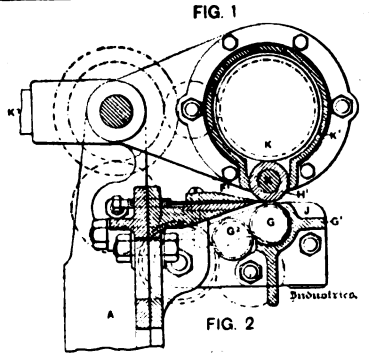

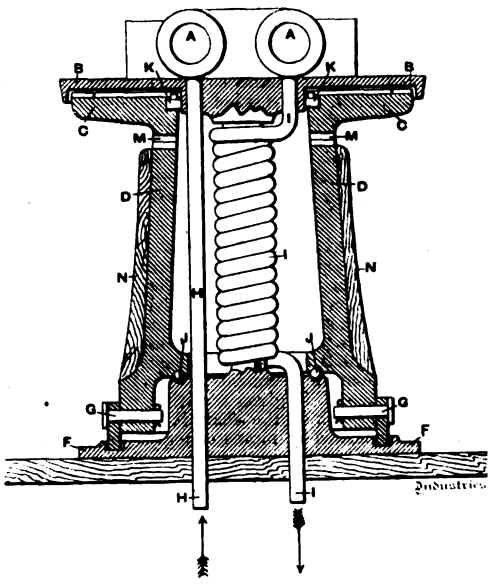

FIG. 2

of the parts H^1, K, and K^1 can be readily raised to afford access to the knife and adjusting parts in connection therewith. Claims: (1) In a machine for splitting sheep-skins the combination of an endless knife E with rollers G and H^1 in the manner described; (2) the combination with knife E and rollers G and H^1 of an indiarubber or other yielding roller K in manner and for the purpose as described; (3) the general construction and arrangement of a machine for splitting sheep-skins as described and illustrated.—No. 20093. December 9th, 1890. 6*d*.

THRASHING MACHINES.—*J. Marshall, Gainsborough, Lincolnshire.*—The aim of the inventor is to provide, in connection with thrashing machines, means whereby they are are fitted for use for thrashing clover or trefoil at one operation. For this purpose a clover shelling drum and "concave" is applied to the tail end of a thrashing machine, so that said drum receives the "cobs" from the upper dressing shoe, after the clover or trefoil has been passed through the ordinary thrashing drum, they being carried over the upper dressing shoe on to a caving riddle, provided for that purpose, and thence being delivered into the barrel of the clover sheller. The shaft of the clover sheller is, at the end situated at the outlet, provided with blades to throw back the seed and chaff, separated in shelling, on to the opposite side of the caving riddle, which separates the seed from the chaff and deposits the latter on the ground at the end of the machine under the barrel of the sheller, whilst the seed passes through the caving riddle and lower dressing apparatus to the elevators, and from thence is delivered into sacks at the other end of the machine. Claims: (1) In combination with a thrashing machine a clover or trefoil shelling drum as and for the purpose described; (2) the arrangement of parts so as to constitute a machine for thrashing or stripping and shelling clover or trefoil, substantially as described.—No. 4167. March 17th, 1890. 6*d*.

STEAM CAPSTANS.—*J. W. Brooke, Lowestoft.*—The annexed illustration shows a capstan constructed according to this invention. A A are the steam cylinders of the ordinary horizontal direct-acting type, having the steam and exhaust passages cast in one therewith. B is the capstan head, to which the cylinders are

bolted. C is the crown wheel. D is the iron revolving barrel of the capstan having holes M M for hand spikes; N N are the wooden whelps fixed round the barrel D. E is the wrought-iron spindle carried by the pawl-pan F. G are the pawls and bolts. H is the induction steam pipe, carrying steam to the cylinders A. I is the eduction coil, which coil is carried outside the spindle E, and forms a condenser for the eduction steam. Ball bearings J and rollers K are provided to reduce friction. The inventor claims in the construction of steam capstans, the utilisation of the annular space between the spindle E and the revolving barrel D for, and the combination therewith of, the steam pipe H and condenser coil I as described, and the general construction, combination, and arrangement of the several and respective parts together constituting the improvements in steam capstans as described.—No. 3724. March 8th, 1890. 6*d*.

ELECTRICITY.

DYNAMOS.—*A. C. Reignier, Paris, France.*—The invention relates to a method of coiling the armature (either of the drum, disc, ring, or other form), whereby more favourable utilisation of the mechanical or electrical energy expended may be obtained. In describing the method as applied to an armature of the drum type, the armature axis, which is fixed, carries the drum made to revolve on ball bearings at each end thereof, and between these bearings a magnetic core is fixed to the axis. The coiling of the armature consists of groups of laminæ, which are successively of insulating material, iron, copper, then iron insulating material again, iron, copper, and iron insulating material, and so on repeatedly. The copper laminæ are extended and serve as conductors which terminate in collecting conductors in the form of rings fixed at one end of the revolving drum, the driving pulley being fixed at the opposite end. The brushes are carried on an arm on a suitable rocker pivoted to the end of the stationary axis. Between the groups of laminæ are bolted wedge-shaped iron rods serving to secure together the several groups of laminæ in the form of a cylindrical armature. Claims: (1) A dynamo machine whereof the armature is built up of, first, a number of similar parts, each consisting of laminæ of iron, copper, and insulating material, each laminæ of copper pushed between two laminæ of iron outside of which are two insulating laminæ, and secondly, of wedge pieces fixing the groups of laminæ, the whole forming a hollow cylinder surrounding a soft iron core, and revolving on ball bearings, the armature being either a drum with Siemens coiling or a ring with Gramme coiling or of any equivalent kind; (2) the general construction of the drum machine described; (3) a modified construction wherein the junctions extend beyond the laminæ of the magnetic sides to parallel insulated rings situated at one end of the machine and of the same diameter as the drum, with brushes bearing on them; (4) a machine of the ring type, having its armature consisting of an annular laminated nave carrying externally iron, copper, and insulating laminæ, as in the drum machine, and internally copper and insulating laminæ connected to the external laminæ and to a collector with diametrically opposite brushes.—No. 3028. February 25th, 1890. 8*d*.

CONCENTRATION OF IRON ORES.—*R. Haddan, London.* (*G Conkling, Glens Falls, New York State, U.S.A.*)—The process of concentration of iron ores embraced by this invention consists in first crushing the ore to particles of about a quarter of an inch in size, and then exposing it in such a granular form to the action of powerful magnets, so that all the particles containing iron ore are separated from the gangue. These particles containing ore are again crushed to particles of about ¼in. or less in size, and exposed to the action of the magnets, so separating the remaining gangue from the iron ore. The separator used for the above purpose is constructed in the following manner:—Running in a suitable frame-work are two rollers, one placed at a suitable distance above the other, and at a suitable distance to one side of it, so that an endless band passing around the rollers will run in a slanting direction. This band runs in such a direction that the crushed ore fed by means of a suitable shoot on to its upper surface is carried upwards and over the higher roller. Situated between the endless band are three or more electromagnets, the poles of which are connected to an iron plate situated close to the underside of the upward travelling part of the band, the ends of said plate extending to near the surface of the two rollers, and being of a width equal to that of the band. Those particles of ore containing iron will be so held to the band by magnetic attraction until carried to the upper surface of the higher roller, where, as it passes away from the attracting magnets, it is released and so, as the band continues its course, is thrown from the band as it passes around the upper roller. The gangue separated from the iron containing ore rolls down the band and is collected in a suitable receptacle as it falls. Claims: The process as described —No. 18636. November 18th, 1890. 6*d*.

CHEMISTRY.

DYESTUFFS.—*S. Pitt, Sutton, Surrey.* (*L. Cassella & Co., Frankfort-on-the-Main, Germany*).—The invention relates to the production of new dyestuffs by the action of dimethylamine upon fluoresceine. The following is an example of the process embraced by the invention:—33 kilos of fluoresceine dissolved in 150 litres of alcohol, and 30 litres of an aqueous solution containing 40 per cent. of dimethylamine, are heated in a closed vessel (autoclave) for twelve hours to 175°–180° C. The contents of the vessel are diluted with 100 litres of water, and 8 kilos of caustic soda are added. That part of the dimethylamine which did not combine with the fluoresceine is separated by distillation, and by the adding to the remaining solution at a temperature of from 70°–80° C. of 50 kilos acetic acid of 50 per cent., the rhodaminol formed is caused to precipitate. This may be purified by repeatedly dissolving its sodic salt and precipitating it by means of common salt, filtering, and adding some muriatic acid, which causes the separation of crystals of the chlorhydrate of tetramethylrhodamin. Claims: (1) The process of preparing basic dyestuffs from fluoresceine or fluoresceine ethers by heating these substances with dimethylamine; (2) the new products which result from the process described.—No. 4904. March 28th, 1890. 4*d*.

MISCELLANEOUS.

SUPPORT FOR SHIPS' BOATS.—*C. J. van Sluijs, Ymuiden, & C. S. Jzn, Velsen, both of Holland.*—The support, constructed on the principle of the invention, is for the purpose of providing a secure resting place on the deck of the vessel for the boats, and also to provide means whereby the latter may be rapidly launched. In the accompanying illustrations Fig. 1 is an end elevation, Fig. 2 a side elevation of the rear support (the front support being of a similar construction), and Fig. 3 a plan of a deck support for ships' boats, constructed according to this invention. Two central supports A, supporting the main weight of the boat, are supported by means of hinged levers B, hinged at their lower ends to sliding blocks C, sliding on the plate E and actuated so as to be caused to recede from or approach one another, as desired, by means of a left and right-hand screwed shaft F running in bearings G. Hinged to the top of G are rods H hinged at their upper ends to the side supports I carried on the upper ends of the rods J. These rods J are hinged at J^1, the hinged part being embraced by a sleeve K (Fig. 4), capable

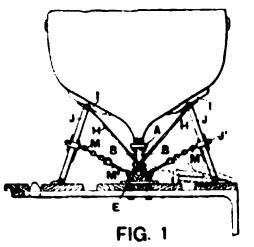

FIG. 1

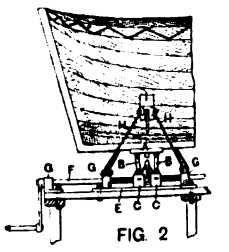

FIG. 2

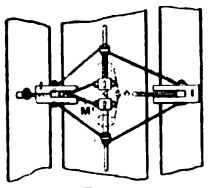

FIG. 3

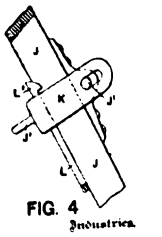

FIG. 4

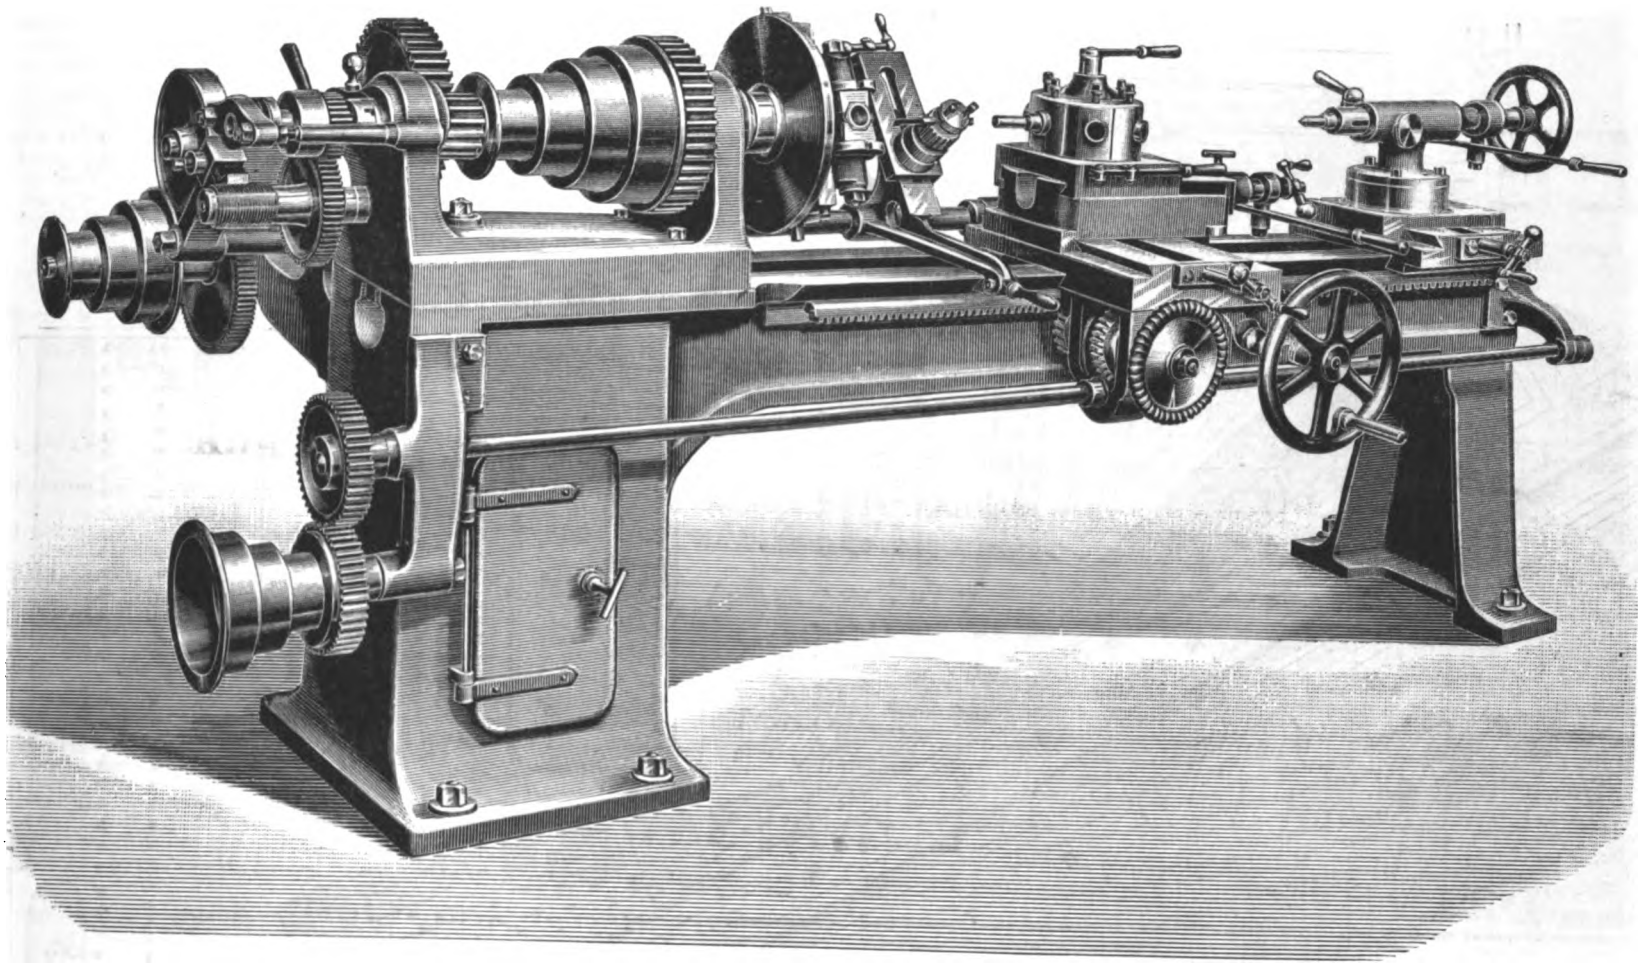
of a slight transverse movement, and carrying a spring L, the end L^1 of which enters a notch in one part of the rods J, so holding them in the position shown. The sleeve K is connected by means of chain M and toggles M^1 to the blocks C. From the above it will thus be seen that as F is revolved the blocks C will recede from one another, so, at first, slightly raising the boat and then lowering it. At the same time, by means of the toggles M^1, the sleeve K will have been sufficiently moved to withdraw the end L^1 of L, so releasing the joint in the rods J, and allowing the side supports to fall as shown in dotted lines (Fig. 1). Six claims are made.—No. 16705. October 21st, 1890. 8*d*.



Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED BRASS FINISHERS' TURRET LATHE.

CONSTRUCTED BY THE NORTHERN ENGINEERING COMPANY, LIMITED, HALIFAX.

(*For description see page* 221.)

GENERAL VIEW.

THE ROYAL NAVAL EXHIBITION.

FOLLOWING the Military Exhibition of last year, the naval side of our defence is to have an Exhibition on the same grounds, adjoining the Royal Hospital, Chelsea. This Exhibition promises to be more successful than even the Military Exhibition.

What Chelsea Hospital is to the military service, Greenwich Hospital is to the naval service, and it was, therefore, proposed at one time that the present Exhibition should be held at Greenwich, amidst the associations of the service, the Naval School, and the fine museum of nautical models. But upon mature consideration it was considered that the difficulties of access were too great for a numerous collection of visitors to ensure the commercial success of the Exhibition. The limitation of space was another reason why it was not deemed prudent to hold the show there. As it is, in the present grounds, which comprise eight acres in addition to that covered by the late Military Exhibition, the committee have no difficulty in filling the whole area; the number of applications for space is so great that the difficulty is to make a judicious selection of the objects offered. As at present arranged, it is proposed to open the Exhibition on the 2nd May next.

The amended plan, given on page 218, gives an outline of the space covered, the additional eight acres being on the right from the arena to the boundary. On this new part an army of workmen is busily engaged in building the new erections and in making the alterations and additions required. Before describing these it will be well to advert to the objects of the Exhibition.

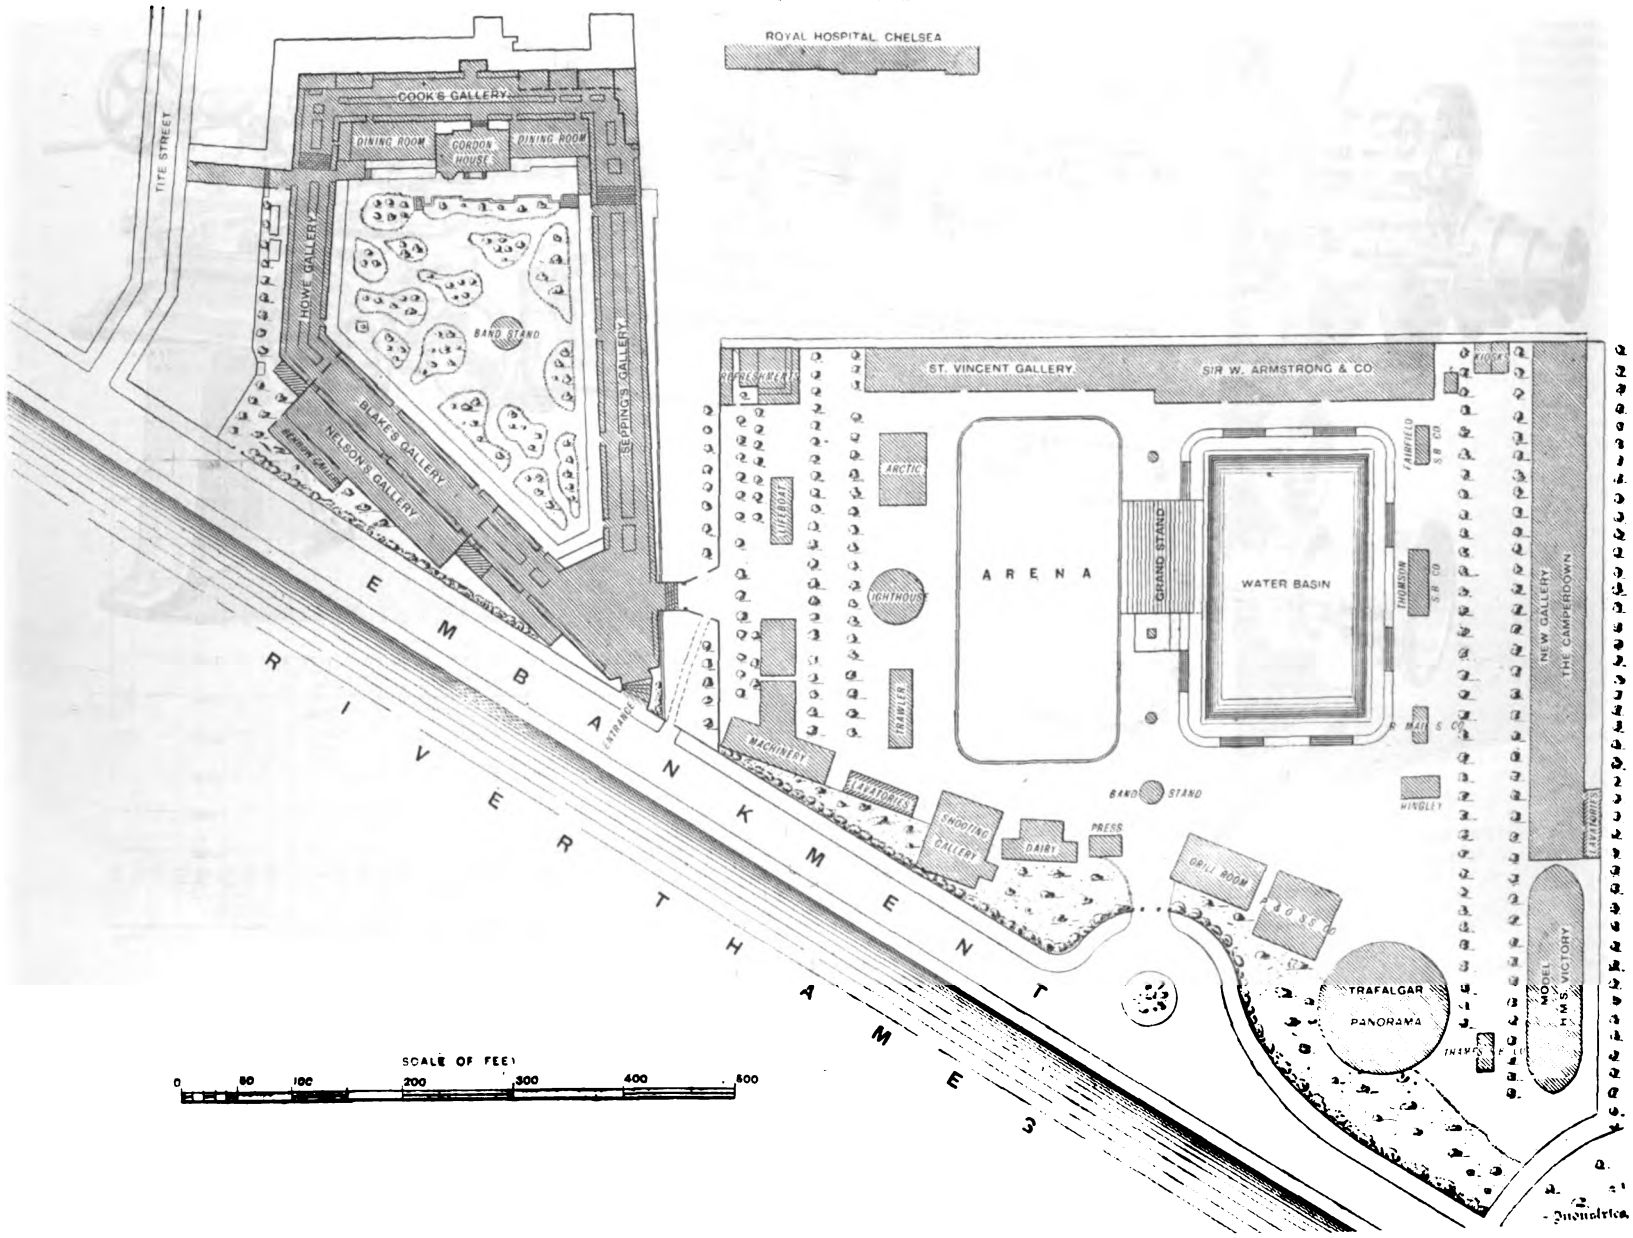
Although the Navy is recognised as our principal weapon of defence, yet from its very nature it is impossible for the great mass of the nation to form any idea from external evidence of the character of the service in which they are so deeply interested. It was considered, therefore, that an Exhibition which should convey to the general observer some conception of the rise and progress of the Navy, and the general character of our latest warlike productions, would be not only interesting, but productive of benefit, by creating additional popular interest in the service. Of course the Admiralty could not officially undertake the Exhibition, but a large number of volunteers from all branches of the service are entering with zeal into the duties on the various committees. Although it is anticipated that the receipts from the Exhibition will considerably exceed the outlay, it was considered prudent to procure a substantial guarantee fund, and thus relieve all connected with it from pecuniary liability, and at the same time to enlist the widest possible interest in the success of the undertaking. A large guarantee fund of £50,000 has therefore been raised from about 200 guarantors, many of our leading manufacturers giving their names for large sums. A great feature of the Exhibition will be its historical side. A collection of models and objects of interest will be brought together from Her Majesty's Dockyards, the Royal Naval College at Greenwich, and various other places, and these will admirably illustrate the naval history of the nation. The Arts Section will be represented by a most interesting collection of naval portraits, battle pieces, and relics. The buildings handed over by the Military Exhibition have been re-arranged and enlarged. Considerable additions have been made to the picture gallery; and the entrance, which is on the Thames Embankment, has been opened out and made more imposing.

About 300 applications for space have already been sent in, and from the list we find that all the leading builders of ships and manufacturers of marine appliances will be represented. Thus the Exhibition will be even more general in its character than its title indicates; it will be a veritable maritime exhibition. The collection of models will be probably the finest ever brought together. Not only will there be a complete series of historical models, but this will be supplemented by models contributed by all the most eminent shipbuilding and engineering firms in the country. Probably one of the most striking sets of models, and the highest in an educational sense to the tax-payers of the country, will be a complete series of models of the whole of Her Majesty's Navy at each particular station. Thus there will be the ships comprising the Channel Fleet, placed in position in the English Channel; another set will be the Mediterranean squadron, shown in the sea in question; other sections of the Navy will be given in conjunction with the particular parts of Greater Britain they are considered to protect.

A full-size model of Nelson's ship, "Victory," is now being built, as shown on the bottom right hand corner of the plan. The water line of the ship will be represented by the ground line, and the interior and lower deck will be made as realistic as possible to bring home to the minds of the visitors the appearance of the "Victory" on the day of the great battle of Trafalgar. Adjoining this model is being erected a panorama of the battle of Trafalgar. Contrasted with the model of the "Victory" will be the exhibit of Sir W. Armstrong & Co., in the St. Vincent Gallery. This will be a model, 270ft. long, of a modern armour-clad ship, with revolving turret guns and hydraulic loading gear complete, so as to show the latest improvements in the fitting and working of modern naval guns in a line-of-battle ship. Sir W. Armstrong's firm will also have a good display of ordnance and other material representing nineteenth century practice.

We may remark here that the collection of ordnance will be very complete. Service ordnance and gunnery and torpedo appliances have been supplied by the Admiralty, and these exhibits have been supplemented by all the famous gunmakers in the country. To illustrate the use of the Maxim, Nordenfeldt, and machine guns, a special gallery is being erected for exhibiting the firing of these guns. The section referring to navigation will be illustrated by a very complete and historical collection of objects connected with navigation. Amongst these we noticed in course of erection the model of the Eddystone Lighthouse. This model lighthouse is 155ft. high, and various types of electric lamps will be exhibited from the top.

In the new part of the grounds excavations are being made for a sheet of water 250ft. by 150ft., in which will be displayed nautical combats and other spectacles, the launching and firing of model torpedoes, and all that can be done on a miniature scale. This water basin will, no doubt, be a popular feature. The large new gallery, "The Camperdown," 450ft. by 50ft., already has the framework up, and is rapidly being covered in.



Amongst the miscellaneous sections are the Arctic section, the trawler and deep sea fishery, the lifeboat

THE ROYAL NAVAL EXHIBITION.

Amended General Plan.

(*For description see page* 217.)

and life-saving apparatus, and the diving bell and other diving appliances. The first of these three is under the direction of a branch of the Navigation Committee, and contributes a very interesting exhibit, illustrating Polar exploration and the conditions of life under the Arctic Circle, the whole being brought vividly home by a realistic miniature Polar Sea. Diving operations will be illustrated in a large glass tank under the eyes of the spectators, and is expected to constitute as great an attraction as formerly at the Polytechnic.

The arrangements for lighting the Exhibition have been entrusted to Messrs. Siemens Brothers & Co., whilst Messrs. Willans & Robinson and Messrs. Davey, Paxman, & Co. will supply the electric fittings, dynamos, and engines respectively. Seventeen hundred incandescent lights and 400 arc lights have already been arranged for. The dynamos will be the same as those in use in the navy, and of the latest noiseless type.

Under legal advice, and for the purposes of convenient working, the Exhibition has been formed into a limited company. Besides the numerous metropolitan committees, local committees under the chairmanship of the naval commanders-in-chief have been formed at the several naval ports, to lessen the labours of the London committees and to collect and arrange the materials that will be exhibited from the great naval centres of Portsmouth, Devonport, and Sheerness.

The financial arrangements are under a finance committee, which maintains a careful watch upon all items of expenditure. Should a surplus result, as anticipated, it is proposed to devote it to naval charities.

The amusements are somewhat out of our province to discuss, but the financial success of the Exhibition will largely depend upon the popularity of the entertainments provided. Messrs. Pain & Sons will illuminate the grounds with 10,000 coloured lamps every evening. Once a week arrangements will be made for a grand "pyrotechnical display" of a nautical character. Balloon ascents will also be a feature in the programme. By the permission of the Board of Admiralty, parties of bluejackets will attend from the naval ports, and will give exhibitions of field gun, cutlass and small arm, and other drills.

THE SOCIETY OF ENGINEERS.

At a meeting of this Society, held on the 2nd inst., Mr. W. N. Colam (President) being in the chair, a paper was read by Mr. Arthur Rigg, on "The Balancing of High Speed Steam Engines." The author said that this paper formed the continuation and completion of one read by him before the Society of Engineers on the 5th April, 1886, entitled "Obscure Influences of Reciprocation in High Speed Engines." The earlier paper dealt with the internal strains caused by reciprocation, and the means by which their incidence on the engine itself could be rendered less violent, and the present paper was intended to take note of the external effect of these strains, and the modes by which their vibratory influence might be counteracted in a greater or less degree. The paper commenced with a memorandum on the origin and measurement of these strains, and this introduction was followed by a description of the effect of a balance weight opposite the crank, and the different influence of such a balance on horizontal or vertical engines. Then followed a consideration of the modes by which rapidly recurring strains are met and counterbalanced by the action of two engines with opposite cranks, and the effect of the air buffer in Mr. Willan's engine. This part of the paper was illustrated by curves showing the correspondence between the air compression and inertia diagrams, and the strains absorbed and those transmitted to the foundation were duly considered.

A comparison was made between the effects of a compression of exhaust and an independent air buffer, showing how the former entailed a permanent loss of useful effect, which in some measure aided in producing the economy desired by an independent method for bringing the reciprocating parts to a state of rest. The final subject touched upon related to the balancing of revolving cylinder engines where pistons and cylinders alike turned round upon their own independent centres, whereby a complete dynamic balance was secured so far as reciprocation was concerned, but replaced by a series of variations in angular velocity which, although influencing the true balance, did not appear outside the engine. The author remarked that this system transferred the limited speed of engines from dynamic relationships of their reciprocating parts to considerations of centrifugal force, and the best velocity of inlet and efflux of steam through the ports and passages, and marked a distinct advance; and although those of the present time might be of most immediate interest, yet it was well to remember systems of balancing which possessed features of interest in the past, and to pay some attention to those changes which the future might have in store.

IRREGULAR WEAR OF LOCOMOTIVE TYRES.*

THE tendency of locomotive tyres to wear irregularly—that is, to form flat places, or to wear the tread out of its original cylindrical form, concentric with the journal—is one of the most annoying and expensive of the minor trials to which a railroad master mechanic is subjected. This trouble is aggravated when roads pass through sandy districts. At first sight the most natural conclusion is that the tyre varies in hardness, or resistance to abrasion, and this undoubtedly is the cause of a portion of the trouble, but from an extended series of observations the writer is compelled to conclude that a material portion of the trouble lies outside the tyre itself. This conclusion has been arrived at from the following observations:—

First—The tyre of several locomotives showing serious flat places have been slipped around on the centre, then trued up and placed in service. The flat places in every case formed again at the same place relative to the centre, but in a different place on the tyre.

Second—Observations made on a large number of tyres running in a sandy district showed that the flat places grouped themselves with a close approach to uniformity, occupying nearly the same position with reference to the pins and counterbalance.

The above clearly indicates that there are cases of irregularity in the wear of tyre due to the forces which are in action in operating the locomotive, and it is the purpose of this investigation to partially determine the nature, extent, and influence of these forces.

For this purpose engine 316 was taken, the dimensions bearing on the question being as follows:—

Diameter of cylinder, 16in.
Stroke of piston, 24in.
Diameter of drivers, 62in.
Total weight on drivers, 54,000lb.
Boiler pressure, 160lb.
Cylinder pressure, 130lb.
Cut-off, 6in.
Speed per hour, 40 miles.
Weight of reciprocating parts, each side, 480lb.
Weight of main rods, 269lb.
Weight of main rod taken as reciprocating, 117lb.

The total weight of reciprocating parts was counterbalanced, the counterbalance being equally divided between the wheels.

With the above data Table I. has been computed, showing the forces in action at each ten degrees of a revolution, the zero point being taken as that point at which the right-hand driving wheel pin passes the forward centre.

TABLE I.

FORCES IN ACTION ON ENGINE 316 MOVING AT 40 MILES PER HOUR.

340	15,049	19,408	14,813	17,105	66,375	17,390	·105
350	14,079	19,311	14,164	17,282	64,836	13,274	·081

This table shows in the first column the position of the wheel by degrees. The second, third, fourth, and fifth columns show the pressure of each wheel against the rail, with the engine moving at forty miles per hour. The pressure of the two back wheels varies from 9,660lb. to 17,340lb., or 3,840lb. above and below the static load of 13,500lb. This variation is due entirely to the influence of the contrifugal force of the counterbalance. The pressure of the two forward wheels is subjected to precisely

* Paper read by Mr. J. N. Barr at the January meeting of the American Western Railway Club. We are indebted to the *Railroad Gazette* for our illustrations.

IRON AND STEEL PRODUCTION IN THE UNITED STATES AND GREAT BRITAIN.

the same influence from the counterbalance, and in addition to this, the angularity of the connecting rod effects a decided modification of the pressure on the rail. The sixth column, headed "Total," shows the sum of the pressures of the four wheels upon the rail. The total pressure varies from 67,712lb. to 45,935lb., a difference of ten tons. The sixth column is represented graphically in Fig. 2. The seventh column shows the pressure against the pin normal to a line passing through the centres of pin and wheels, or the force at the pin tending to produce rotation. This column is represented graphically in Fig. 3. The rotative force at the rail can readily be deduced from these figures. The eighth column shows the relation between the forces producing pressure on the rail and the forces which have a tendency to cause the tyres to slip. The figures are obtained by dividing the force tending to slip the drivers, or the rotative force at the rail by the pressure on the rail. We will call this ratio the coefficient of slip. It corresponds in form and relation to what is known as the coefficient of friction. If the value of the coefficient of slip is equal to the coefficient of friction the wheels will be on the verge of slipping. Fig. 4 is a graphical representation of these values. The coefficient of friction between wheels and rails or the coefficient of adhesion is given by Haswell as follows:—

TABLE II.

COEFFICIENT OF ADHESION UPON DRIVING WHEELS.

Condition of Rail.	European Practice.	American Practice.
Rail very dry	·3	·33
Rail very wet	·27	·25
Ordinary condition	·2	·222
In misty weather	·15	·2
In frost and snow	·09	·16

These figures are obtained by dividing the horizontal force applied to the wheel at the rail, that is just sufficient to produce slipping, by the pressure of the wheel on the rail, and can be compared directly with the values given in the eighth column of Table I.

We will now proceed to apply the data given in Table I. to a case of wear taken from actual practice, and illustrated in Fig. 1. The wear is shown by full lines for the right-hand wheels, and dotted lines for the left-hand wheels. The depth of wear as shown is exaggerated to prevent confusion of lines, and shows just twice as great as the actual wear. On the forward wheels there are two flat places of about the same size in the same location. This varies from the general results, as in most cases the flat place on the right wheel is much less than that on the left wheel, and there seems good reason to believe that the flat place on the right-hand wheel has been modified by a soft place in the tyre. By referring to Table I. it will be seen that the coefficient of slip at 50 degrees is ·167, and that this exceeds the coefficient of adhesion for a frosty rail and that it approaches uncomfortably close to the coefficient of adhesion for ordinary condition of rail. The tendency to slip slightly, or to what is known as imperceptible slip, must be quite decided under these conditions. A corresponding flat place is found on the left back wheel, but the right back shows no flat place. Several cases show some wear on the right back wheel corresponding with that of the left back wheel, but always less in quantity, and in this case doubtless more careful measurement would have shown some wear. Considering the four flat places as shown in the neighbourhood of 80 degrees, why do they vary, always being greatest on the left-hand tyre? An inspection of the weight on rail seems to show the reason quite clearly. Table I. shows the pressure of the four wheels on the rail at 60 degrees to be as follows:—L. F., 15,979lb.; L. B., 15,420lb.; R. F., 12,539lb.; R. B., 10,559lb., and the average size of the flat places correspond with these pressures. There are two other flat places on these wheels, one on the right back at 200 degrees and one on the left forward at 310 degrees, which can scarcely be accounted for by slips, but are likely due to soft places in the tyre. As the speed of the engine increases the coefficient of slip is varied by the increased intensity of the action of the centrifugal force of the counterbalance. A change in steam pressure and cut-off also affect these values.

There is a possibility that further and closer observations, covering a sufficient number of cases to eliminate the question of variation in the hardness of the tyre, will develop the following:—Flat places will be found near the 60 degrees point, varying as shown above. Flat places will be found near the 140 degrees where the coefficient of slip reaches ·185, but much less than the preceding, on account of light total pressure on the rail and all nearly of the same size as the pressure of the wheels on the rail are all four nearly equal. Very slight flat places may also be found at the 220 degrees point and the 320 degrees point, which are two other maximum points of the coefficient of slip. It would appear from a comparison of the flat places with the weight on rail that when the pressure does not exceed 11,000lb. the tendency to abrasion from imperceptible slip is very slight. The conclusions to be drawn from the above may be summarised as follows:—

1. Flat places on driving wheel tyres are not entirely due to lack of uniformity in the wearing quality of the same.
2. The flat places have a tendency to group themselves where the coefficient of slip is greatest.
3. They vary in depth with the pressure on the rail, and when the pressure does not exceed 11,000lb. the imperceptible slip produces but little abrasion.
4. Imperceptible slip does not appear at random on any part of the wheel, but in special localities as fixed by the maximum values of the coefficient of slip.
5. The counterbalance should be as light as possible compared with the reciprocating parts, consistent with smooth riding.
6. The weight of the reciprocating parts should be as light as possible.

IRON AND STEEL PRODUCTION IN THE UNITED STATES AND GREAT BRITAIN.

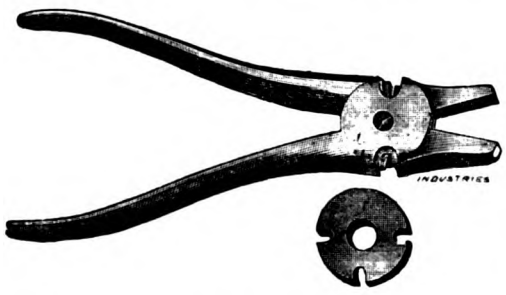
THE accompanying diagram, for which we are indebted to our American contemporary *The Iron Age*, shows at a glance the production of iron and steel in Great Britain and the United States for the last thirty years. The diagram requires little description, but we may here point out the enormously rapid increase in output of pig iron in the United States, which completely eclipsed that of Great Britain in 1889, although in 1887 the output of the latter was about 1,800,000 tons more than the former. In Bessemer steel, too, a similar feature is noticeable.

THE INSTITUTE OF MARINE ENGINEERS.

A MEETING of this Institute was held on the 24th ult., Mr. F. W. Wymer being in the chair, when a paper was read "On the Application of Zinc," by Mr. Green. The author proceeded to point out the different kinds of zinc for marine boilers and the various styles of application. The cast zinc, fitted in the most approved form, was described, and the advantages and disadvantages of rolled and cast zinc were indicated.

On the conclusion of the paper some remarks by Mr. David Phillips (whose name is well known in connection with the application of zinc to boilers) were read by Mr. Wilson, in the course of which the use of cast as opposed to rolled zinc was advocated. During the discussion which followed several drawings and a number of interesting specimens were shown. The meeting was adjourned till the 3rd inst.

Digitized by Google



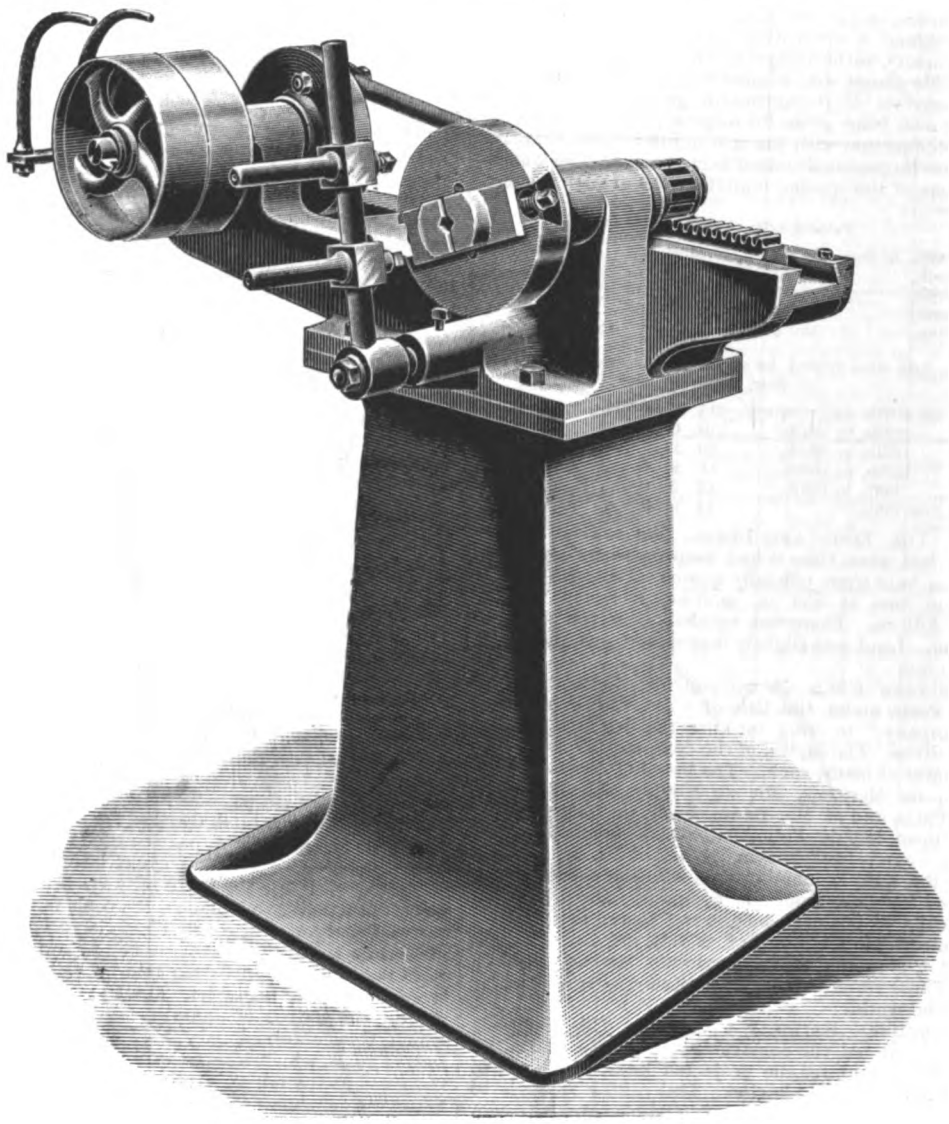
BRASS FINISHERS' PLUG GRINDING MACHINE AND TURRET LATHE.

THE machine shown in the annexed illustration is designed for expeditiously grinding the plugs of brass valves, &c., into their barrels. The plug is securely gripped in the jaws of the self-centreing chuck, which is revolved backwards and forwards by the connecting-rod attached to the driving disc, the workman meanwhile sliding the barrel between the adjustable forks upon the plug. In so doing he is able to detect (as in ordinary hand grinding) the presence of any foreign substance, and to remove it without delay. This machine is made in two sizes by the Northern Engineering Company, Limited, Halifax. In the larger machine an arrangement for holding heavy castings is fitted, consisting of a bracket and special slides with "gripping dogs." This enables the machine to be used upon a wide range of work. As will be seen from the engraving, the machine is self-contained, and is supported upon a strong cast-iron pedestal.

The same firm make a brass finishers' turret lathe. This lathe is shown on page 217, and is in many respects similar to those used in American brass finishing establishments. The bed is arranged with a cabinet with shelf for holding loose tools. The fast headstock is double geared, and the spindle has a hole through it. The loose headstock is arranged to rotate through an angle of sixty degrees, and is mounted upon a transverse traverse slide; it is also fitted with an internal and external shoot, and with lever motion for use in work which the turret tools cannot reach. The saddle is fitted with self-acting sliding motion by cones and shaft along the front of the bed, with instantaneous starting and release motion, also with quick hand traverse. The turret rest is arranged to carry six tools, and is mounted on compound slides with a swivelling arrangement indexed for taper work. The top slide is fitted with lever motion as well as screw, which is of great advantage in getting work out quickly. The chasing rest is fixed to a shaft at back of bed; keyed on to the end of this shaft is an arm, which carries a die. When the chasing rest is brought over on to the bed of the lathe, this die comes into gear with the copying screw, which is worked from the fast head spindle wheels, and the chasing tool is carried along the bed, the thread on the copying screw being reproduced on the article chucked in the lathe. When the chasing apparatus is not in use, it is lifted back again, and when resting on the backboard is clear of the turret slides. An arrangement can also be fitted for taper chasing.

THE "ACME" PLIERS.

THE accompanying engraving represents pliers made by the Higganum Hardware Company, of Higganum, Con., U.S.A., and particularly intended for linemen and others engaged in electrical construction. As will be



seen, the pliers combine a wire shears, the cutters of which are renewable, so that when one wears out it can be replaced at small expense and with little trouble. The illustration is taken from our American contemporary, the *Electrical Engineer*.

DECIMAL COINAGE, WEIGHTS, AND MEASURES.

A PAPER on the above subject was recently read by Mr. J. Emerson Dowson, M.Inst.C.E., at the Society of Arts, Sir Henry E. Roscoe, M.P., F.R.S., being in the chair. The author said that several public inquiries had been held, but none since 1862. In these inquiries an immense amount of valuable information was got together, but no Committee or Commission was instructed to deal with the subject of coins, weights, and measures as a whole, or to consider the intimate relations of one to the other. It would be Utopian to suppose that all must be changed at once, but the subject should be thoroughly investigated in its broadest and most detailed aspect. At the present time a decimal system of coinage had been adopted by every civilised country except Great Britain and some of her dependencies, and a large coloured map of the world was exhibited, which emphasised this fact in a striking manner. If the values of our coins, weights, and measures were founded on decimal relations, and on the same basis as our present system of notation, whole numbers and fractions could be added, subtracted, multiplied, and divided by the rules of simple arithmetic, and compound arithmetic would be entirely superseded. In the Board Schools, for instance, at least two years' teaching of arithmetic was now taken up by subjects which a decimal system would render wholly unnecessary. In the elementary schools of Belgium and France nothing was more impressive than the great simplicity of their arithmetic, compared with ours. Great as was the need for a decimal system of coinage, it was even more important that our present unsystematised weights and measures should be simplified and decimalised. During the last twenty years especially all the leading European countries had enormously increased their powers of production, and they were not only striving to manufacture all required for their home consumption, but were energetically pushing the sale of their wares in other countries. English engineers and manufacturers were in fact in keen competition with those of other countries, and our Consuls had in several instances drawn attention to the loss of trade we sustained owing to the difficulty foreign dealers experienced in understanding our language, our coinage, and our weights and measures. Several points of interest and importance were referred to, and from recently published Board of Trade statistics it appeared that in 1889, excluding British possessions, the value of the imports to and exports from foreign countries using the metric system was £348,862,574, or about 62½ per cent. of the total imports and exports. The adoption of the metric system had spread considerably, and would certainly continue to spread. India had prepared the way for adopting it, and it was probable that if it were adopted here it would also be taken up in Australia, Canada, and our other dependencies. There was a probability also that the United States and Russia would sooner or later adopt the metric system, and then there would be a uniform system of weights and measures throughout the civilised world. Apart from this, we were directly interested in doing away with our absurd weights and measures, and in simplifying our arithmetic. Other points of detail were discussed, and, in conclusion, the lecturer urged the pressing need of a Royal Commission to thorougly investigate the whole subject in the light of our present requirements. The seventy-two Associated Chambers of Commerce were all in favour of a decimal system, as well as the important Chambers of Glasgow, Edinburgh, Liverpool, and Manchester.

BRASS FINISHERS' PLUG GRINDING MACHINE.

CONSTRUCTED BY THE NORTHERN ENGINEERING COMPANY, LIMITED, HALIFAX.

GENERAL VIEW.

IRON MANUFACTURE IN NEW ZEALAND.

A NEW ZEALAND report states that it will be possible to produce pig iron there as cheaply as at home. Coal, iron ore, and limestone exist at Kamo, near Wangarei, and it is intended to erect a blast furnace there for the manufacture of pig iron. The estimated cost of production is £2 8s. 3d. per ton.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 3rd March, 1891.

Iron.—There was a little more animation in the iron trade last week. Orders came in fairly, but prices continued low; bars were easily obtained, if the order were of any importance, for 125s., and joists for 133s. a ton. Castings were quoted at 112s. 6d., sheets at 156s. 6d., and old rails at from 70s. to 72s. the ton. The Minister of Public Works has signed a convention passed with the Orleans Railway Company, authorising the construction of 267 kilometres of wide gauge, 410 kilometres of one metre gauge, and 53 kilometres of 70-centimetre gauge lines. Some orders have also been given for narrow gauge railways for Tonquin in connection with the coal mines of that country. In the Haute-Marne the situation is improving. The quotations for some of the special manufactures of this district are as follow:—

Turned axles of from

100lb. to 140lb.,	in iron	£11	5	0,	in steel	£14	1	0 the ton.
70lb. to 98lb.	,,	11	13	0	,,	14	9	3 ,,
50lb. to 68lb.	,,	13	5	0	,,	16	1	6 ,,
30lb. to 48lb.	,,	15	5	0	,,	18	1	6 ,,
20lb. to 29lb.	,,	20	1	6	,,	22	18	0 ,,

Welded tyres, with holes drilled for all kinds of vehicles, sold by the pair,

From 402lb. and upwards,	£11	13	0 the ton.
,, 222lb. to 400lb.	10	0	9 ,,
,, 162lb. to 220lb.	10	9	0 ,,
122lb. to 160lb.	11	9	0 ,,
,, 80lb. to 120lb.	12	9	0 ,,
Below 80lb.	14	9	3 ,,

Copper, Tin, Zinc, and Lead.—The copper market was firmer last week than it had been for some time past. Best Chilian bars were officially quoted at £58 15s., ordinary Chilian bars at £56 5s., and best selected Chilian copper at £61 5s. There was no change in the prices of tin and zinc. Lead was slightly dearer, and was quoted at £13 7s. the ton.

De Meritens' Cell.—A company has been recently formed in Paris, under the title of "The Industrial Electricity Company," to bring into use the cell invented by Mr. de Meritens. The capital of the company is 4,000,000fr. in 8,000 shares of 500fr. each. The board of directors consist of Mr. de Meritens, Mr. de Monteynard, Mr. de la Hante, at Paris, and of Mr. Baranoff, Mr. de Baschmahoff, Mr. de Keppen, Mr. de Potenkim, Mr. de Semkoff, at St. Petersburg. As is well known, the cell of Mr. de Meritens resembles the auto-accumulator of Mr. Jablochkoff, who has received 50,000fr. from the company. One of Mr. de Meriten's cells, of 20cm. in height and 15mm. in diameter, gave an electromotive force of ·8 volt, or ·4 volt with a current of 2 amperes at its maximum output—that is, ·8 watt. These results are scarcely likely to revolutionise the industrial world.

The Northern Railway Company.—This company has recently ordered the construction, at a cost of £3,360, of some rolling stock for the projected lines, which run to the Halles and to the Madeleine. This rolling stock is to be constructed in the company's workshops, and will consist of three six-wheeled carriages and two baggage waggons. Each carriage will be 23 metres in length, and is specially designed to travel on curves of small radius.

Tunnel under the Seine.—A project for a tunnel on the line of railway from Havre to Port Andemer is under consideration. It is to consist of a cast-iron tube traversing the alluvial stratum under the river for a distance of two kilometres and a half; the remaining portion, which runs through a chalk formation for a length of two kilometres, will be in masonry. The whole of this tunnel, of four and a half kilometres, is designed by M. Berlier, an engineer whose name is also connected with a scheme for laying tramways under Paris in metallic tubes.

BERLIN, 2nd March, 1891.

Condition of Trade.—Trade in general has not been so brisk in Berlin this year as last year, and a large number of workmen have been without employment during January and February. The long winter, which has continued with hardly any interruption since November, has brought the building trade almost to a standstill, and in consequence of this the demand for iron goods for buildings has been greatly reduced. The building trade is a very important feature of Berlin industry, as will be seen from the fact that since 1870 the population of Berlin has doubled itself, and is now 1,600,000. The canals which connect Berlin with the seaports are now free of ice, and traffic upon them is being resumed. The Berlin market is thus opened for English pig iron, and a slight impulse in the trade will probably make itself felt. Although the waterways in connection with Berlin are small, and generally used only by slow barges, they are of great importance to Berlin. The amount of goods brought to Berlin by water is greater than that brought by rail, and the re-opening of the waterways after the winter is therefore generally attended with an improvement in trade.

Railways.—The work in connection with additional lines of rails between here and Potsdam *viâ* Wannsee is being pushed forward as rapidly as possible, and it is hoped to have a third and fourth line of rails completed by October. The Potsdam station is being considerably enlarged, and when all is finished there will be a frequent service upon the new lines similar to that of the metropolitan railways. The "Ringbahn," the line which goes round Berlin, is being widened in several places, and some stations are being enlarged.

Telephones.—The employment of female operatives in the telephone offices having been found so satisfactory it has been decided to appoint only women for these posts in future. The telephone is extensively used in Berlin. There are over 12,000 telephones here, not including private installations.

Government Factories at Spandau.—Several hundred workpeople have been discharged from the Government factories, and further reductions are expected.

Petroleum in Germany.—The German Petroleum Company, whose operations have been hitherto confined to Oelheim (Hanover), have commenced work at Hagenau (Alsace), where they hope to meet with very good results.

Rolling Stock of the Prussian Railways.—During the past two years the rolling stock has been increased by 801 engines, 1,240 railway carriages, and 17,684 luggage and goods waggons. At the present time the rolling stock of the Prussian State Railways consists of 9,653 engines, 15,343 passenger carriages, and 196,798 luggage and goods vans.

VIENNA, 2nd March, 1891.

The Iron Market.—Business in most sorts of iron has somewhat increased, but prices remain unchanged. It is expected that the struggle with the German iron works will be followed by measures to prevent an increase of prices. In Hungary trade has been dull. Pig iron was largely offered for sale, and producers were willing to make concessions in the case of sales for some months in advance. These offers, however, remained without effect, and purchasers bought only for present needs.—The Hungarian Government is about to erect a new waggon manufactory. The machine works of the State railways are to be considerably enlarged, so as to permit of the manufacture of 309 waggons a year. At a general meeting of the "Nadrager Iron Industrial Company," which was on the point of being dissolved, it was decided to prolong the existence of the company in view of the present state of the iron industry. The Budapest City Railway Company announce a dividend of 10 per cent.

The Coal Market.—Notwithstanding the favourable weather there is a brisk demand for coals, both for industrial and for household purposes. It is to be regretted that the needs of this important branch of industry are neglected both by the State railways and by private railways. Whenever the demand for coals is very brisk, there is a deficiency of waggons. There is still a want of coals in Vienna owing to the stagnation of traffic a month ago. Both the Silesian and Ostrau coal mines are suffering from the difficulties of transport. The Upper Silesian coal mines during the month of January needed 4,755 waggons, of which they obtained only 3,377 waggons, so that 14,000 tons of coals, which were to have been forwarded to Vienna, remained at the mines. At the Northern railway and Ostrau mines the deficiency of waggons, as far as can be ascertained, is greater than in Silesia. It is to be hoped that this state of affairs will soon be remedied by considerable additions to the rolling stock.

BRUSSELS, 3rd March, 1891.

The Metal Market.—The situation continues to improve. Orders are more plentiful, and though prices are still unsatisfactory, business is becoming brisker everywhere. Many rolling mills in the districts of Liège and Charleroi have orders for more than two months in advance. Big joists are also in somewhat better demand. Pig iron is firmer. Before manufactured iron could recover its normal value, coal and pig iron increased in price. Some large orders for rails and angle iron for export have been received: 20,000 tons of rails for Brazil, by Messrs. Cockerell; 8,000 tons for Brazil, by Messrs. Cockerill, Angleur, & Ougreé; 3,000 tons of bridges by the workshops of Braisse-le-Comte; a large order for delivery to Greece, and some trollies for the State Railway, by a workshop of Boon. The situation, however, would be further improved if the Government would reduce the cost of transport. Ironmasters and owners of coal mines have already petitioned for these reductions, which are rendered still more desirable by the present condition of affairs.

The Coal Market.—The condition of the market continues favourable. For industrial sorts no concessions are made on orders for present delivery, but a reduction of 2fr. is made for future sales. There is a demand for coal from several quarters, which, from the condition of the iron industry some time ago, was not considered probable. An excellent trade in bricks and limestone is expected, and this renders the prospect still better. This favourable condition of affairs is to some extent darkened by strikes which are taking place in certain parts of the country, and among other places at Marihaye. Coke remains firm at 18fr., small sorts at 12fr., furnace coal at 14fr., and boiler coal at 12fr. The relighting of the coke furnaces at Liège, and at the coal mines of Horloz and de la Haye, is thought probable. The object of this would be to utilise the sorts of coal which are suitable for the production of coke, but which are not useful for domestic purposes.

Commercial Treaty between France and Belgium.—The present commercial treaty contains two kinds of clauses, the one showing the Customs duties to which goods imported from one into the other of the two contracting countries are subject, and the second set of clauses relating to questions of transit and regulations as to commercial travellers. The French Government has proposed to the Belgian Government the renewal of these latter clauses, but wishes to maintain its liberty of action as regards the question of Customs duties.

DÜSSELDORF, 3rd March, 1891.

The Iron Market.—The condition of the pig iron market is rather unsatisfactory, since new orders are scarce. The stocks at the blast furnaces were as follow:—

	Dec. 31st, 1890.	Jan. 31st, 1891.
Best puddled iron, including spiegeleisen...	36,649 tons ...	39,551 tons
Ordinary puddled iron	8,050 ,, ...	6,498 ,,
Bessemer iron	13,868 ,, ...	12,297 ,,
Thomas iron.....	29,713 ,, ...	29,722 ,,
Total.....	88,280 tons ...	88,068 tons

The stocks of foundry pig iron at the blast furnaces amounted to 24,245 tons on January 31st, 1891, against 23,736 tons on December 31st, 1890. The rolling mills are briskly employed in the execution of outstanding orders. The business of the foundries and machine works is, with few exceptions, satisfactory. The market for coarse and fine sheets is unaltered.

Chromium and Nickel Mines.—A chromium mine has been recently opened in Silesia. This discovery is of great importance, as the inland industries have hitherto been dependent on foreign supplies. The nickel ore discovered in the neighbourhood of Frankenstein is estimated at many hundred thousand tons. According to the analysis the ore contains up to 17 per cent. of nickel, and the average is from 2 to 3 per cent.

Cement Manufactory.—A limited company has been formed in Halle, with a capital of 1,400,000 marks, to establish a large cement factory.

General Engineering. — The Königsberger-Maschinenfabrik has undertaken the construction of waterworks at Scutari and Kadikui, at an estimated cost of three million francs. All the necessary engines, boilers, and pumps will be sent out from the company's works.

Difficulties of Transport.—Although the deficiency of railway waggons has almost ceased to be felt, the coal industry still suffers from the consequences of the previous stoppage of traffic. The mines in this district have begun to limit their output, since the present prices scarcely cover the cost of production.

AMSTERDAM, 2nd March, 1891.

Shipping at Rotterdam.—The Rotterdam Chamber of Commerce has published (in English) an extract from the registers kept at the harbour offices during the year 1890, showing the movements of ships during last year compared with previous years. The number of vessels cleared inwards through the new waterway—excluding 2,210 fishing vessels and 55 foreign tug-boats entered in 1890—was as follows:—

	1887.	1888.	1889.	1890.
Steamers and sailing vessels...	4,114	4,490	4,484	4,482

The tonnage entered was as follows:—

1887.		1888.		1889.		1890.
3,509,292	...	3,829,721	...	4,026,446	...	4,274,854

It will be observed that although the number of vessels cleared inwards was lower in 1889 and 1890, the aggregate tonnage shows an increase all through. This is, of course, owing to the fact that the vessels making use of Rotterdam as a port are every year larger on an average. The biggest ships cleared inwards in 1890 were steamers from Odessa, the "Rector" from that port having a draught of 24ft. 10in.

The Blitong Tin Company.—The Minister for the Colonies has stated in the First Chamber that the negotiations between the Dutch Government and the Blitong Tin Company, concerning the renewal of the concession, have been resumed, and promise an early result.

Utilisation of Waste Lands and Heaths.—The Dutch Society for the Promotion of Industry has appointed a committee to study the question of the utilisation of waste lands and heaths in Holland, with special reference to the point whether the utilisation should be made a governmental task or be left to private effort.

New Industrial Company.—The Queen of Holland has approved the articles of association of the Dutch Phosphate Company, formed with a capital of 2,000,000 guilders, to work phosphate properties in America and Europe.

Steamships in the Dutch East Indies.—The nine steamers which belonged to the English company that had the contract for carrying the mails between the islands of the Indian archipelago have been sold to a syndicate at Singapore, owing to the transfer of the said agreement to a Dutch company. The intention of the buyers is to organise with them a local steamship service, mainly along the coasts of Java.

Digitized by Google

STOCKHOLM, 28th February, 1891.

International Telephones.—The Swedish Parliament has voted a sum of 60,000kr. for a telephone from Orebro to the Norwegian frontier at Magnor, subject to the Norwegian Government finding the money for a telephone line from there to Christiania.

New Swedish Man-of-War.—The Government has approved of the drawings for a new warship similar to the "Svea," with the difference of a ram being placed at the bows of this new ship instead of a mine tube, if this alteration should not make the cost exceed the estimate of 2,290,000kr. Tenders are to be invited for the vessel and for its engines, both from home and foreign firms. The new ship is to be ready for trial by the end of March, 1893.

Alteration of Military Rifles.—At the Carl Gustaf Rifle Manufactory the alteration of the old infantry rifles to the 1889 model is now being actively carried on. The alterations are being made with the view of adapting the rifles for a smokeless powder.

Industrial Meeting at Gothenburg.—In connection with the approaching Exhibition at Gothenburg, to be held during the summer, there will be a general meeting of representatives of all Swedish industries. The dates fixed for this meeting will be the 19th, 20th, and 21st of August.

Proposed Finnish Railway to Tornea.—A proposal has been introduced into the Finnish Landtdag urging the building of a railway from Uleaborg to Tornea. In the event of the Lulea-Ofoten railway being carried through to the Norwegian coast, and the Swedish State railways being extended to the Finnish frontier, Finland would thus obtain direct railway communication with an ice-free port on the west coast of Norway, and also be brought into direct connection with the Swedish State railways.

CHRISTIANIA, 28th February, 1891.

Timber Cutting.—The cutting of timber in the Frederikshold district will this year be considerably reduced, the low prices for timber abroad and the large stocks in all the shipping ports, making a reduction necessary. Prices are not likely to increase until the production has been lessened.

New Steamer.—The steamer "Snorre Sturlason," intended for whaling at Iceland, was launched from the Aker Engineering and Shipbuilding Company on the 23rd inst. The steamer "Transport I." had a satisfactory trial trip on the 21st inst.

Kongsberg Silver Works.—According to estimates for the approaching financial year the expenses at the Kongsberg Silver Works will be 666,000kr., and the receipts 568,000kr., leaving a deficiency of 98,000kr. This unsatisfactory result is owing partly to heavy expenses for the extension of old mines and partly to the output of pure silver having been estimated at only 4,500kgr., although as much as 6,000kgr. have been obtained in previous years.

Guano Manufactory.—A new guano manufactory is being erected at Aalesund, and will be completed during next summer. The Brekke combined drying and grinding appliance will be used. This apparatus can be used for the treatment of all kinds of fish, and produces guano in five or six hours. There is a saving of time and labour by the use of this process, and a better and more uniform product is obtained.

New Gunboat.—It is proposed to increase the Norwegian Navy by the building of one new gunboat during the present year. It is to carry one 21-centimetre breech-loading gun with shield, one 7-centimetre and one 5-centimetre rapid-firing gun. There will be a 4-centimetre armoured deck, and an armoured tower with 10-centimetre armour. Cellulose will also be used for protective purposes. The gunboat "Viking," which is in course of construction, will probably be launched this spring.

ZURICH, 3rd March, 1891.

Swiss Watch Manufacture.—Notwithstanding the severe competition of foreign countries, the watchmaking industry in Switzerland continues to make good progress. The following table, compiled from the statistics of 1890, just published, gives a comparison of the exports during the last three years:—

	1888.		1889.		1890.	
Gold watches, chronographs, &c.	29·9	...	35·9	...	38·3	millions.
Silver watches	33·3	...	39·5	...	41·7	,,
Watches made of nickel, &c., and pedometers	12·2	...	13·2	...	13·8	,,
Watch movements, fittings, and cases	6·5	...	8·5	...	8·8	,,
Watches, total	81·9	...	97·1	...	102·6	,,
Clocks, including the necessary fittings	0·1	...	0·1	...	0·1	,,
Musical bells and boxes	3·0	...	3·1	...	3·3	,,
Grand total	85·0	...	100·3	...	106·0	millions.

International Exhibition of Scholastic Geography at Berne in 1891.—Under the auspices of the "Bureau du Congrès International de Géographie," an International Exhibition of objects appertaining to scholastic geography is being organised at Berne. This Exhibition which will be open from the 1st to the 15th August next, will comprise the following sections:—(1) Instruction books; 2) the means of instruction by intuition; (3) programmes of actual geographical instruction; (4) work done by students.

MADRID, 2nd March, 1891.

The Price of Coke at Madrid.—It will perhaps excite the envy of English gas companies to hear that whilst Spanish gas coals cost about 30s. per ton at Madrid, gas coke is sold at the high price of 66s. per ton. From this sum 7s. 6d. must be deducted for excise duty and cost of distribution, and the gas works receive the remaining 58s. 6d. Since the consumption of gas coke is large, and that of gas is comparatively small, gas coke is imported from distant towns, and even from England. It is difficult to explain why coke is not made in some of the Spanish coal districts, as an excellent quality of coke could be made and sold in Madrid at about 34s. per ton.

Railway Amalgamation.—Soon after the formation of the company called the Great Central System of Spain, which is supposed to interfere with the traffic of the Northern system, another important amalgamation of lines is announced. This will consist of about 6,000 kilometres, or nearly 3,750 miles, and will thus be one of the largest in Europe. It will include the present system of the North of Spain lines, the lines from Tarragona and Barcelona to the French frontier, and the line from Barcelona to the coal basin of San Juan de las Abadesas. The principal change effected by this amalgamation is that the new company will be administered entirely in Spain, the head offices being at Barcelona, where many of the shares of these lines are held. The new company will probably buy all their plant, rails, and rolling stock from Spanish manufacturers. The Northern Railway hopes, by the formation of this company, to avoid the loss of traffic which the Great Central System would otherwise cause to its lines.

The Use of Lifts in Madrid.—Lifts are being extensively erected in private houses in Madrid. Messrs. Samain, a French firm, are competing with a local firm, and their lifts are of better construction and cheaper. There is room for an English firm to compete, as several hundred lifts will be required during the next few years. The price generally quoted for lifts for four-storied houses is £600, but this depends somewhat on the situation as regards water power.

ROME, March 2nd, 1891.

New Form of Dry Cell.—Messrs. Dalle Molle & Co., of Ancona, have lately succeeded in producing an economical and satisfactory dry cell, seven of which are stated to have the same power as ten Leclanché cells with sal-ammoniac, which are now largely used in this country. Dry cells have hitherto been imported from Germany by Mr. Gassner. The new dry cells made in Italy have been tried at the arsenal of artillery and torpedoes at Spezia, and in the telegraph offices of the Meridionali Railway Company, and the results so far obtained have been successful.

Agricultural Machinery.—A trial of seed sowers will be held at an exhibition at Foggia, Italy, on October 20th next. The Italian Government offers two silver medals, a diploma of honour (accompanied by the purchase of five of the winning sowers) to the best machine, a purse of 200 lire, and ten prizes of 30 lire each to the next best machines. Requests for admission to the competition must be sent to the Committee of Direction before September 15th.

National Exhibition at Palermo.—This Exhibition promises to be a great success. The number of exhibitors has now reached 6,000, and includes manufacturers, farmers, artists, manufacturing and agricultural schools, and the exhibitors of the international section. We may cite among the principal exhibitors Messrs. Gio Ansaldo & Co., of Sampierdarena; Messrs. Tardy & Benech, of Savona; the Societá Elvetica, the Societá di Saronno; Messrs. Calzone, of Bologna; Messrs. Grondona, of Milan; Messrs. Diatto, of Turin; and Messrs. Moriggia, of Rome.

NEW YORK, 21st February, 1891.

Locomotives.—The Government of New South Wales has recently ordered twenty-seven American locomotives, for use on a new railroad in that colony, from Philadelphia. The order is based on the advantage of American-built locomotives for climbing heavy grades and turning sharp curves. The freight locomotives are of the heaviest and strongest build, and, with tender attached, will each weigh from 80 to 85 tons, and will be sold for about $10,000 apiece. A special steamer will be ready to take the engines out when complete.

Railway Accidents in the United States.—A return has just been made showing that the number of casualties on the railways of the United States in 1890 was largely in excess of the number reported in 1889, 1888, and 1887, after making due allowance for the increasing railway mileage. The number of persons (passengers, employés, and trespassers) killed in 1890 was 806, and of injured 2,812; against 492 and 1,772 respectively in 1889, 667 and 2,204 in 1888, and 656 and 1,946 respectively in 1887. The number of passengers killed in 1890 was 59 per cent. greater than in 1889, being 172 and 108 respectively, and of employés over 70 per cent. (569 and 336). The three most serious accidents were all due to negligence, and were those of Oakland, California, in May; Quincy, Massachusetts, in August; and Shoemakersville, Pennsylvania, in September; in which 13, 22, and 22 persons respectively were killed.

PHILADELPHIA, 20th February, 1891.

New Engines.—The William A. Harris Steam Engine Company, of Providence, have recently put in a triple compound engine at the Cohannet Mills, Taunton, Mass., of 700 horse-power. They are now putting in a 1,000 horse-power compound at the Wampanoag Mills, Fall River, Mass.; also a tandem compound at the Quincy Market Cold Storage Company, Boston, Mass., in connection with their ice machine. They have just put in a compound of 500 horse-power at the Lowell Electric Light Company, Lowell, Mass., and have in process of construction a duplicate of the same for the Memphis Electric Light Company, of Memphis, Tenn. They are also building low-pressure cylinders to compound two of the engines now running at the Lowell Electric Light Company's station, Lowell, Mass., and have orders for a 400 horse-power compound for F. W. Bird & Son, East Walpole, Mass., and a 1,200 horse-power compound of same type for the Bennett Manufacturing Corporation, New Bedford, Mass.

End of Strike at Iron Works.—The Ellis and Lessig Iron and Steel Company, of Pottstown, Pa., in whose works a strike has existed against a reduction of pay, resumed operations yesterday. More than 450 men are now at work at the former rate of wages. The twenty-two men who were charged with interfering with others who wished to resume work were not re-employed. Three-fourths of the men in the nail works, all in the plate rivet, and about half in the puddle mill, are at work, instead of the total of seven hundred who were at work at the beginning of the strike. The puddlers are working at $3·50 a ton, instead of $4, which they received before the strike began.

Steel and Steel Rails.—The President has transmitted to Congress the report of the Commissioner of Labour on the cost of the production of steel and steel rails, from which the following figures are taken. Reports have been received from 618 establishments, manufacturing various kinds of iron and steel and their finished products. For comparison, the country is divided into two districts. A summary of the cost per 2,240lb. of furnace pig iron is given below:—

	Northern District.		Southern District.
Establishments reporting the facts desired	26	...	28
Cost of all materials used	$6,387,622	...	$5,450,459
Cost of all labour	$1,199,918	...	$1,515,995
Tons of product	544,377	...	649,728
Cost per ton for labour	$2·204	...	$2·341
Cost per ton for material	$11·744	...	$8·141
Total cost per ton	$13·938	...	$10·755

The following is the relative cost of materials per ton in the two districts:—

	Northern.		Southern.
Ore	$4·401	...	$1·513
Scrap, cinder, &c.	2·631	...	1·081
Limestone	0·798	...	0·701
Coke	3·014	...	3·084
Coal	2·695	...	1·566

The division of the amounts paid for Bessemer iron is shown in the following table:—

	Northern.		Southern.
Total charge to blast furnaces	$13·97 to $16·50		$9·16 to $10·61
Labour proper	3·70 to 9·44		4·32 to 7·59
Officials and clerks	·17½ to ·51		·15 to ·19
Supplies, repairs, and taxes	1·69 to 5·32		·66 to 1·21
Transportation	1·69 to 5·32		·36 to 1·5

The cost of making steel rails was, for material $21·10 and $25·11, and for wages $1·54 and $1·38, making the total cost at one establishment $24·79, and at the other $27·68.

Consolidation of Electric Lighting Companies.—A despatch from St. Louis says that the largest transaction in electrical companies ever effected in the West was completed on the 18th inst. by the payment of three million dollars by the La Clede Gas Company, for the purchase of rival electric lighting companies, and to secure complete control of lighting in St. Louis. Two-thirds of this amount was paid for the Municipal Electric Lighting Company, and the balance for the Missouri Electric Company.

Removal of the Delaware Islands.—The tenders for the beginning of the work of removing the Delaware River Islands in front of the city and widening the channel were opened recently in the Government engineer's office. There were only three proposals—that of the Penn Dredging Company of this city, whose tender, on the basis of 17,000,000 cubic yards of material and 18,000ft. of wharfing removed, amounted to $3,232,950; that of the National Dredging Company, of Wilmington, Del., on the same basis, amounting to $3,429,900; and that of the American Dredging Company, of this city, amounting to $3,919,200. The plan is for the formation of a 1,000ft. channel of 26ft., with a cross section of 55,000 square feet in 2,000ft. width, and requires the removal of two islands having a total surface area of about 25 acres. The funds now available amount to $390,000, which covers the work which must be completed by June 30th, 1892.

IMPROVED SAND DRIER FOR LOCOMOTIVES.

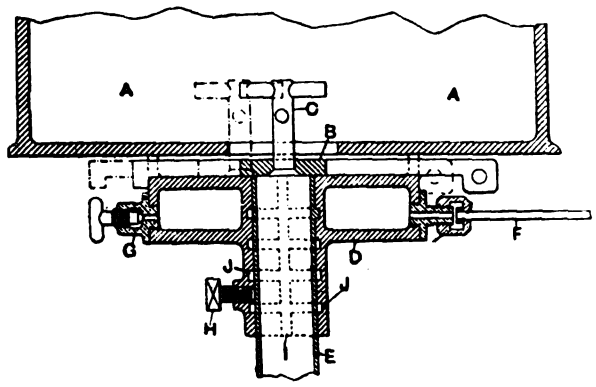

FIG. 1.

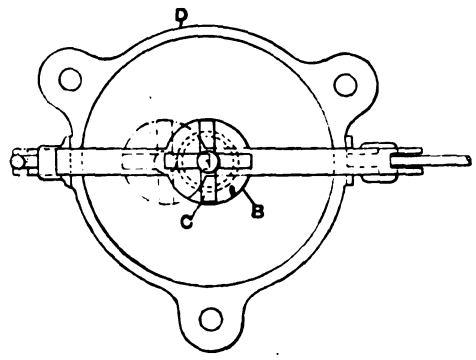

FIG. 2.

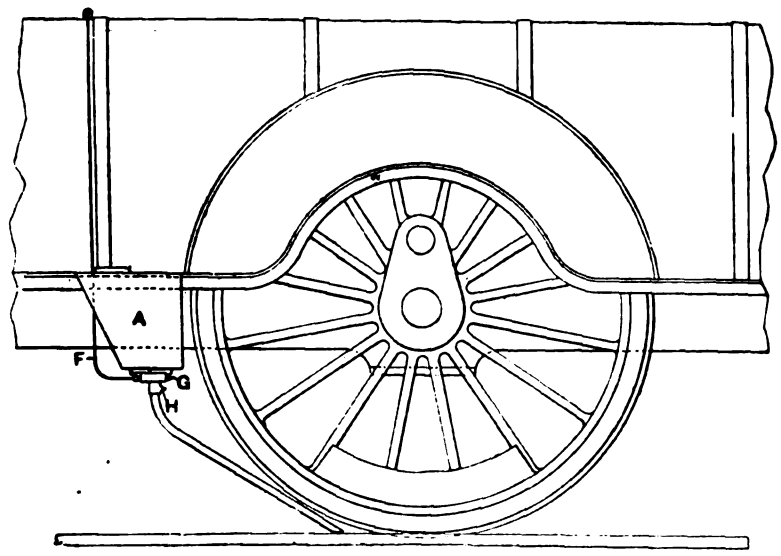

FIG. 3.

IMPROVED SAND DRIER FOR LOCOMOTIVES.

SOME time ago (see *Industries*, Vol. III., page 314) we gave an illustrated description of an improved sand drier as applied to locomotives in order to secure the necessary adhesion of the driving wheels on the rails. The accompanying illustrations show an improved form of this drier, invented by Mr. J. Macdonald, of Tokio, Japan, the agent for whom is Mr. W. E. Heys, 70, Market Street, Manchester. Referring to the illustrations, Fig. 1 represents a vertical section of the drier, Fig. 2 is a plan, and Fig. 3 shows the arrangement as fitted. A is the sand box, B is the sand valve, and C the stirrer. An annular steam chamber D surrounds the sand outlet pipe E, and is supplied with steam by means of a small copper tube F, a drip valve G being also provided to run off the water of condensation. The sand pipe is capable of vertical adjustment, and is secured in any desired position by the set screw H, and by a projection or nib on the pipe which fits into one of the annular recesses. We are informed that this apparatus has been in use on a large number of locomotives for some time in humid climates, with complete success. One line on which it is used has a prevailing gradient of 1 in 80 for a length of fourteen miles.

TRANSFORMER DISTRIBUTION.*

(*Concluded from page* 209.)

TRANSFORMERS.

The loss in the iron in transformers has till lately been very much overlooked; if it is even a small percentage of the full load of the transformer, it mounts up very seriously in station work when the transformers are in circuit all day and all night. The principle of the "Hedgehog" transformer is this: By using an open circuit the iron can be reduced in volume with a given induction. The mean length of the iron part of the magnetic circuit is considerably less, and more copper turns can be wound on without increasing this length much. The additional turns admit of a smaller cross-section of core, so that the iron is enormously reduced. The loss in copper is somewhat increased; but, as the loss in copper is only serious at full load, this does not matter.

The exciting current, though larger than in the case of closed-circuit transformers, is not a serious matter. The loss in copper is considerably smaller than the loss in iron in most closed-circuit transformers, and, as it varies as the square of the current, it is inappreciable except at full load, which very seldom occurs. The loss in iron is very small, so that the loss per day in ordinary working is very much smaller than in the case of closed-circuit transformers.

Perhaps the best way I can make this clear is by a comparison of actual transformers. As an average size of transformer, one taking 2,000 volts and a frequency of 100, and giving 15 amperes at 100 volts, may be taken, and the working compared.

A gun-metal casting forms the backbone of the "Hedgehog" transformer. It is cross shape in section, and at one end is spread out to form four legs. It also supports the lower flange, or cheek, of the winding. The four spaces have bundles of soft iron wire put in, so that the core is practically cylindrical. The cross-shaped core has been criticised on the ground that there are Foucault currents in it. The least consideration will show that there is no change of induction in it, and therefore no Foucault currents. The iron wire is bound tightly, and the two flanges are slipped into place. A gun-metal "spider" is then screwed to the top. It is finally held on by the eye-belt, but temporarily a set screw is used. The core is then wound in a special lathe in the usual way. Both the terminal board and the coil flanges gave us a great deal of trouble till we found suitable materials. There is a great need of good insulating materials that will not warp, that will insulate perfectly, and that can be worked.

The electrical particulars of a fifty 8 candle-power lamp transformer are as follows:—

Core, 13·5in. long, 2·5in. diameter. In taking the area of the core, allowance must be made for the space occupied by the backbone, and for the loss of room in using round wires. Maximum induction, 4,800. Loss of power in iron, assuming it to be of good quality, 13·5 watts. Primary, 3,920 turns of copper wire, 0·042in. diameter; resistance, 37 ohms (warm). Secondary, 200 turns, 19/0·042in.; resistance, 0·098 ohm. Loss of power in primary at full load, due to the transformed current, 21 watts; loss due to the exciting current—0·8 ampere—which is always on, 3·6 watts; loss in secondary at full load, 22 watts. Efficiency at full load, 96·15.

This transformer is shown to scale in Figs. 9 and 10.

Fig. 11 is a scale drawing of a closed-circuit transformer I have taken as representative. The primary is 400 turns of 0·042in. wire, and the secondary 20 turns of 0·176in. The loss in copper at full load is 11·3 watts, and the loss in the iron 120 watts. At full load the efficiency is 91·95, or nearly 92 per cent. The diagram (Fig. 12) shows the percentage loss at various loads of the two transformers. The ordinates are percentage loss, and the abscissæ fractions of full load. Curve II. is the "Hedgehog," and IV. is the closed circuit. It will be noticed that the "Hedgehog's" efficiency increases slightly at first, and keeps above 95 per cent. till the load is reduced to one-fifth, and above 90 down to one-tenth load, and it then begins to fall more rapidly. The efficiency of the closed form, however, begins to fall at once, and falls rapidly. In house-work the full-load efficiency is a matter of little or no consequence; the loss at very light loads is really important. A house that has a 50-light

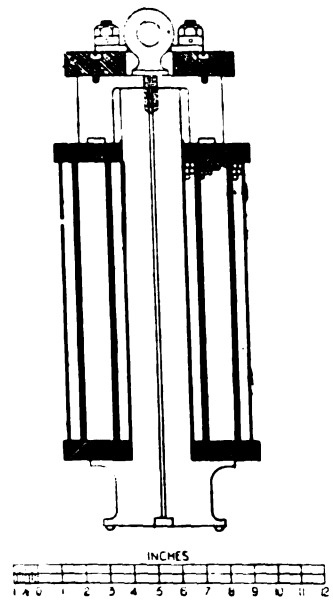

FIG. 9.

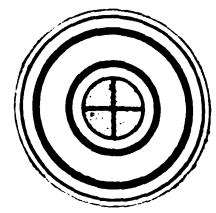

FIG. 10.

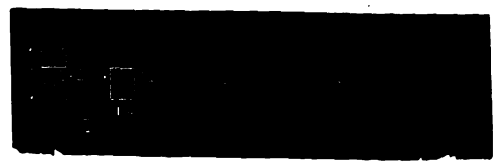

FIG. 11.

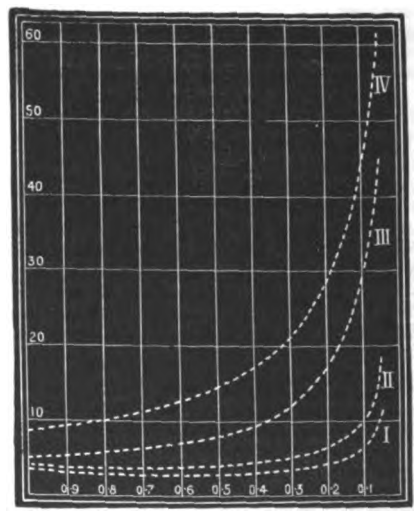

FIG. 12.

transformer is wired for 50 lamps, and that is the maximum load. As a rule, there are seldom more than 25 lamps on at any one time, and these are on during the evening only. It will be a fair average if we take four hours of half-load per day as the output of house transformers. This means an efficiency of 83·3 per cent. for the "Hedgehog," and only 51 per cent. for the closed circuit. In other words, the waste in the closed circuit is between five and six times as great as in the open circuit.

There is no chance of iron being found good enough to allow the closed circuit-form to compete with the open. There is one objection to the "Hedgehog" which must not be passed over,

* Abstract of a paper read by Mr. J. Swinburne before the Institution of Electrical Engineers on the 19th ult.

Digitized by Google

and that is the exciting current. The exciting current in the 50-lighter is 0·31; in the closed circuit it is 0·2; so that it is quite half as much again.

DISTRIBUTION.

Even with the most efficient transformers, the house system is a very poor method of distribution. Apart from the question of loss of power, consider the outlay involved in providing each consumer with a high-pressure double-pole fuse, a transformer, an automatic device for rendering the whole arrangement safe in case of insulation giving way, perhaps a double-pole main switch, a meter, and a fire-proof safe in which all these things have to be enclosed. In addition to this, it involves a complete high-pressure parallel system of distribution, and a network of 2,000-volt underground mains, involving a heavy outlay, and probably heavy depreciation. There is no need for sub-stations; the low-pressure network may be fed at various points by transformers and feeders coming direct from the station. These transformers need not be in houses or cellars; they can be placed conveniently in the ground in cases filled with insulating oil. At the station each feeder can be regulated, and has a compound-wound voltmeter, so that an attendant can keep the pressure in the whole town constant. As Mr. Kapp pointed out in 1888 the advantage of such a system is enormous. In direct currents the low-pressure mains must be large.

Even in scattered districts it would generally pay to use small low-pressure mains and feeders. The alternate system has so many advantages over the direct in the matters of regulation and distribution, when worked on the low-pressure system, that it is astonishing that such arrangements are not utilised. For instance, with direct currents, it is most difficult to find a leak; and one leak on the positive at the west end, combined with one leak on the negative at the east, will cause serious trouble. With alternate currents, a number of small local networks may be used, each of them being complete in itself. It is not in metallic connection with any other part of the town, nor with the central station. Where it meets the network of the neighbouring district it is not metallically joined, as in the case of direct currents, but is connected through a one-to-one transformer sunk in the ground, in a case full of oil.

After the clear and able manner in which Mr. Kapp urged the advantages of low-pressure networks for alternating currents, it is most astonishing that engineers should go on with house transformers. At present, however, we are using alternating currents in just about the worst way that could be possibly devised.

CONDENSERS.

Condensers may have a very large opening in connection with ordinary alternate-current distribution. Take the case of arc lamps. For instance, suppose a station supplies a 100-volt secondary circuit by means of transformers with 2,000 volts primary pressure; and suppose there are 200 arc lamps, each taking 33 volts and 10 amperes, arranged on the 100-volt circuit, with a choking coil in series with each. Suppose, for simplicity, that there are no incandescent lamps in use. The arc lamps then take 2,000 amperes and 100 volts; but this does not amount to more than 66,000 watts, as the current is not in step with the electromotive force. The dynamos thus have to supply 2,000 volts and 100 amperes; whereas the same power, if the current did not lag, would be supplied by 2,000 volts and 33 amperes. This gives rise to several troubles. Suppose each machine has an armature wound to give 2,000 volts and 33 amperes, or 66,000 watts, it takes three instead of one to work the lamps. In addition to this, the lagging of the current weakens the field of the dynamos, so that they need more excitation to give 2,000 volts than they would need even on full load on a non-inductive resistance. Moreover, running three engines and dynamos at a third load instead of one at full load is not economical. A condenser takes a current which leads relatively to the pressure, so that it counteracts the effect of the lagging current. The 100 amperes may be regarded as compounded of 33 amperes in step with the pressure, and 95 amperes lagging a quarter of a period. A condenser of about 85 microfarads will supply the 95-ampere component, while one dynamo supplies the 33 amperes really needed by the lamps. This reasoning holds good without the curve of sines assumption.

The use of condensers to overcome troubles arising from exciting or magnetising currents of closed or open circuit transformers has already been mentioned.

The commercial manufacture of high-pressure condensers is not easy, but it may now be said that it can be carried out.

SHIPBUILDING NOTES.

ON the 14th ult. the fine screw steamer "Taurus," built by Messrs. Wm. Gray & Co., Limited, to the order of Mr. Wilhelm Wilhelmsen, of Tonsberg, Norway, went on her trial trip. The dimensions of the vessel are:—Length, over all, 288ft.; breadth, 37ft. 2in.; depth, 21ft. 2in. The engines, which are of the triple-expansion type, have been supplied by the Central Marine Engine Works, of Messrs. Wm. Gray & Co., the cylinders being 21½in., 34in., and 57in. in diameter, with a piston stroke of 39in. Steam is supplied by two large steel boilers working at a pressure of 160lb. The vessel takes Lloyd's highest class, and is fitted with all the latest improvements, including a "Yaryan" evaporator. After adjustment of compasses, a run was made to sea for above an hour at full speed, the engines making upwards of 90 revolutions per minute during that time, and a speed of 12½ knots was maintained.

ON the 16th ult. the s.s. "Justin," a steel screw steamer, built for Messrs. Arthur Holland & Co., London, by Sir Raylton Dixon & Co., Middlesbrough, took her trial trip from the Tees. This vessel is built on the web-frame principle with poop, raised quarter-deck, bridge, and top-gallant forecastle. Her dimensions are:—Length, over all, 287ft.; breadth, 39ft.; depth, moulded, 21ft. 3in.; with a dead-weight capacity of about 3,300 tons. Her engines were supplied by Messrs. Blair & Co., Limited, Stockton, having cylinders 21in., 35in., and 57in., with 39in. stroke, and gave every satisfaction.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, March 6th, at 9 p.m. Lecture on "Electromagnetic Repulsion," by Professor J. A. Fleming. Saturday, March 7th, at 3 p.m. Lecture IV., on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

SANITARY INSTITUTE.—Friday, March 6th, at 8 p.m. Paper to be read: "Objects and Methods of Inspection," by Mr. J. F. J. Sykes.

SOCIETY OF ARTS.—Friday, March 6th, at 4.30 p.m. Lecture on "The Science of Colour," by Captain Abney, F.R.S.

GEOLOGISTS' ASSOCIATION.—Friday, March 6th, at 8 p.m. Paper to be read: "On the Structures of Igneous Rocks," by Mr. J. J. H. Teall, F.R.S.

BALLOON SOCIETY.—Friday, March 6th, at 8 p.m. Paper to be read: "The Movable Dwellings Bill," by Mr. M. I. Lyons.

NEXT WEEK.

SOCIETY OF ARTS.—Monday, March 9th, at 8 p.m. Cantor Lecture I., on "Photographic Chemistry," by Professor R. Meldola, F.R.S. Wednesday, March 11th, at 8 p.m. Lecture on "Electricity in Relation to the Human Body," by Mr. H. N. Lawrence and Mr. A. Harries.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Monday, March 9th. Paper to be read: "Electrical Engineering" by Mr. W. C. Mountain.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, March 10th, at 8 p.m. Ordinary meeting. Paper to be discussed: "On the Subterranean Water in the Chalk Formation of the Upper Thames, and its Relation to the Supply of London," by Mr. J. T. Harrison, M.Inst.C.E.

SANITARY INSTITUTE.—Tuesday, March 10th, at 8 p.m. Paper to be read: "The Nature of Nuisances, including Nuisances the Abatement of which is Difficult," by Mr. J. F. J. Sykes. Wednesday, March 11th, at 8 p.m. Paper to be read: "The Prevention of Infectious Diseases," by Professor A. Wynter Blyth.

SOCIETY OF ARCHITECTS.—Tuesday, March 10th, at 7.30 p.m. Paper to be read: "Land and House Property in London, and Modern Attempts to Disturb their Character," by Mr. W. Woodward.

ROYAL INSTITUTION.—Thursday, March 12th, at 3 p.m. Lecture on "Modern Chemistry in Relation to Sanitation," by Professor C. Meymott Tidy.

PRICES CURRENT, 4TH MARCH, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: There is no change to report in the position of the copper market, which continues quiet. Values of manufactured remain unchanged, prices being well maintained, although the demand is small. Chili bars are changeable, and lower on the week, to-day's quotations being £52 7s. 6d. to £52 12s. 6d. cash, with small trade reported. Manufactured £65, "strong."

TIN: Fairly steady at last week's rates, with better inquiry.

LEAD: Quiet and unchanged.

SPELTER continues very firm, all the makers being short of stocks, and fully sold for some months to come. There is a good demand, and prices are likely to be well maintained at the present high values.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: There is only a moderate amount of business passing, and values of many articles are weakening. Sulphate of ammonia is again easier, and very little doing. Sulphate of copper has lost a portion of the recent advance. Green copperas is unchanged in value, but has less inquiry. Yellow prussiate of potash remains firm; chlorate of potash also. Bichromates quiet, but steady. Foreign white sugar of lead is firm at the advance; other lead salts are quiet.

HOME INDUSTRIES.

LONDON, 5th March, 1891.

The Money Market.—There has been no feature in the money market, except the maintenance of a steady though not great demand for gold for abroad, which keeps rates fairly firm. Early this week the floating supply of money was reduced somewhat by operations in connection with the transference to the County Councils of funds collected by the imperial authorities and handed over in accordance with Mr. Goschen's scheme of two years ago. This strengthened money rates for a short time. Business on the Stock Exchange continues on a very limited scale. Last week there was a revival of serious rumours regarding the solvency of some houses concerned in South American loans, and this week these reports were again circulated owing to heavy sales of Consols for money. But the impression is that these sales, so far from indicating further danger to the market, were due to strong steps being taken to avert all risks by the provision of money to tide over the undoubted temporary difficulties of some firms. In the home railway market the declaration of the Scottish dividends has caused a sharp fall in their stocks, the strike having cut more severely into net revenues than had been calculated. American and Canadian railways have been dull and listless. Foreign bonds have been generally firm, and silver securities have improved somewhat. Industrial, miscellaneous, and mining shares have shown little life.

Institution of Mechanical Engineers.—The ensuing ordinary general meeting of this Institution will be held on the 19th and 20th inst., at 7.30 p.m., at the Institution of Civil Engineers. The President, Mr. Joseph Tomlinson, will be in the chair. The following papers will be read and discussed:—"Fourth Report of the Research Committee on Friction: Experiments on the Friction of a Pivot Bearing," "On Recent Trials of Rock Drills," by Mr. Edward H. Carbutt and Mr. Henry Davey.

Metropolis Water Supply Bill.—On the 27th ult. a meeting of representatives of district boards and vestries was held, to take into consideration the Metropolis Water Supply Bill. Sir Algernon Borthwick, who presided at the meeting, said that the evils of the present system were apparent, and a remedy must necessarily be sought. The various companies should be consolidated so as to be managed under one administration, and additional supplies of water should be obtained from Leatherhead, Rickmansworth, and other places. The cost of buying out existing water companies would only be increased by any delay. Mr. H. Wilkins, the hon. secretary of a committee of district board members appointed to deal with the subject, then presented a summary of the Bill, which proposed to confer upon an elected water trust the exclusive powers of supplying water within the metropolitan area, and for securing an equalisation of charges for such supply. The trust would consist of thirty-nine members, elected by the county electors of the water area. A board of arbitration would fix the terms upon which the water companies should be bought out. The purchase-money would be paid by stock secured on the property of the water trust, and by rates levied over the whole area. It was provided that the London County Council might take the place of the trust, but preference was expressed for the latter, seeing that the area administered would be beyond the London area. A resolution was subsequently carried unanimously that it was desirable that the water supply of London should be with the least possible delay vested in a public representative authority.

Exhibition of Meteorological Instruments.—On the 3rd inst. the annual exhibition of instruments, under the auspices of the Royal Meteorological Society, was opened in the rooms of the Institution of Civil Engineers, and will remain open until the 19th inst. This year the Exhibition includes rain and evaporation gauges, and any new forms of instruments which have been invented during the past year. A large variety of gauges are exhibited, including those of older types. Specimens of gauges used on the Continent and in the United States are also shown. The evaporation gauges include several instruments employed for measuring the evaporation from a free surface of water, and others for use with growing plants. A number of new instruments are also exhibited, among which are various anemometers, recording barometers, and cameras for meteorological photography. An interesting collection of maps of rainfall over the British Isles and various parts of the world, as well as numerous photographs of floods and meteorological phenomena, are also on view.

Compound Sulzer Engine.—We had this week an opportunity of inspecting a horizontal compound steam engine, the first that has been constructed in England on the well-known Sulzer system. The engine, which has been constructed by Messrs. Bryan Donkin & Co., Limited—who have been appointed by Messrs. Sulzer Frères, of Winterthur, as the sole makers for Great Britain and Ireland—at their works, Southwark Park Road, Bermondsey, is capable of indicating 400 horse-power with a boiler pressure of 90lb., and has been constructed for Palmer's Ordnance Works, Jarrow. We hope in a later issue to give illustrations and further particulars of this engine, which is constructed on a principle largely adopted on the Continent.

The Torpedo Gunboat "Antelope."—The Admiralty have placed the order for the machinery of the torpedo gunboat "Antelope," now building at Devonport, with Messrs. Yarrow & Co., of Poplar.

MANCHESTER, 5th March, 1891.

The Late Dr. Joule.—At the ordinary meeting of the Manchester Association of Engineers, held on the 28th ult., Mr. John Angell delivered a paper descriptive of the labours of the late Dr. Joule during his demonstration of the mechanical equivalent of heat. The paper dealt to some extent with the previous history of the subject, and was illustrated by a number of lantern views of the various forms of apparatus devised and employed by Dr. Joule in the course of his experiments. Of these and the mode of using them Mr. Angell gave a lengthy description, and concluded by showing some of the applications which had been made of Joule's work. The paper forms a very complete summary of the work of Joule in this connection, and for this reason is valuable.

Improved Slow Motion for Carding Machines.—Mr. George Paley, of Preston, has just devised a novel and ingenious motion for reducing the speed of carding engine cylinders during stripping and grinding. The whole of the mechanism is enclosed within the driving pulleys, and consists of a wheel affixed to the boss of the fast pulley with fifty teeth. A loose bush is placed inside the loose pulley on which the latter revolves, and on the inner end of the bush a wheel containing fifty-one teeth is keyed in a position adjoining the previously-named wheel. The outer end of the bush is formed with a flange, in which several holes are drilled, so that by means of a rod any rotation of the bush can be prevented. A pinion long enough to engage with both wheels is carried on a pin fastened into the web of the loose pulley, and is, of course, rotated with it. When the fast pulley is revolved during ordinary work the whole mechanism is carried round by it, but when the strap is moved on to the loose pulley for grinding or stripping, the bush is prevented from turning by the introduction of a rod into one of the holes, the rod being suitably fixed. The result is that the pinion rolls round the wheel on the bush, and, owing to the difference in the number of teeth in the two wheels, gives a rotary movement to the extent of one tooth to the wheel on the fast pulley boss during every complete rotation round the other wheel. Thus, in the case named, the rotation of the fast pulley is reduced to $\frac{1}{50}$th of that of the loose pulley, which gives a motion sufficiently slow for grinding. This motion enables mechanical stripping to be done, which has hitherto been a difficult task.

Proposed Tower at Blackpool.—The borings for the foundations for a new tower, on the model of the Eiffel Tower, have been commenced in Blackpool, on a site adjoining the promenade. The capital proposed is £150,000, much of which has been subscribed. It is intended to erect a three-storied building, from the centre of which the tower will spring. M. Eiffel has been asked to act as consulting engineer.

The Iron Trade.—The condition of local trade is very poor, and only a small business is being done. There is a widespread opinion that the price of iron will be lower than at present, and buyers are very unwilling to contract. The failures in the West Cumberland section have somewhat disorganised trade in hematites, but, on the whole, business has not suffered so much as might have been expected. Bar iron is very slow of sale, and prices are continually drooping. There is a difficulty in getting new business, which does not become less as the season advances. Generally speaking, the outlook is not a very favourable one.

The Linen and Jute Trades.—There is a fairly active movement this week on home trade account, but no improvement can be reported in the shipping branches. Manufacturers, notwithstanding the hesitation shown by buyers in placing orders, and their evident determination to keep stocks down to the lowest workable level, are disinclined to make any concessions in price, as the increase of late in cost of production places them in a much more awkward position. There is fortunately a disposition on the part of Continental spinners and manufacturers to assist the efforts of British firms in this respect, and, with the absence of the reckless cutting of prices that has characterised the action of foreign firms in previous years, the position of the trade is less uncertain. Coarse goods are not so weak as they were, and, although the demand is quiet, sellers are hopeful. Distribution generally in the warehouses has not, however, been so brisk as would have been the case had the season been at its best, and it is not expected that the year will yield results equal to those of last. The shipping demand is unchanged. There is a continuance of the dulness previously noted in the South American branch, the mails of the 3rd inst. not having brought satisfactory news. United States buyers have not yet commenced to arrive in appreciable numbers. For Canada there is not much doing. Another somewhat extensive failure has had a depressing effect, and the slowness of remittances in the Dominion puts a great strain upon the wholesale houses there. Hessians are in steady request.

GLASGOW, 5th March, 1891.

The Scottish Railways.—More than usual interest attaches to the declaration of the half-yearly dividends by the three railways affected by the recent strike. For some time the shares of all have been depressed, at first in consequence of apprehensions of a strike, and afterwards by reason of the strike itself and of the effect of the heavy losses of the companies in reducing the dividends. In Glasgow and South-Western stock there was a fall of £2 12s. 6d. in five days, in consequence of the rumours about the dividend. Caledonian and North British ordinary stock have both lost ground during the past few days, North British ordinary preference falling sharply in the beginning of the week. These falls indicate the heavy losses due to the crisis through which the companies have been passing. In addition, there has been, during the past few months, a slowness of trade, apart from the influence of the strike, and this would in any case have told against the dividends even had there been no strike.

Declaration of Railway Dividends.—The Glasgow and South-Western Company have declared a dividend for the half-year at the rate of 3¼ per cent. per annum, and the Caledonian a dividend at the rate of 3¾ per cent. per annum. The dividend of the North British Company will not be declared until the 12th inst. The ordinary stock of the North British Company has fallen sharply ever since the close of the strike, owing partly to the losses due to the strike, partly to the falling off of traffic due to the want of expansiveness in trade, and partly to the collapse of the North British scheme for the acquisition of the Glasgow and South-Western Railway. The dividend of the Glasgow and South-Western Railway is regarded as being quite as much as was expected. The winter dividend of this company was 4 per cent., 4 per cent., 3¼ per cent., 3¾ per cent., and 4 per cent. during the past five years. It must be remembered that the strike on the Glasgow and South-Western system lasted only ten days. The Caledonian dividend is so much smaller than had been anticipated that the stock dropped at once on the declaration from 116⅜ to 115¾. The dividends for the winter half-years of the Caledonian were 5¼, 5½, 4, 3¾, and 4 per cent. for the past five years. The dividend is lower than in any winter half-year since 1881. Assuming that the difference of 1¼ per cent. per annum is due to the strike, this represents a loss to the Caledonian Company of about £75,000. The ¼ per cent. per annum of difference on the Glasgow and South-Western dividend represents a loss of about £12,500. In this connection the Clyde Trust reports a decrease of revenue due to the strike amounting to between £5,000 and £6,000.

Pig Iron.—The continued depression of the pig iron market, and the obvious impossibilities of holding out, have compelled the blast furnacemen, after a strike or lock-out of twenty-one weeks, to sue for terms. They have offered to abandon their original demand for extra payment for Sunday labour, but the ironmasters refuse to take the men back excepting at a reduction of 20 per cent. The men have offered to agree to a deduction of 12½ per cent., but as yet there seems little prospect of a compromise being effected. Prices are still low, but warrants are said to be scarce, and the market has for some days been fairly firm, holders being by no means sure that a rebound from present low prices is not imminent. Meanwhile Scotch iron is going out of stores, the make of the furnaces recently put in blast being all absorbed by the current demand for special brands. The importation of Cleveland iron has been checked. The effect of the shutting down of Scotch furnaces during a period of almost utter quiescence, while the Cleveland ironmasters sent their iron into Scotland at ruinous prices, has been the reverse of satisfactory for the Cleveland makers. The failure of one of them, and the probable stoppage of the furnaces of others, may perhaps help to check the fall which has been going on in spite of the suspension of Scotch production. If, as is alleged, the Cleveland ironmasters were indirectly instrumental in facilitating the lock-out of blast furnacemen in Scotland by subsidising their union, there can be but little sympathy in Scotland for their present misfortunes. It must be said, however, in the first place that there is not an atom of direct proof that they supported the Scotch blast furnacemen in their dispute with their employers, and in the second place, that the blast furnacemen's dispute had very little to do with the stoppage of the production.

(From our own Correspondents.)

LIVERPOOL, 4th March, 1891.

The Port Sanitary Authority.—The annual report of the Medical Officer of Health was presented to the Council to-day, and contained some interesting statistics. The number of vessels inspected during the year was 3,372, of which 3,102 were found to be in good sanitary condition, and only 270 defective, the condition of the British ships reflecting great credit on the officers and men. The number of emigrants which passed through the port was 190,785, being 7,070 less than the previous year; the falling-off consisted of 10,915 English emigrants, 731 Scotch, and 818 Irish, while there was an increase of 5,394 foreign emigrants.

The Trade of Liverpool.—At the last meeting of the Dock Board it was stated that the trade of Liverpool, measured by the tonnage of vessels using the port, was making steady progress. The Board have therefore been compelled to seek Parliamentary powers for providing additional accommodation commensurate with the requirements of the port. While in 1881 the tonnage of the port was 7,894,000 tons, last year it had risen to 9,654,000, and for the first time in the history of the Dock Estate the revenue derived from rates on ships and goods had exceeded £1,000,000.

Electric Lighting in Liverpool.—At the meeting of the shareholders of the Liverpool Electric Supply Company, held last week in Liverpool, it was stated that the profits for the last twelve months amounted to £4,878, out

Digitized by Google

of which it was proposed to pay a dividend of 3¼ per cent.; the expenditure on capital account amounted to £54,019. The number of lights supplied on January 1st, 1890, was 6,700, and on January 1st of this year 11,750, the present available engine power being for 25,000 lamps. It is proposed to extend the business of the company into the suburbs to Prince's and Sefton Park.

SHEFFIELD, 4th March, 1891.

Iron and Steel.—Messrs. Vickers, Sons, & Co., Limited, have received an order from the English Government to supply the side armour for the second-class battleship "Centurion," one of the ships built under the naval programme which was sanctioned three or four years ago. The plates will be of solid steel throughout, as the firm do not make composite plates, and they will vary in thickness from 8in. to 12in. Messrs. Cammell are to supply side armour to the "Barfleur," which will be made on the compound system under Mr. Wilson's patents. Other branches of the heavy trades are fairly well employed. The capacity of the large manufactories for turning out work of the heaviest kind here is very great. Lathes capable of dealing with work that measures 6ft. by 60ft., and weighing up to 100 tons; boring machines, with beds 100ft. long, that are able to bore shafts 60ft. in length, perfectly true from end to end; and planing machines that weigh 120 tons, are becoming quite common. The railway and rolling stock works are fully employed. Mr. C. D. Clayton, of Doncaster, is building a large shop at Mexborough for the manufacture of rolling stock and for doing repairs.

Fuel.—The prices of fuel show a tendency to decline, although the local demand is brisk. Household coal is selling at a very high price, and without much hope of an early reduction. Steam coal is in active request for locomotive use, and also the commoner qualities for general manufacturing purposes. Coke of various qualities is in rather less demand, more especially of the quality used for blast furnaces, and the stopping of the Scotch and Staffordshire ovens has contributed largely to this result. Colliery owners are now finding considerable difficulty with their men, who are threatening to strike.

The Late Mr. William Fox.—The death of Mr. William Fox occurred at Harrogate on the 27th ult. Mr. Fox was connected with various business undertakings—the Leeds Forge, the British Water Gas Syndicate, and the Yorkshire Water Gas Company.

NORTH STAFFORDSHIRE, 4th March, 1891.

The Iron Trade.—There is no improvement to record in the outlook of the iron trade in this district, and the further fall in prices, owing to the keen competition which prevails, is really of an alarming character. The fact that miners' wages are still maintained at so a high a point, by reason of which the cost of production of minerals—both coal and ironstone—is greatly enhanced, accounts for the position in which ironmasters are now placed. It is rumoured that one ironworks in the district, which was only restarted a short time ago, has gone into liquidation, and that a receiver has been appointed. Unless prices improve, of which there seems little prospect, other works will have, of necessity, to stop their mills and forges. The price of pig iron has fallen from 3s. to 4s. per ton during the last few weeks, and it is an open secret that many sales are being effected at an absolute loss to the makers.

General.—The annual meeting and dinner of the North Staffordshire Institute of Mining and Mechanical Engineers and the annual dinner of the North Staffordshire Chamber of Commerce were held at Stoke last week.

DERBY, 4th March, 1891.

The Midland Railway.—A dividend at the rate of 7 per cent., in the face of the increased price of fuel and higher wages, was announced by Mr. George Ernest Paget, the newly appointed chairman of the company, at the recent half-yearly meeting. The receipts have increased as follow:—Traffic receipts increased £226,929; miscellaneous receipts, including balance, increased £6,912; altogether an increase of £243,841. This had been absorbed as under:—Increased working expenses, £180,841; interest and dividend on increased capital, £24,880; ¼ per cent. more dividend on ordinary stock, £37,768; and increased balance carried forward, £352. A strenuous opposition will be offered by the Midland Railway Company to the schedule of maximum rates to be proposed by the Board of Trade to Parliament, which materially differs from the draft schedule prepared by Lord Balfour of Burleigh and Mr. Courtney Boyle. They estimated that, even under the last-named schedule, the revenue of the company would be compulsorily reduced by about £100,000 a year, but, bad as these were, the Board of Trade are now offering much worse terms.

CARDIFF, 4th March, 1891.

Iron and Steel.—The hematite pig iron trade is in a deplorable condition, and the news that a large company in the Cumberland district has suspended payment has not tended to brighten affairs. At Rhymney the intention to close the Bessemer steel mills was carried into effect on the 28th ult. The iron ore market is quiet, but one or two sales have been reported. Rubio ore is quoted at 13s. 9d. to 14s. c.i.f. Cardiff or Newport, 14s. 6d. Porthcawl, 14s. 9d. Port Talbot, 14s. 6d. Briton Ferry, and 14s. 3d. Swansea, for 50 per cent. iron as received.

Coal and Coke.—The shipments of steam coal continue large, but collieries do not feel the strain so much, there having been an accumulation of loaded waggons. The tone of the market has not materially changed since last week. Inquiries are not so numerous, and, owing to the closing of some steel mills, the quantity of coal for sale is likely to be increased. Prices are steady. Steam coal realises—1st quality, 14s. 9d. to 15s. 3d.; 2nd, 14s. to 14s. 6d.; 3rd, 13s. 3d. to 13s. 9d.; and 4th, 12s. 6d. to 13s. Small steam coal finds a very poor outlet, prices being quoted at 5s. to 5s. 3d. The household coal trade is fairly active, but there is no evidence of the pressure noticeable a few months back. Patent fuel is quiet.

BARROW-IN-FURNESS, 4th March, 1891.

Hematite.—There is less activity in the hematite pig iron trade, and prospects are very poor. In fact a further reduction in the number of furnaces in blast has been necessitated at the works of the Maryport Hematite Company, where only one of the four furnaces is now blowing. This company has found it necessary to suspend payment because of its inability to produce iron at a profit—one of the effects of speculation in hematite warrants, and of the accumulation of heavy stocks of metal. The stocks held in the district have been reduced this week by 3,698 tons, but still stand at 205,784 tons. Prices are practically unchanged at 51s. for hematite warrants net cash, and 52s. to 53s. for mixed Bessemer numbers net f.o.b.

Steel.—In the rail trade there is a marked quietness, and orders are given out sparingly. The mills are not regularly employed, and the outlook is cheerless. Heavy sections of rails are at £4 15s. per ton. An improvement is noticeable in the steel shipbuilding material trade, the result of recent heavy inquiries for early deliveries of plates, angles, and other sections required by shipbuilders for some important contracts which are at present in the market. As a consequence of this prices have advanced to £6 10s. for plates, while angles are at £6 and boiler plates at £7 5s. Other departments of the steel trade are quiet, except those of hoops and heavy steel castings, which are very brisk.

Barnes' Patent Steel Rail Pit Props.—Under the head of "Propping Plant for Mines," reference was made to this invention of Mr. Barnes, of Harrington, in a recent letter. It should have been mentioned that these props and supports have a series of notches or cuttings in the rails for framing them together in the several positions for which they are intended.

MIDDLESBROUGH, 4th March, 1891.

Pig Iron.—The market is firm but rather lifeless, not much business being done. Buyers of No. 3 G.M.B. are plentiful at 42s. per ton for early, and 42s. 3d. for forward delivery, but sellers hold back, since they expect better prices as the season advances. Middlesbrough warrants are 42s. 1½d. cash buyers, but there is no great demand. The stock in Connal's store on the 2nd inst. amounted to 124,568 tons, being an increase since the 28th ult. of 139 tons. In hematite pig iron East Coast brands are 54s. per ton f.o.b. sellers. West Coast brands have been quoted at 50s. 11½d. cash.

Shipments.—February has been a splendid month for shipments of pig iron, but this has been caused by the demand from Scotland, which took 37,432 tons of the total 70,499 tons. The shipments for the same month last year amounted only to 41,967 tons. The shipments of manufactured iron and steel, on the other hand, have fallen off considerably. Those of manufactured iron amounted to 18,401 tons against 22,491 tons last year, and those of steel to 17,965 tons against 30,186 last year.

Manufactured Iron and Steel.—Business is very dull, and the prospect cheerless. Prices remain as they were:—Iron ship plates, £5 15s.; steel ship plates, £6; iron ship angles, £5 12s. 6d.; steel ship angles, £6; iron bars, £5 15s.; steel rails, £4 15s. per ton f.o.t. at works, less 2½ per cent.

Dividends.—Messrs. Bolckow, Vaughan, & Co.'s directors have decided to recommend a dividend for the half-year ended December 31st last of 3 per cent., making altogether 6 per cent. over the entire year. The Teeside I. & E. Works Co.'s directors propose to pay a dividend of 7½ per cent. on the preference shares, and 2½ per cent. on the ordinary shares.

Ironmasters' Returns.—These have just been issued for the month of February, and show a decrease in the make of pig iron of all kinds of 19,362 tons, there being two furnaces less blowing. They also show a decrease in stocks of 2,940 tons, as against the amount at the end of January. The stocks at the end of February amounted to 287,341 tons.

SUNDERLAND, 4th March, 1891.

The Shipping and Coal Trade.—There is no improvement in the local coal trade, and the continuance of the Silksworth strike is being severely felt. During the month of January the revenue of the River Wear Commissioners showed a decrease of £2,147 3s. for the month Some steps should be taken to encourage other trades as the port is too much dependent upon one or two industries.

Shipbuilding and Engineering.—During the present year eleven vessels, of 25,146 tons, have been launched at this port, eight, of 18,944 tons, during the month of February, as against three, of 6,202 tons, in January. All are screw steamers, except the large sailing ship "Honresfeld," launched by Messrs. William Doxford & Sons, Pallion. Inquiries are less scarce, but few contracts have been taken this year. Messrs. Short Bros., Pallion, have secured two orders for screw steamers, one of which is of 3,000 tons deadweight on a light draught, for the River Danube trade, and the other for the Scotch coasting trade. Marine engineering establishments continue to be actively employed. Amongst the work in progress at the Southwick Engine Works (Messrs. George Clark, Limited) is a set of triple-expansion engines to be shipped to Bergen, and some "Yaryan" evaporators for steamships.

The Glass Trade.—This trade is fairly flourishing, but in the sheet and rough plate glass departments the cost of labour is severely felt. Messrs. J. Hartley & Co., after having given due notice of 10 per cent. reduction to their employés, have locked them out, as the reduced wages were not accepted.

NEWCASTLE, 4th March, 1891.

The Coal Trade.—The condition of the local coal trade has undergone little change since last week, but the qualities required for steamers' uses are less inquired for, and, to prevent an accumulation of stocks, the production will probably have to be lessened. The demand for gas and household coals has also shown more weakness, but for manufacturing coals there is still a fair amount of inquiry. The shipments of coal and coke at Tyne Dock for the week ending on the 28th ult. amounted to 96,399 tons, being a decrease, as compared with the shipments in the corresponding week last year, of 4,275 tons.

Engineering.—The overtime question continues to disturb the relations between employers and employed in this district. A meeting of operatives' representatives was held in Newcastle with reference to this matter on the 28th ult., and arrangements are in progress for the discussion of the subject with the employers at an early date. The fitting of the machinery of the second-class cruiser "Pique," which was launched from the Palmer's Shipbuilding and Iron Company's yard a few weeks ago, is now nearly completed, and the vessel will be ready for her preliminary trial very shortly. The steel crank-shafts for this vessel, each of which, though of the tubular type, weighs nearly 6 tons, have been supplied by Messrs. Charles Cammel & Co., of Sheffield, through their Newcastle agency, and the same firm have also orders from Messrs. Palmer's Company to supply the crank-shafts for the "Rainbow" and "Retribution." These vessels are also cruisers of the second class, and are being built by the Palmer's Company for the Admiralty. A further important order for shafting has been received by Messrs. Cammell & Co. from the same firm of shipbuilders, and several other good orders from Tyneside firms have recently been secured through the Newcastle agency.

Hydraulic Riveting.—The system of riveting by hydraulic power is being successfully applied to the shell plating of vessels now in course of construction in a Tyneside shipbuilding yard. In this district the application of machine riveting to ship construction has hitherto made little progress; but it would seem that attention is now being more strongly directed to the subject, with the result that the advantages of machine riveting are being appreciated.

Electric Lighting.—Messrs. J. H. Holmes & Co., electric lighting engineers, are extremely busy, having plenty of orders in hand for both land and steamship installations. Messrs. C. A. Parsons & Co. are also well supplied with work, and their establishment at Heaton is likely to be kept briskly employed for some months to come.

Newcastle Association of Students of the Institution of Civil Engineers.—The inaugural meeting of this Association was held on the 25th ult., Mr. P. J. Messent, M.Inst.C.E., being in the chair. The chairman gave a brief account of the formation of the Institution of Civil Engineers, and of the advantages of belonging to it. Mr. P. J. Messent was elected President of the Association of Students. In the name of the Council of the Durham College of Science, Principal Garnett placed a room at the disposal of the Association in which to hold its meetings.

BELFAST, 4th March, 1891.

Shipping.—In spite of the fact that shares in shipping property are not accepted as security by the Irish banks, the tonnage owned in Belfast has been more than doubled within the last five years. The Crown Steamship Company, Limited, has been formed, with Mr. D. C. Kemp as chairman, and Messrs. Wm. Gibson & Co. as managers. The "Crown of England," the company's first steamer, is being built by Messrs. Richardson & Duck, Stockton-on-Tees. Another Belfast ship, the "Ramore Head," which is to carry 6,500 tons, lately launched by Messrs. Workman, Clark, & Co., Limited, is now being fitted with her engines at Glasgow, and the same firm are finishing a large sailing barque for Messrs. W. I. Woodside & Co., of this town.

General Trade.—The linen business is just now rather flat. The supply of home-grown flax is rapidly falling off. The building trade is very active at present, and the price of bricks has increased 25 per cent. Rapid progress is being made with three large public works—namely, the new blue dock for the Harbour Commissioners, the Stoneyford Waterworks, and the Main Drainage Scheme.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 399, Strand, London, W.C.*

FRIDAY, 6TH MARCH, 1891.

SANITARY PROGRESS.

THE influence of modern industry on sanitary conditions is a subject which is attracting increasing attention on the part both of the general public and the legislature. It is well, therefore, to note occasionally the progress which is being made, so that we may compare our present position with the past, and thus be able to form some idea of the direction in which we are moving. The works of such men as Sir John Simon and Dr. Farr, to whom the British public owe so much, enable us to make such an estimate as we suggest, and at the present time, when the whole subject of factory legislation is being discussed, it may be interesting to our readers if we note a few facts in the history of sanitary science. We do not require to go very far back for our starting point, for, although the problems of sanitation are very old, the efforts to solve them in a systematic manner and by the aid of science can only be said to have commenced in 1838. From that date till 1854 there was a considerable amount of activity on the part of the public, but it was carried on under a sense of the magnitude of the evils which all recognised rather than with a clear understanding of the proper remedies to be applied. No doubt a considerable amount of knowledge regarding the causes and prevention of disease had been gathered, but it was applied as the result of the pressure of a new ideal of politics and social duty rather than according to the teachings of science. Even the remedies proposed by the Commissioners whose inquiries led to the passing of the Public Health Act of 1848 and the constitution of the Board of Health were administered with more zeal than discretion. Mr. Edwin Chadwick, who directed the policy of the Board, was so thoroughly in earnest himself that he could understand neither ignorance nor apathy on the part of others, and his zeal practically drove him from office in 1854. From that date until 1866 little was done, but the stagnation was more apparent than real. Public opinion was slowly ripening on the subject, and scientific men were collecting a large number of facts, and ascertaining principles, which led in 1866 to a great outburst of legislative activity on sanitary matters. This caused the appointment of the Royal Sanitary Commission, which reported in 1871, and which has had a great effect both on legislation and administration. The principal Acts were those for constituting the Local Government Board (1871), for amending the powers of local authorities (1872), for dealing with Public Health (1875), Sale of Food and Drugs (1875), Pollution of Rivers (1876), Factories and Workshops (1878), Public Health (Interments) (1879), Alkali, &c., Works Regulation (1881), Artisans' Dwellings Improvement (1875–82); and we now have quite a large number of factory and other Bills all dealing with the subject of the sanitary conditions of our workpeople.

On the downfall of the Board of Health in 1854 little official work in sanitary matters was done for some years. The work of the Board was handed over to a single Minister, assisted by a few medical experts, among whom was Sir John Simon, and in 1858 its functions were divided between the Privy Council and the Home Office. Sir John Simon was transferred to the former, and as Medical Officer to the Privy Council he rendered excellent service, and his investigations had a great effect in shaping the Sanitary Act of 1866. Although that Act was mainly permissive, it was largely taken advantage of by the local authorities. It was only compulsory in so far that it declared it to be the duty of every local authority to provide for the inspection and suppression of nuisances, for adequate water supply, and for drainage. Moreover, it strengthened the hands of the central authority, whose officers were required to report on the shortcomings of the local bodies. The functions of the central authority have now been greatly confirmed and extended, for, although the Local Government Board has small powers of compulsion, it has large powers of sanctioning and advising, which are possibly more effective, and the numerous local bodies which have been created under the Local Government Acts have recently been most active. Indeed, medical officers of health and sanitary inspectors now form what are practically two new professions. At first sight, however, the results of all the efforts which have been made seem disappointing. In 1838 the death-rate in England was 22·4 per thousand, while for the ten years 1871–80 the mean annual death-rate was 21·27, and the difference does not seem great. But averages of this sort must be used with great caution, and detailed statistics are required before the real lessons they teach can be clearly ascertained. One rather remarkable detail is the fact that the fall in the death-rate is unequally divided between the sexes, being less for men than for women. Another detail is that this fall is unequally distributed over the various periods of life, and statistics prove that the probability of a man's reaching the age of seventy is smaller than it was, a fact to be accounted for, we suppose, by the high pressure at which we live. The greater attention which is being paid in towns to sanitary matters is making the death-rate in the towns sink faster than in the country, and the difference between the two is rapidly vanishing. For instance, in 1851–60 the death-rate in towns was 24·7, and in country districts 19·9, while in 1888 the towns stood at 18·4, the country at 16·7. The most important decreases on account of sanitary measures are in the deaths due to zymotic diseases. In the decade 1851–60, out of every million inhabitants 4,122 died from such diseases, while in 1888 there were but 1,840. Consumption has also yielded, to a considerable extent, to sanitary efforts, for we find that in 1851–60 the death-rate from consumption for England and Wales was 2·68; in 1888 it was but 1·55, a result which has, no doubt, been brought about by improved draining and ventilation of houses and factories.

The effects of occupations on health have long engaged the attention of doctors and statisticians. Clergymen and farmers are the two classes which seem to live longest. Taking the average mortality of all males at 1,000, the mortality of the clergy is represented by 556, and of the farmers by 631. High in the scale stand brewers with no less than 1,361, innkeepers with 1,521, and butchers with 1,170. Filemakers stand at the high figure of 1,667, cutlers at 1,309, plumbers at 1,202, earthenware makers at 1,742, printers at 1,071, bookbinders at 1,167, tailors at 1,051, and shoemakers at 921. In the great cotton and woollen industries, to which legislation seems at present to be chiefly directed, the figures are 1,088 and 1,032 respectively. In

Digitized by Google

the cotton and linen industries there has been a fall in the death-rate from 10·65 to 9·99 in the first half of the working life of the operatives, and a rise from 27·90 to 29·44 in the latter half, if we compare the returns for 1861–71 with those of 1880–82. In the wool and worsted industries the death-rate has risen in the earlier period of life from 9·35 to 9·71, in the later from 23·26 to 27·50. These figures prove that there is something distinctly wrong in the conditions under which the work is done. In the silk industry, on the other hand, in which dust would be injurious to the material, arrangements are made to avoid it, and the mortality among the workers is low. This fact proves that in the cotton and wool industries a great deal might be done to improve the health of the operatives, and justifies the efforts of those who are urging legislative measures in the matter. It is rather curious to note that coal miners are remarkably free from consumption, and, if it were not for accidents, the average life of coal miners would be fairly good. In the earlier part of their careers the death-rate has fallen from 11·30 to 7·79, and risen in the latter from 22·01 to 24·04. This fact is to be noted in nearly all the chief industries, and seems to prove that improved food and other conditions have given our workpeople greater strength in their early years. Still, there are circumstances which gradually undermine their health, and make their lives, on the whole, shorter than those of the workers of fifty years ago.

THE NAVY ESTIMATES AND OUR NAVAL POLICY.

The statement which has been issued by the Admiralty explanatory of the Navy Estimates and policy for 1890–91, and the subsequent discussion, contain nothing of a very startling nature. Possibly the point which will be most clearly recognised by the long-suffering taxpayer is the fact that there is an increase of the estimates for the year of £428,500. Part of this is not new expenditure, but arises from the transference of duties to the Admiralty from other Departments, the largest item of this nature being £78,000 for naval ordnance stores, which were formerly provided for in the Army Estimates. The account for wages to seamen has been considerably increased, owing to the additional numbers required consisting largely of the mechanic and other highly-paid classes. These additional numbers have, of course, naturally affected the victualling vote, and provision has also to be made in this vote for an increase in the value of stocks of clothing, owing to the introduction of an improved and more costly material for seamen's clothing, recommended by the Committee that has been considering the subject. The amount to be expended in the year 1890–91 on new construction is estimated at £3,146,938 on the Dockyard programme and £3,512,804 on the vessels building by contract, while that for the year 1891-92 is £3,879,119 for the former and £3,547,733 for the latter. An advance in the wages of the workmen employed in Her Majesty's naval establishments at home has been granted, to take effect from the 1st April, and causes an increase of about £78,000 in the several wages votes. Vessels, costing in the aggregate £3,214,294, are expected to be completed and added to the effective strength of the navy during the year ending 31st March.

It is satisfactory to find that good progress has been made with the work being done by contract under the Naval Defence Act during the year 1890-91, notwithstanding various conditions of difficulty arising out of the great activity in mercantile shipping, and the consequent extraordinary demands both for labour and materials. The completion of the five cruisers and the two torpedo gunboats building under the Imperial Defence Act of 1888 has been delayed by the conditions of the market, both as regards labour and material, but the main cause of the delay has been the unusually long period required for the completion of the steam trials of these vessels, and for surmounting the difficulties which have arisen with their boilers. It has now been finally decided by the Board to take over the vessels without insisting upon the completion of maximum forced draught trials embodied in the contracts.

The arrangements which were made for the building of the Australian flotilla have proved completely successful. Having been built under a special Act of Parliament, it was decided that the vessels should be completed in all respects for sea, with the exception of their ammunition and consumable stores, at the works of the contractors, in the hope that delay and cost would thus be avoided in connection with the alterations which not infrequently attend trials of contract-built ships at the Dockyards. The anticipated advantage of this arrangement has been fully realised, and the trials of guns, torpedoes, and propelling machinery have all been carried out and completed before the vessels have been handed over. They will be ready for commission within the financial year 1890–91.

The size of the second-class battle-ships as built will exceed the dimensions of the original estimate. This increase in size has been approved after very full consideration, and arises chiefly from improvements in the armament, sheathing, size of boilers, and other points, which will add not only to their strength, but also to the possible length of their continuous sea service. If these vessels are completed without further demands being made upon them for additional weights to be carried in connection with the armament or equipment, they will be capable of carrying 50 per cent. more coal than was originally intended, and bunker space sufficient to carry this full supply has been provided. The experience gained by the behaviour of the cruisers during the recent naval manœuvres has been taken advantage of, and the original designs of the eight second-class cruisers of the "Apollo" class have been somewhat modified. During the past year a large number of trials have been made with gunboats, but unforeseen difficulties have occurred with the boilers when working at the highest powers intended in the design. These difficulties have been to a large extent overcome, but the maximum power under forced draught originally intended to be developed has not been obtained. The structural strength of the vessels has been severely tested during their long-continued steam trials, and several of them have been launched with machinery and boilers on board. The result has been satisfactory. The question of the modifications to be embodied in the designs for the vessels yet to be ordered is now on the point of being dealt with finally. It is further satisfactory to find that all the ships that were ordered and commenced in the Dockyards before 1889–90 will, with the single exception of the "Blake," be practically completed during this financial year, and this ship will be completed in the year 1891–92. It will yield little pleasure to marine engineers to learn that the steam trials of the past year are mentioned as the least satisfactory part of the work. The difficulties are said to have been overcome, but, as this has been done by reducing the indicated horse-power and the speed of the vessels, the difficulties have been rather shelved than overcome.

The work contemplated by the Naval Defence Act is now sufficiently advanced to enable a forecast to be made both of the date at which it will be completed and of its actual as compared with its estimated cost. The number of ships to be built was 70, of an estimated displacement of 316,000 tons, and carrying 540 guns, exclusive of machine guns and guns of small calibre. The whole of these vessels, with their armament and equipment, were to be completed and ready for commission before the 1st of April, 1894. With the single exception of one contract-built ship, whose progress has been slow, there is every reason to believe that the remaining 69 will, with their armament and reserve guns, be finished before the date named. On the whole, we think that the public have reason to be pleased with the work done during the past year, and also with the proposals for the future.

NEW CUNARD STEAMERS.

We understand that the Cunard Company are about to build two steamers larger and faster than any as yet afloat plying between Liverpool and New York, so that, notwithstanding the progress which has recently been made, the ocean race continues. Many seemed disposed to think that the recent additions to the Inman and the White Star Lines left little to be wished for as regards accommodation and speed, and were content to rest and be thankful with a speed which carried them from Liverpool to New York in a little over six days, but those responsible for shipping arrangements seem to feel that in the matter of speed the proper state should be kinetic not static, and that without advance there is very apt to be retrogression. Little more than thirty years ago, when the Cunard Liner "Scotia," the last of the paddle-steamers on the Atlantic, made the voyage from New York to Queenstown in eight days, the performance was hailed with much satisfaction. Then followed in 1867 the Inman Liner, the first "City of Paris," which beat the "Scotia" as regards speed, and exceeded her in size. She, however, was afterwards beaten by the "City of Brussels" in 1869. In 1870 the "Oceanic," the first of the White Star Liners, gave a further impetus to the race, which was continued by the sister ships, the "Britannic" and the "Germanic." In 1879 a new departure took place when the "Arizona" of the Guion Line in her first voyage easily beat the previous Atlantic record. The Cunard Line at once ordered the "Servia," a steamer of 7,000 tons, and the Inman Line the "City of Rome," which has a tonnage of 8,450. These were speedily followed by the "Alaska," in 1882, which easily beat the best running of both. Then followed the "Umbria" and the "Etruria," in 1885, which soon established themselves as the swiftest steamers on the Atlantic, and they continued to hold their own until 1889, when the "City of Paris," in her second run, excelled them in speed. The "City of New York" and the two new White Star Liners, the "Teutonic" and the "Majestic," are also faster than any of the Cunard Liners. The directors of the latter company have determined to again enter the field, and hope to beat everything that has yet been done both as regards size and speed. The issue will be watched with much interest.

THE MANCHESTER CORPORATION AND THE SHIP CANAL.

The sub-committee appointed by the Manchester Corporation to consider the request of the Manchester Ship Canal Company to assist them in the promotion of their undertaking, have issued their report, and it will be considered at a special meeting of the Council to be held on Monday next. The committee state that they have made thorough and independent inquiry into the position of the undertaking, and have carefully considered reports submitted by their own engineers, and also those of the canal officials. They find that up to December last over £9,000,000 had been spent on the canal, and that £3,900,000 are still needed to complete the work, giving a total expenditure of about £13,000,000. The total resources of the company appeared to be £10,900,000. The committee are of opinion that a sum of £2,500,000 will be sufficient for them to advance, but they are advised that it would be prudent that borrowing powers should be sought by the Corporation for £3,000,000. It is evident, the committee say, that unless most substantial assistance is promptly given the Ship Canal Company by the Corporation of Manchester, or from some other public source, the works must stop. That it cannot raise the necessary funds without such aid appears from the fact that it is unable to get the public to subscribe for £400,000 of debentures, although they are an absolute first charge on the undertaking; and even if the company could, by an energetic appeal, raise this money, there was no time for so doing. At the ordinary rate of working their present funds will not last for more than a few months, and any stoppage of the works will be disastrous, and will probably permanently cripple the usefulness of the undertaking. The difficulties, the committee believe, do not arise from any innate defect in the project, nor do they indicate that the anticipations formed of its success were unfounded. On the contrary, the committee are not aware of any circumstances that have happened since the works were commenced that would give rise to apprehension as to the probable earning power of the canal. In the opinion of the committee the sums advanced by the Corporation must rank as a charge upon the undertaking next after the debentures at present authorised, but in priority to all the shares. The committee believe that the required assistance can be given without any serious risk of throwing any burden upon the ratepayers of Manchester. The assistance should not take the form of a permanent loan of public money or a guarantee of returns, but the Corporation should require the company to issue new debentures on fair terms, which will make them an acceptable security to the public when the canal becomes a productive property; and the Corporation should obtain powers to lend all sums required for the completion of the undertaking, receiving, in return, these debentures at par. The Corporation should sell these debentures at par so soon as the improved credit of the undertaking renders them marketable. The new debentures should be issued at ½ per cent. higher interest than the present ones—namely, 4½ per cent.—and the company should have power to redeem them at par after a short period. They therefore recommend that the Council should render the company the pecuniary assistance requisite to complete the undertaking. Other corporations may join if they desire.

ALUMINIUM AND STEEL.

On the 28th ult. the inaugural lecture under the auspices of the newly-formed Metallurgical Society, in connection with the Sheffield Technical School, was given by Professor Arnold, the subject being "The

Digitized by Google

Application of Aluminium to the Manufacture of Steel and Steel Castings." The Society, anxious to make their first gathering a success, issued special invitations to many Sheffield gentlemen connected with steel making.

Professor Arnold said that the recent literature which had been placed before them respecting the effects of aluminium on steel had been so widely discrepant that he decided, for that lecture, to make experiments of his own and lay them before the public. His researches had been made on different lines to those adopted by Mr. Hadfield, for he thought it would be superfluous to again go over the ground so fully covered by that gentleman. The lecturer then, by the aid of numerous illustrations thrown on a screen, proceeded to explain the various effects of aluminium on steel. He first dwelt upon crucible cast steel, secondly explained "blow-holes," and lastly gave illustrations of steel castings, with and without aluminium. He explained the causes, effect, and cure of "blow-holes" and "piping." The lecturer not only attempted to prove that steel made with the use of aluminium was better than that made without, but also that there was a great saving from a monetary point of view.

In conclusion, Professor Arnold said the metallurgist of the future would have to be a different man from that of the past. He knew in saying that he was going against what was said at the Firth College the other evening by Professor Anderson, the Professor of Classics. In his exposition on art proper, Professor Anderson deprecated technical education, and spoke of it as a tendency to develop the baser mechanical arts. He would say that the baser mechanical arts had made this country what she was, and if she was to maintain her position she could only do so by a vigorous development of these baser mechanical arts. In the future, as in the past, they would have to look to these baser mechanical arts to feed and clothe the toiling millions of our vast industrial empire.

The Chairman announced that the discussion on Professor Arnold's paper would take place at the next meeting of members.

Letters to the Editor.

SIBLEY COLLEGE, CORNELL UNIVERSITY.

To the Editor of "Industries."

Sir,—I see in your issue of January 30th, a very pleasant and appreciative notice of Sibley College, Cornell University, and its related schools of technical instruction, in the course of which the remark is made that "it now holds property and investments to the utmost allowed by its charter." This is an error. It was the fact, until recently, that its charter permitted the holding of only $3,000,000 (£600,000 nearly), but that provision of the charter was repealed by the Legislature of the State of New York—which State founded the University—immediately upon the discovery that it was likely to cause the loss of a bequest, which now proves to have a value of about $2,000,000 (£400,000), and which was left it by the late Mrs. Jenny McGraw Fiske. The University has actually met with this great loss; but, the horse being stolen, the stable door has been effectively locked, which gives us the privilege of receiving and holding, hereafter, any number of millions.

I am also happy to say that this institution, pledged to make its "leading object" for ever the promotion of the useful arts, now has above a million of pounds invested, and so well-placed that its trustees receive an average of 6 per cent., and have never lost a fraction of a per cent. of the principal. It expends about $400,000 a year on its legitimate work, and is now teaching 1,400 students, of whom about one-half are engaged in technical and professional studies. It still finds ample use for all available funds, and its opportunities grow with its magnitude, as in all well-managed enterprises. At the rate of growth that has astonished our friends and embarrassed its trustees and faculty during the last half-dozen years, it can find use for ten millions more during the coming decade. It is not at all unlikely that it may receive them, for it has never yet been compelled to delay a good work for lack of funds. Capitalists, seeking this kind of investment, look for places where their funds are safe and likely to give good returns.

Your readers may be interested in learning what kind of an outfit we consider proper in a course of instruction in the higher branches of mechanical engineering and the mechanic arts, such as Sibley College was organised to give. We shall have, at the close of the current, or at the beginning of the coming collegiate year, about $200,000 in equipment. It will include an "experimental steam engine" of about 200 horse-power triple-expansion, with Corliss valves, adjustable in all possible ways to enable us to make investigations of the effects of varying ratios of expansion from 0 to unity, varying steam-pressures from 2 to 15 atmospheres, varying speeds from a minimum to probably 200 revolutions a minute, and all desirable adjustments of steam and exhaust valves for other purposes. The jackets are piped separately; steam and exhaust eccentrics are fitted for operation together or independently; the engines themselves can be worked together or independently, combining a simple set of engines, compound or triple-expansion, as may be desired. A number of other engines—steam, gas, and hot-air—are used in the regular course of laboratory instruction, a collection of dynamometers, steam-boiler injectors, hydraulic apparatus, and a great variety of testing machines, including—standing in a row—one of 50, one of 100, and one of 150 tons capacity, and a number of smaller ones of various types and sizes. With such an outfit, we handle 200 students in the laboratory, having 450 (nearly) in all classes, including graduate students engaged in research

Yours, &c.,
R. H. Thurston, Director.

THE INSTITUTE OF CHEMISTRY.

To the Editor of "Industries."

Sir,—Having been entrusted with the privilege of assisting in the auditing of the accounts of the Institute of Chemistry, I cannot refrain from correcting the false impression that is likely to be caused by the concluding paragraph of the first part of your article on the Institute of Chemistry. From this it would appear that the salaries of the secretary and of his clerk were the sole payments made by the Institute. As a matter of fact, however, the total amount paid for salaries and wages during the year was only £178. Of the chief item of expenditure—examination expenditure—you make no mention. This is decidedly unjust, as the Institute is primarily an examining body, and practical examinations are held at six centres at considerable expense.

In these days of technical education it is surprising to see a journal of such standing as yours advocate the replacement of theoretical training by the almost extinct process of apprenticeship. The slightest acquaintance with the laboratory of an analytical chemist renders evident the unsatisfactory character of the education to be obtained there. Day after day there is the same class of work, and the pupil finally becomes an accomplished analyst of manures, or salt-cake, or stomachs, or whatever may be the substance he has daily examined, without being able to conduct a simple qualitative analysis. Compare this with a well-organised course of instruction as given in the laboratories of our universities and technical schools.

Your proposals for the enhancement of the usefulness of the Institute are, I consider, thoroughly unsatisfactory. With a council composed of residents in London, the Institute of Chemistry of Great Britain and Ireland would acquire a parochial character, and, with the other changes you suggest, you would convert the Institute into a trade union existing with the object of extorting premiums from the confiding parents of aspiring analysts.

Yours, &c.,
Bennett H. Brough.

London, 28th February, 1891.

To the Editor of "Industries."

Sir,—I have read your two articles on the Institute of Chemistry. To borrow a phrase from Carlyle, the articles in question contain some things which are near the mark, others further from the mark, and others altogether far away from any mark. In the first category is the suggestion for converting the profession of chemistry into a close corporation; in the second, the not too exact comparison between an examining and qualifying body like the Institute of Chemistry, and a learned Society such as the Institution of Civil Engineers. The latter society is on all fours—not with the Institute of Chemistry—but with the Chemical Society. Altogether far away from any mark is the strange suggestion that the representative of "scholastic and collegiate chemistry should be welcomed as guests, and, if of sufficient eminence, admitted as honorary members, but should have no voice in the management of its (the Institute of Chemistry's) affairs;" and also the equally strange idea that "there is a considerable number of professional chemists, many of them men of the highest eminence and commanding ability, who have not a shade of a notion of the accuracy, originality, technical knowledge, and executive faculty absolutely essential for a successful consulting chemist, and who would be as incompetent to do his work, or even understand it, as he theirs."

The writer of this article, when he penned the former of these two paragraphs, could hardly have been aware that the Institute mainly owed its foundation to those "scholastic and collegiate" chemists of whom he speaks so disparagingly, or he would possibly have hesitated to suggest so striking an application of the principle of "*Sic vos non vobis.*" Altruism has its limits.

The second paragraph unavoidably suggests the inference that these articles were not written by a chemist—or, at any rate, not by a chemist who views his profession as a science, and recognises the subordinate position which routine work holds, and always must hold, in relation to scientific research. The "scholastic and collegiate" chemists, whose acquirements are here so summarily dismissed, would be found competent to perform the work of a "successful consulting chemist" at a moment's notice, and with the utmost efficiency, whereas the converse of this proposition by no means holds.

You are right in maintaining that the Fellows should have more power, and the Council less; in error, in your desire to substitute an exclusively "practical" (*i.e.*, artisan and rule-of-thumb) training for a comprehensive and scientific one; right, in attacking the monopoly of training possessed by a few rather hastily-chosen collegiate bodies; right, in reminding the Council that it is time to be up and doing; and wrong, in viewing the Institute merely as a hall-marking trade machine, and not as an engine for the education and approbation of the votaries of a noble science.

Yours, &c.,
Bryan Charles Waller, M.D., F.R.C.S., F.I.C.

MR. KAPP'S CANTOR LECTURES.

To the Editor of "Industries."

Sir,—The Secretary of the General Electric Power and Traction Company, Limited, has sent you last week for publication two of the letters which have passed between me and his company, but he omitted to send you copy of a letter which I had previously written to the company, and which I now append. Any of your readers seeing only the two letters selected by the Secretary for publication must naturally come to the conclusion that the immediate cause of my withdrawing certain figures was the Secretary's letter, and that his hint about legal proceedings may have had something to do with it. This was, however, not the case, as your readers may see from the enclosed copy of a letter I wrote to the company a day before I received their letter. To this letter the company made no reply, and also ignored it when sending some of the correspondence to you. I now ask you to publish it in order to dispel the impression that I had to be asked to do that which any fair-minded person would naturally do of his own accord.

As regards the general question of personal responsibility for figures given in a lecture, I would point out that a lecturer is expected to give his own views, and to do this on his own responsibility when the matter under discussion relates to theory or experiment, or any other question which he can test for himself, but that he cannot take this responsibility in matters which he cannot test for himself. All that can be required of him in such cases is that he shall take reasonable precautions to obtain the most reliable information possible, and then give the information, citing his authority. This I have done. Whenever the company or their predecessors invited me to inspect their work, I found Mr. Frazer in chief command, and even last summer, when taking part in the visit of the Electrical Engineers to the Edinburgh Exhibition, I found Mr. Frazer acting as cicerone. It was therefore perfectly natural that I should apply to him for information, and give the figures supplied by him on his authority. It would have been an absurd presumption on my part had I attempted to criticise or alter the figures given me by so high an authority in traction business as Mr. Frazer is, and therefore I put them into my lecture exactly as he gave them. On the other hand, when I discovered that the company repudiate these figures, it would have been equally presumptious to argue the matter with them, and I was therefore equally ready to substitute the company's figures. If the company supply me with their correct figures, I shall insert them on their authority when the lectures are printed; if not, the two tables in dispute must be left out altogether.

Yours, &c.,
Gisbert Kapp.

3rd March, 1891.

[Copy.]

Messrs. The Electric Traction and Power Company, Limited,
Maldon Crescent, Prince of Wales Road, Kentish Town.

Dear Sirs,—I was surprised to hear last night from Mr. Snell that he considers the figures I gave in my Cantor lecture with reference to the Barking Road tramway incorrect. When towards the end of last year I applied to Mr. Frazer for information about the working of battery cars, I was under the impression that this gentleman was the member of your company who had the entire control of your traction work, and I therefore took the figures which he gave me as authentic and correct. If, however, as Mr. Snell asserted last night, the figures are not correct, it appears desirable that the necessary corrections should be made in the tables I gave at the Society of Arts lecture; and I shall do this if you will kindly supply me with the exact figures.

Yours faithfully,
Gisbert Kapp.

Erba, Wimbledon, February 20, 1891.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—As Mr. Lovett refers to my letter which you were good enough to publish in a recent number of *Industries*, you will, I trust, allow me a few lines for reply.

Mr. Lovett says that such gas stoves as he has tried lack radiating power, and considers that the vice to which they are most prone is a tendency to discharge their products of combustion into the air unless these products be allowed to escape at so high a temperature that much waste results. I freely admit that many gas stoves possess these defects, but that all do is, I think, scarcely to be asserted. Taking the accusations against them, we have, first, their supposed want of radiating power. This, I believe, is largely caused by the selection of a refractory substance unsuitable for its office. Considerable search has been necessary to find a "best" material. The monstrosities in platinum wire, asbestos, and the like are still fresh in our memories, and their delinquencies have condemned their more worthy fellows. Nowadays better things are to be had. Asbestos rightly disposed, iron frets, and, lately, perforated fireclay balls, have displaced them for good. Those who have been scorched by the little gas fire that serves to warm my balance room would, I am sure, testify—were it necessary—to the improvement there has lately been in such matters.

Next, as to the discharge of the products of combustion into the room warmed by the stove. It occurs sometimes on lighting the fire, because the flue is cold, but provided this be really efficient, the trouble will disappear as it gets warm. The same condition—viz., the efficiency of the flue, determines whether the burnt gases shall escape at a temperature unnecessarily high. Secure a good flue, and either let a portion of it be in the room to be warmed, or use instead a gas fire, the body of which, as well as the actual grate, serves as a source of heat, and there will be little cause for complaint. Too great economy of gas, resulting in robbing the products of combustion of all their available heat, will bring its own punishment in the shape of a sluggish draught.

Stoves that embody these points are, no doubt, made by several firms, but the one of whose goods I happen to have most experience is that of T. Fletcher & Co., and Mr. Lovett could doubtless obtain specific information from them. One more word, sir, and I have done. There has been still no proposition made as to the means by which the scheme is to be financed. I trust Mr. Thwaite or some other correspondent will give us the benefit of his views on this part of the subject.

Yours, &c.,
B. B.

London, 2nd March, 1891.

THE MANCHESTER SHIP CANAL.

II.

In continuation of our description of this interesting work, we publish on page 228 a view of the Moore Lane swing bridge and of the viaduct over the River Irwell in Deviation Railway No. 5.

Fig. 3 shows the viaduct over the River Irwell, carrying the deviation line No. 5 to take the traffic of the Cheshire Lines Committee between Liverpool and Man-

Digitized by Google

chester, at a point between Flixton and Glazebrook. It carries four lines of way, and is constructed of brick arches, with blue brick face and Bramley Fall stone quoins and voussoirs. The girders of the bridge crossing the canal are of steel, and of the ordinary lattice girder type, the flooring consisting of cross girders and longitudinal rail bearers.

The Moore Lane swing bridge, shown in Fig. 4, crosses the canal at a point a few miles below Warrington, and may be taken as typical of several other bridges along the route. The superstructure is now very near completion, but the illustration shows the work as it appeared last June, with little more than the roller path attached. The bridge is 238ft. long, divided in two arms of 140ft. and 98ft. long respectively, the longer arm spanning the canal, and the shorter or tail end spans the slope of the bank. The width of the bridge is 25ft. between the main girders, giving a roadway between the kerbs of 19ft. 6in., with a single footpath 5ft. wide. The girders are 27ft. 8in. deep at the centre over the angle irons, the depth of the short end being 8ft. 9in., and the long end 6ft. The booms are 2ft. 3in. wide, of the ordinary trough shape, the verticals being 24in. by $\frac{1}{2}$in. thick, and the angles 6in. by 6in. by $\frac{5}{8}$in. The whole weight of the structure is about 580 tons, and in addition to this is the kentledge, in the shorter arm weighing 120 tons. With the exception of the floor-plates the structure is of steel throughout. The booms are stiffened at the centre of the bridge to maintain the extra stress when swinging; the plates consisting of two $\frac{1}{2}$in. plates and one $\frac{9}{16}$in. plate, the latter running the whole length of the girder. The vertical plates are increased to 3ft. deep, connected at the top with an inch plate by means of angle irons, 6in. by 6in. by $\frac{5}{8}$in. The ends of the girders are closed by means of $\frac{7}{16}$in. plates. The cross girders are spaced 14ft. apart, and are 2ft. 9in. deep in the centre over the angles, and are attached to the vertical struts of the main girders by angles 8$\frac{1}{2}$in. by 4in. by $\frac{1}{2}$in. Six longitudinal road beams are fixed to the webs of the cross girders, and these in their turn receive angles, and the whole is then plated with buckle plates $\frac{3}{8}$in. thick. The plates are covered with asphalte $\frac{3}{4}$in. thick, then an inch layer of sand, on which are placed the 5in. wood sets to form the roadway. The shorter arm, which contains the kentledge, consists of an iron box girder and three kentledge girders, 3ft. deep above the angles, securely fixed to the main girders. Under the centre of the main girders are fixed four heavy web girders, 3ft. 6in. deep at the centre and 2ft. at the ends, each having three webs, stiffened by plates and angles. The kentledge forms the paving at the shorter end, no wood sets being necessary. A circular girder, 2ft. 11$\frac{1}{2}$in. wide, is fixed under the centre bearing girders, 2ft. deep, and with two webs. This girder carries the cast-iron upper roller path, which has four arms fixed to the bridge centre by means of a cast-iron collar. The bridge turns on live rollers 2ft. 5$\frac{1}{2}$in. long and 15in. diameter at the centre, the pressure per lineal inch on the rollers being calculated at 800lb. The lower roller path is attached to the granite stones of the pier. The pier consists of Portland cement concrete foundation, in the proportion of 8 to 1 inside and 4 to 1 on the face, up to water level; above this level the inside is of brick, with blue brick face, a granite fender course, 18in. deep, being fixed between the concrete and the brickwork. The bridge is actuated by means of three-throw hydraulic pumps, made by Sir W. G. Armstrong & Co. The bridge can also be turned by hand if necessary.

THE INSTITUTION OF CIVIL ENGINEERS.

At a meeting of this Institution on the 3rd inst., the President, Sir John Coode, K.C.M.G., being in the chair, a paper was read "On the Subterranean Water in the Chalk Formation of the Upper Thames, and its Relation to the Supply of London," by Mr. J. Thornhill Harrison, M.Inst.C.E.

The author stated that the question of the supply of water to London from the chalk formation had on several occasions been discussed at the Institution, and that at least two schemes with this object in view had been unsuccessfully promoted in Parliament, the cause of failure in each case being identical—namely, the fear that the volume of the water in the rivers, deriving much of their supply from the chalk, would be largely diminished, to the serious injury of persons interested in such streams. By reference to the Report of the Royal Commission on Water Supply, 1866, and to the opinion of Dr. Evans, the author showed how strong were the fears of this character entertained by persons who had studied the subject, and stated that unless apprehensions of this nature were shown to be groundless, and unless he was prepared to give convincing proofs that no such injuries would be caused to rivers by the proposed abstraction of water from the chalk, it would be useless to bring forward the present paper. The author's intention was, therefore, to show not only that the Upper Thames chalk basin could afford the requisite water supply in abundant quantities, but also that the necessary volume might be safely withdrawn without detriment to the Thames or to any of its tributaries.

Before dealing with the question of quantity, the experiments of the late Professor Ansted were cited, and the distinction made by him between the upper or flint-bearing chalk, and the darker coloured lower chalk, or clunch, was explained. These latter beds, which were capable of holding much more water than the upper chalk, surrounded the valley of the Thames, and formed, by upheaval, the lofty ridges encircling the Thames basin. One square mile of dry upper chalk 1 yard thick contained nearly 3,500,000 gallons of water, and, when saturated, it held 200,000,000 gallons; while the same area and depth of lower chalk, when dry, held 12,000,000 gallons, and, when saturated, 180,000,000 gallons of water. The water in the chalk was probably conveyed to the point of issue by means of fissures, and these fissures, no doubt, accounted for the convection of the chalk water from the neighbourhood of Devizes to the Thames, between Wallingford and Streatley, a distance of 40 miles. Dealing with the relative proportions of the rainfall which sank into the chalk and the amount evaporated from the surface or absorbed by vegetation, the observations of Messrs. Lawes and Gilbert, of Mr. Greaves, and of Messrs. Dickinson and Evans were discussed, and it was pointed out that while Mr. Dickinson had found that out of a rainfall of 27·843in., 10·65in. passed through 3ft. of chalk, Sir J. B. Lawes and Dr. Gilbert had observed that out of a mean rainfall of 31·451in., during the years 1871 to 1880, 14·04in. passed through 20in. of soil and 13·241in. through 60in. In order to practically test these results, a series of actual measurements of the rainfall and of the discharge from a large area of the chalk would be advisable. In the absence of such statistics, in order to form an approximate estimate, the Wandle basin, with a drainage area of about 56 square miles, was selected. From observations by Mr. Braithwaite on the flow of the Wandle, the mean volume discharged from the above area was stated by the author to amount to 30,000,000 gallons per diem, which was equal to 13$\frac{1}{2}$in. of rain falling annually on 56 square miles. This depth was fairly in accord with the previous computations, but it was exceeded by the estimate formed by the late Professor Ansted, who considered that at least 18in. out of a mean annual rainfall of 26in. in the East of England were received into the mass of the rock. Proceeding to apply these data to the chalk basin westward of London, the daily discharges from the principal rivers were first calculated; these were assumed to be:—

From the Thames, Kennet, and Wye	150,000,000 gallons.
From the Colne and Lea.....	100,000,000 „
Total	250,000,000 „

These rivers discharged the surplus water from an area of about 1,200 square miles, and the above volume represented an annual rainfall of about 5in. There remained then, on the basis of Mr. Dickinson's experiments, about 5$\frac{1}{2}$in. still to be accounted for, or according to Messrs. Lawes and Gilbert's experiments, and the estimate based upon the flow of the Wandle, about 8in. of the rainfall which was not discharged by the ordinary channels, and the question presented itself, What became of this water? Mr. Homersham had suggested that large volumes of chalk-water, which he deemed equivalent to a daily supply of 408,000,000 gallons, at present escaped into the sea, but the author affirmed that in consequence of the existence of the great fault across the London basin, south of the Thames, this egress to the sea was barred. From a geological consideration of the London basin, he concluded that the only escape for this water seawards was over the surface of the London clay at Datchet, near Windsor, where that clay was at an elevation of about 47ft. above ordnance datum, being there covered with a bed of gravel 12ft. in thickness and 1 mile in width, the clay stratum constituting a species of weir. This gravel bed was stated to be in the nature of a great reservoir; it extended from Datchet westward to Maidenhead, overlying the lower tertiary beds and the chalk, and attained in places a thickness of 30ft. The water in this bed did not depend for its supply on the Thames, but, on the contrary, it added to the volume of the river as it passed by. The amount of water it contributed to the Thames was shown, by gaugings, to vary from 137,000,000 gallons per diem to 17,000,000 gallons, and these fluctuations were probably due, as was pointed out, to the regulation of the water level in the river by the weirs. After entering this vast gravel bed, with an area of some 40 square miles over the unalterable weir at Datchet, the water from the chalk, according to the author, found its way, by hidden springs, into the Thames between Maidenhead and Thames Ditton, causing an increase in the volume of the river, which varied according to gaugings taken at different dates, from 249,500,000 gallons per diem in April, 1884, to 45,000,000 gallons daily in November, 1890.

Attention was next directed to a second gravel bed, lying to the north of the London clay barrier between Slough and Kingston, which covered an area of about 50 square miles between Burnham on the west and the eastern part of London. This bed also formed an extensive reservoir and an underground river, by which a large volume of water was carried to the Thames. This gravel was crossed by the river nearly at right angles between Kingston and Brentford, where it was for the greater part of the distance an open tidal stream without locks, and the water could thus pass from the gravel into the river at all times, except when the tide was up. Between Teddington and Kew the volume of the Thames was largely increased; the increment amounted to little short of 440,000,000 gallons daily in a dry season, and the author argued that from this source alone a daily volume of 100,000,000 gallons might safely be withdrawn for the supply of London and its suburbs for centuries to come, without interfering in any way with the volume of water which was collected and carried by the Thames between Maidenhead and Teddington. If this supply were adopted the present daily withdrawal of 100,000,000 gallons from the Thames at Hampton might be discontinued. By observation of the level of springs in the chalk about Marlborough it was shown that at Christmas, 1890, the level of the water in the chalk-downs was upwards of 400ft. above the outlet over the London clay at Datchet. The author estimated the area of the collecting ground for the Windsor reservoir at 630 square miles, and that of the Slough reservoir at 570 square miles. Various methods were pointed out for intercepting these underground waters before they passed into the river. The ultimate choice of the Slough or the Windsor gravel beds for the source of the London supply would depend upon which of the two proved to be better in quality. If the water from the Windsor reservoir were to be preferred, the author stated that a scheme suggested by him in 1884 for its collection and carriage to London might be adopted with certain modifications. In this case the water abstracted at or near Dorney would have to be replaced by an equal quantity taken from the Slough reservoir and discharged into the Thames above Windsor.

Three schemes were propounded by the author for the interception of the water forming the underground river in the Slough gravel; of these he stated that the cheapest would be the construction of a culvert in the nature of a dam in a northerly direction from Hampton to Cranford. To this culvert the water would be admitted under control, but the surplus water would be allowed to flow over it at a lower level than that at which it at present stood in the gravel. The other methods were also in the nature of collecting culverts, passing either from Salt Hill to Farnham Royal or from Uxbridge to Langley Marsh.

Reviews.

Practical Notes for Electrical Students. By A. E. Kennelly and H. D. Wilkinson. "The Electrician" Printing and Publishing Company. 1890.

This book, as is stated in the preface, consists mainly of a reprint of a series of articles which appeared in the *Electrician* under the title of "Letters for Learners and Unprofessional Readers." The object of the authors has been to produce a simple practical treatise, requiring no greater mathematical acquirements on the part of the reader than a knowledge of simple equations and of the simple trigonometrical functions. The authors are to be congratulated upon the manner in which they have carried out their programme, and their work will be of value to many who are engaged in the electrical industries, and are precluded, either from want of time or from the lack of a mathematical education, from seriously attacking the theory of the subject. One very valuable

Digitized by Google

feature of the book consists in the frequency with which numerical illustrations of a really practical character are introduced. Bearing in mind the class of readers whom they are addressing, the authors avoid as far as possible the use of mathematical symbols, replacing them by actual numbers taken from some practical example. Another good feature is that the illustrations are thoroughly up to date, and are not mere reproductions of antiquated forms of apparatus.

After a few introductory remarks, an excellent summary is given of the requirements of a good primary battery, and this is followed in Chapter II. by a critical discussion of the chief primary batteries in common use. The statement made in this chapter that the e.m.f. of a Clarke standard cell at 66° Fahr. is 1·45 volts is not correct, except with the qualification that the volts are B. A. volts. The value in true volts is 1·35. Chapter III., on E.M.F. and Potentials, is rather brief, but the graphical treatment of the subject makes it exceedingly clear as far as it goes. The next two chapters deal with resistance and current respectively, and these are followed by three chapters on current indicators, their use and calibration. These chapters are full of useful hints and practical details, and students of much wider acquirements than those for whom the book is primarily intended may derive considerable benefit from their study.

Considerably more than half of the present volume is occupied by the concluding chapter—on Magnetic Fields and their Measurement. In this chapter graphical methods are again very freely employed, with great advantage. The lines of force in various simple cases are illustrated by means of iron filing diagrams. The comparison of the intensities of magnetic fields and of the strengths of poles of magnets are then considered, and the construction and use of a simple form of magnetometer are explained in detail. A very good summary, both of Hughes' and of Ewing's investigations, are given in this chapter.

THE "SHIPPING WORLD" YEAR BOOK. Edited by Evan Rowland Jones, United States Consul. 1891. London: Office of the *Shipping World*.

The fifth issue of the *Shipping World* Year Book is every whit as valuable as its predecessors. The "Port Directory," carefully brought down to date, alone renders it an almost invaluable companion to the master of any ship, but especially of the ocean-going "tramp," as well as to the shipowner. The section devoted to tariffs of all nations is perhaps fuller and more reliable than any similar annual list. Its use to exporters is very obvious; they may obtain from it, in a few minutes, information which extensive correspondence might be necessary to elicit from a number of consuls. The digest of the Shipping Acts, the condensed report of the Load Line Committee with the tables of freeboard, and many other tables—useful alike to shipowner and ship captain—show that the publication is maintaining the high standard set in the issues of past years.

THE MARINE ENGINEER'S ANNUAL AND ALMANAC FOR THE YEAR 1891. Liverpool, Glasgow, and Greenock: D. McGREGOR & Co.

This annual is really an excellent shillingworth. It is packed with matter well brought up to date and extremely useful to the practical seagoing engineer. It contains the regulations relating to the examination of engineers, the Board of Trade rules, and a great quantity of official and scientific information. Several of the most valuable papers read during the year to the professional societies are given in full abstract, and notices are given of the chief novelties in marine engineering and of large new steamers launched during the past year.

THE CALCULATION OF THE E.M.F. OF SIMPLE VOLTAIC CELLS.

By DR. OLIVER LODGE, F.R.S.

I HAVE been often asked by the Editor to write concerning the calculation of the electromotive force of voltaic cells from thermo-chemical data.

It is pretty well known now that the power, or activity, or rate of expenditure of energy, of an electric current is EC.—in other words, is equal to the current multiplied by the e.m.f. which drives it; also that the chemical action going on in a cell per second is proportional simply to the current flowing through it; while the energy of that same chemical action can be, and in many cases has been, measured by determining the heat evolved when the process is conducted in a suitable calorimeter. Given these facts, it follows at once, what was pointed out by Sir W. Thomson in 1851, that the e.m.f. of a cell is a calculable quantity. It is, indeed, simply the number of gramme-degree heat-units produced by the actual chemical action occurring among a gramme-equivalent of the materials, divided by 48,000. This expresses it in volts direct.

But then, as Sir William did not forget to point out, this is the resultant and actual e.m.f. of the cell only in case there are no other sources of energy available to it beside the chemical action. It is the e.m.f. of the cell in so far as that is due to chemical action. It does not, for instance, give us the e.m.f. of a dynamo or of a thermopile. Neither does it give us the entire e.m.f. of anything which partially behaves as a dynamo or a thermopile. If the cell draws upon chemical action alone for its energy, then its voltage is as stated—viz., the thermal value, per dyad-gramme-equivalent, of its total chemical action, divided by the number 48,000. But if it draws also upon motion across magnetic fields, which is unlikely, or upon unequal distribution of heat, for its energy (positive or negative), then, of course, there is an additional e.m.f. to be taken into account, and the resultant voltage of the cell will be the algebraic sum of the components.

Now, wherever there are junctions we are liable to find these extra electromotive forces, not due to any chemical action occurring there, but deriving the necessary energy from heat only; so that some junctions may cool themselves, utilising their heat energy in propelling the current, while others may heat themselves, opposing the current with a corresponding e.m.f. In a galvanic cell are many such junctions, some metallic, on which it is comparatively easy to make experiments, with the result of finding that they are almost inert; others liquid or liquid-metal, on which precise quantitative experiment is extremely difficult. Whether these are also approximately inert, or whether they are, as thermopile junctions, very active, may however be judged by some simple observations, such as the following. Interpose a metal diaphragm in any given liquid after the manner of a porous cell, and pass a current through it. Insert thermometers, one near each face of the metal, and observe their indications. One face (or junction between liquid and metal) will often be found to get hotter, the other, perhaps, to get cooler—precisely what happens when a current is sent through a thermopile; proving the existence of a helping e.m.f. at the cooling junction, an opposing e.m.f. at the heating junction. As an example, the well-known case of zinc or tin may be quoted (Faraday, Exp. Res. 1027, 1028), where the heat appears, not on the side where the metal is being dissolved away, but on the other side, where hydrogen is being liberated, and where one would have thought that, since chemical combination is being here undone, absorption of heat ought to result. It is just because chemical and thermal effects are thus mixed together at metal-liquid junctions, that it is so difficult to disentangle them experimentally, though Bouty has made an energetic attempt to do so.

To be able to predict the behaviour of any given cell, and to calculate its e.m.f. completely, it is not indeed necessary to know what is going on at every separate junction; it is sufficient to take them all together, and to ascertain what the total evolution or disappearance of heat is at the whole lot of junctions together during the passage of a unit current for a unit time. In other words, we must measure, if we can, the heat reversibly evolved or absorbed by the cell during the passage of a unit quantity of electricity through it. That is, we must determine $\frac{dH}{dQ}$, the ratio of the heat evolved to the quantity of electricity conveyed.

This we may suppose likely to be done by stirring the cell and determining its temperature before and after a given production of current for a known time. Only then we should get mixed up the irreversible or frictional generation of heat, as well as the still more disturbing energies of chemical reactions. But fortunately Helmholtz has pointed out that in all reversible heat effects the second law of thermodynamics may be called to our aid, and a cell which behaves in this thermal manner may be treated like a heat engine.

For, just as the main theory of ordinary mechanical heat engines is contained in the statement that the work done in an infinitesimal cycle is

$$dp\,dv = J \cdot \frac{dT}{T} \cdot dH,$$

where $\frac{dT}{T}$ is the efficiency of the engine and dH is the heat carried from the source during the expansion dv, and where dp is the change of pressure appropriate to the change of temperature dT in the working substance; so also with an electrical heat engine, the work done in a cycle by it is

$$dE\,dQ = J\frac{dT}{T} \cdot dH,$$

where dH is the heat conveyed from the source during the passage of a quantity of electricity dQ, and where dE is the change of e.m.f. appropriate to the change of temperature dT. Thus, then, in order to determine $\frac{dH}{dQ}$ which we saw was the quantity needed to be known before e.m.f. can be predicted, it is sufficient to make obervations on $\frac{dE}{dT}$, the rate of change of e.m.f. with temperature. For, from the above equation,

$$\frac{dH}{dQ} = \frac{T}{J} \cdot \frac{dE}{dT},$$

T being, of course, absolute temperature, and J the mechanical equivalent of heat.

Now, whether the e.m.f. of a cell increases or decreases with temperature is a thing very easily observed, and its rate of change is easily measurable. A Daniell scarcely changes at all. Its e.m.f. is nearly constant at all temperatures. For, though the difference of potential at one of its junctions increases with temperature, that of the other decreases almost as much, and there is nearly a balance; as was shown, I think, by Clifton, or by Ayrton and Perry.

But with Clark cells, or with Leclanché, this is by no means the case; the e.m.f. varies with temperature very appreciably (decreasing as the temperature rises in the case of Clark's), and accordingly a thermometer is inserted in all Clark's cells intended to be used as standards of e.m.f.

Cells, then, which have a positive or negative value for $\frac{dE}{dt}$ will have a corresponding value for $\frac{dH}{dQ}$; in other words, they will cool or heat themselves when they produce a current. They act in a manner like thermopiles as well as like chemical cells, and derive their energy from heat as well as from chemical action. To the value of their chemical e.m.f., as already calculated, another term, the thermal e.m.f., has to be added or subtracted—viz., the thermal energy consumed during the passage of a unit quantity of electricity, that is $J\frac{dH}{dQ}$. This quantity $\frac{dH}{dQ}$ is sometimes written $\Sigma(\Pi)$, meaning the algebraic sum of all the Peltier effects occurring in the cell, and its value as opposition e.m.f. is simply

$$T\frac{dE}{dT},$$

the units being the same as those in which the change of e.m.f. dE is expressed. Naturally, they will be volts.

So the whole expression for the calculated voltage of any galvanic cell whose e.m.f. varies with temperature is, at any temperature t° C., writing θ'' for the thermal value of its chemical action expressed in water-gramme degrees per dyad-gramme equivalent—*i.e.*, per 16 grammes of oxygen, 65 grammes of zinc, 2 grammes of hydrogen, 216 grammes of silver, &c.—

$$E = \frac{\theta''}{48000} - (274 + t)\frac{dE}{dt}.$$

The difficulty often felt about the e.m.f. of simple voltaic cells, when considered from the purely chemical point of view, now disappears. Consider some single fluid cells, with the elements respectively, say, zinc and platinum, zinc and copper, zinc and tin, or even zinc and zinc. In each case zinc is dissolved at one side and hydrogen evolved on the other. There is no difference whatever in the chemical reactions; therefore, on merely chemical grounds, it might be supposed that the e.m.f. of each—*i.e.*, the energy imparted by each to the current—was the same. But of course, in fact, they are entirely different, varying from well over a volt to zero. The reason is plain. At the surface where zinc is being dissolved very little heat effect occurs; it is at the other plate (that against which hydrogen is liberated) that the main thermal action is to be looked for. At the platinum surface, while clean, there is not much heat evolved; hence there is a minimum of obstruction here, and a maximum of resultant e.m.f. altogether. At a copper surface there is more heat, at a tin more still, and at a cathode zinc surface there is most. Hence in these cases the cell heats itself during the passage of a current in the natural direction (cooling itself if a current were driven the other way, as through a charging storage battery), and the energy of this reversible heat is obtained at the expense of the current-propelling force. The resultant e.m.f. of the cell is therefore the less as the reversible heat evolution is more. Moreover, as has been shown, the e.m.f. of such cells will decrease with temperature, and the rate of decrease affords the easiest *experimental* method of determining how much of the e.m.f. is chemical and how much is thermal.

The question is often raised as to whether all the chemical actions occurring in a cell are available for

Digitized by Google

propelling the current, or whether a distinction must be drawn between "adjuvant" actions, such, for instance, as the combination of zinc with oxygen, and "non-adjuvant," such as perhaps the solution of zinc oxide in acid.

All such questions can in general terms be answered thus:—Whatever be the chemical action that occurs, it must either liberate some energy or not. If it does liberate energy, this energy has to be accounted for. Either it takes the form of heat on the spot or it does not. If it does not, it must help to propel the current; it must, in fact, be transferred to the current, which accordingly gains energy at the rate EC. If, on the other hand, it does result in heat on the spot, then of course it cannot at the same time propel the current. It can only alter the distribution of temperature of the cell and act in a thermal manner, like the evolution of heat in a thermopile would act, behaving differently according to the locality in which it is liberated.

Attention must, however, be paid to the words "on the spot"—*i.e.*, the spot where the specified chemical action occurs. Now the main chemical action undoubtedly occurs at the surface of the dissolving zinc plate, and whatever heat is *there* produced is not available for propelling the current; but, so far as I know, there is no experimental ground for asserting the appearance or disappearance of any notable quantity of heat at this precise place. If that be so, then *all* the chemical action goes to propel the current.

If heat appears somewhere else, that means that the current is being there opposed, but it does not mean that it has not at one place received the full propulsion due to the complete chemical reaction. If cold appears somewhere else, then that means that the current is being there assisted by an extra or thermal force; and there are cells which cool themselves bodily during the passage of a current. Such an action at first sight appears paradoxical, and contrary to the second fundamental principle of thermodynamics; but it is to be remembered that the action does not go on "automatically" or "unaided." The main propulsion is accomplished elsewhere, at the expense of a quantity of chemical energy, and whether some heat energy is able to assist or to oppose the main force is a mere accident of sign, depending on the direction of the current. It is as when, a submarine tunnel having, by great expenditure of other energy, been made, water is enabled to do work by falling below the sea level, contrary to its usual habits.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At a meeting of this Institution, held on the 26th ult., Mr. Swinburne's paper on "Transformer Distribution" was discussed. An abstract of this paper is concluded on page 224 of our present issue.

Mr. Esson said the discussion on Mr. Mordey's paper left things in a very unsatisfactory state, for no figures were given by which the offered explanation of the experiments could be confirmed or confuted, and at the close of the discussion the author himself admitted that some self-induction was necessary for successful parallel working. Speaking of Mr. Swinburne's armature-reaction theory, he said Dr. Hopkinson included armature reactions in his term "self-induction," and remarked that it would be difficult to deal with self-induction as exhibited by alternators without including these reactions. On the subject of transformers he remarked that the true efficiency was the ratio of the useful energy supplied by the secondary during lighting hours to that put into the primary in the twenty-hour hours, and that upon this ratio the efficiency of the system mainly depends. Coming to the examination of Mr. Swinburne's figures for the efficiency of the closed circuit type, he found this efficiency rather understated. He thought all would agree that it is of great importance to make the "all-day efficiency" as high as possible, but he doubted whether Mr. Swinburne took the best way of doing this.

Mr. Mordey said he did not propose to touch upon the first part of the paper, and would confine himself to one definite subject. On alternators he did not at present wish to add anything to the practical contribution that two years ago he had given to the study of the subject. On many of the minor points of distribution he agreed with Mr. Swinburne's conclusions. From its present interest he thought the design of transformers was the most important subject dealt with in the paper, and to that he would confine himself. The author had arrived at his present conclusions by a zigzag path, as was seen by a reference to the Journal for 1888, in which appeared Mr. Swinburne's remarks in the discussion of a paper by Professor Forbes. He (Mr. Mordey) would first sum up the author's present grounds for preferring open circuit transformers. They were—(1) That iron is wasteful, hysteresis loss heavy and continuous; (2) that losses are easily ascertainable by calculation only, from C^2R in the conductor, by Ewing's or Hopkinson's curves for hysteresis (which he stated is constant for all loads), and by calculation of the eddies; (3) that these phenomena in iron and the action of transformers being understood fully only "phenomenal iron" can improve closed circuit transformers; (4) that tests of closed circuit transformers by various observers showing high efficiency are wrong; (5) that magnetising current was large even in the closed circuit type.

On the question of these losses, Mr. Mordey said that careful tests were needed to decide the points, not calculations. Many independent observations on closed circuit transformers by various methods—such as the calorimeter method, used by Professor Ayrton and others; the "split dynamometer" method, devised by Mr. Blakesley, &c.—had shown the efficiency to be very high. The method he had himself devised and alluded to in 1889—viz., finding the steady temperature to which the transformer is raised when working at a known output, and then determining the loss by supplying, with direct currents, sufficient power to maintain this temperature—led to similar results. Recent tests of a 6 kilowatt transformer of his own design by the latter method gave the loss on open circuit as 110 watts, and at full load 205 watts, of which 176 are accounted for by C^2R in the copper. This leaves only 29 watts for the iron losses at full load, whereas at no load they amounted to 110. On calculating the theoretical iron loss from Ewing's curves, it came out 180 watts at the magnetisation employed. These results show that as the loss in the copper increases the iron losses diminish, and that conclusions based on the assumption that the iron losses are constant and can be calculated from Ewing's curves are erroneous. On the basis of the above tests, the efficiencies at various loads of the particular transformer were calculated to be as follows, the first and last being determined by experiment, the intermediate filled in by calculation:—

Load.	Efficiency.
Full	96·7
¾	96·2 approx.
½	92·1 „
⅛	86·7 „

At no load the total loss was 1·8 per cent. of the full output, and the apparent loss (viz., C × V) 3·1 per cent., the lag between e.m.f. current (determined simply from the ratio of the true to the apparent waste) therefore being 53° and 54°. On the subject of "all day efficiency," which the author finds to be very low in closed circuit transformers, Mr. Mordey gave the following numbers as relating to the transformer above mentioned, which was one of the Brush Company's ordinary type:—

Full load for 4 hours	(20 hrs.)	All day efficiency.
¾	„	86
½	„	82·7
¼	„	68·6
⅛	„	52·6

He remarked that the small difference between the steady temperature of transformers working at no load and at full load was noticed by him in 1889. For instance, in one case this rise of temperature was 48° F. at no load, whilst at full load it was 43° F. only. From this observation no one could infer that either the transformer was very inefficient, or that the loss in the copper was very small, or that some other explanation was needed. Now he knew that neither of the first two suppositions was correct, hence the necessity for some other explanation. Just before the meeting Professor Ayrton had shown him some tests of one of his transformers, made by Blakesley's method. These tests conducted by Professor Ayrton confirmed his own. These tests, together with many others, made by disinterested observers, all point to the conclusion to which he had been led—viz., that the losses in the iron decrease with the load.

He submitted that these results, if correct, upset every one of the author's bases. But even if the author's contentions were true, the low "plant efficiency" obtained would seriously interfere to prevent the practical use of transformers constructed in accordance with his views. The author confessed to three-tenths of the plant being required to supply the magnetising current, but stated that closed circuit transformers require two-thirds as much, which is by no means the case. The use of condensers would reduce this great disadvantage of open circuit transformers, but it must be remembered that condensers would also reduce the small disadvantage of closed circuit transformers. If satisfactory condensers could be obtained (and he congratulated the author on the progress he seemed to have made in that direction), he thought the outlook for closed magnetic circuits was better than ever.

Mr. Crompton said that in the first place the number of hours required for transformers to attain a steady temperature was much greater than Mr. Mordey would have us believe, for he (Mr. Crompton) had kept them running for thirty hours, and still the temperature was not constant. Referring to "all-day efficiency," he said most people speak of the efficiency of transformers being 90 per cent. at half load, as if that was their normal working condition. This load was far above the average output even during lighting hours. Taking the case of a customer whose lighting bill, at 8d. per unit, amounts to £20 a year, he said such a house would require a 50 to 60-light transformer, and the average consumption throughout the year would be 70 watts. The transformer would thus be working on an average at $\frac{1}{16}$th its full load. On the question of "storage" he could not agree with Mr. Swinburne's opinions, for in stations subject to uncertain loads the employment of accumulators to the extent of 20 or 30 per cent. of the total output enabled the working expenses to be reduced immensely.

Mr. Addenbrooke remarked that Mr. Swinburne was under a wrong impression when he stated that probably no existing company intended changing their system of supply, for he (Mr. Addenbrooke) well remembered that when Mr. Ferranti took out his first patents for transformers, the subject of sub-stations and low-pressure distribution was thoroughly appreciated by the inventor. At that time, however, it was impossible to found sub-stations, but it had always been the intention of Mr. Ferranti, as well as of the House-to-House Company, to adopt this system whenever they could.

Mr. Evershed said the action was much easier to understand on the armature reaction theory than by the older ideas about self-induction. Referring to the compound machines mentioned, where the magnets are excited by a redressed alternating current, he inquired how the sparking could be got over? In conjunction with Mr. Vignoles, he had made many experiments on the loss by hysteresis in different samples of iron, and had never found a sample give more than 25 per cent. more loss than Ewing's specimen; only one sample gave this value, and it was an ordinary bar taken out of a smith's shop. In most cases the losses are about 5 per cent. more than that found by Ewing. On the subject of efficiency of transformers he said Mr. Swinburne had not taken a good design of closed circuit converter with which to compare his "Hedgehog."

Mr. Swinburne here remarked that in his British Association paper he had given the best proportions of copper and iron for the closed circuit form, but in this paper he had taken an average of the various forms in the market.

Mr. Evershed said that to be anything like a good design there should be much more copper in it. The subject of open *versus* closed circuit transformers had occupied his attention for some time, and he found that, if the iron circuit of one of the latter form was cut, its efficiency is increased. Such being invariably the case, he said, Why not "go the whole hog or none," and do away altogether with the iron core. Recently he had worked out the dimensions of a 10 horse-power transformer made on this plan, and found that at a frequency of 210 the weight was 200lb., and the saving resulting from the absence of a core amounts to 20 per cent. per annum on the cost of the transformer.

THE ELECTRIC TRANSMISSION OF POWER.*

The formulæ of Table II. of the last lecture are developments of Sir William Thomson's well-known law for the most economical conductor for the electrical transmission of energy; the law itself is based upon erroneous assumptions, the chief of which is that power has the same value at the receiving end as at the generating end, and to be of practical applicability requires to be modified according to the table. The higher the voltage employed the less the cost of copper in the conductors, but the greater the cost for the insulation of the conductors and for the generating and receiving plant, and from this it follows that there is a certain voltage at which it will be most economical to work. The maximum voltage at which continuous current machines will work satisfactorily depends upon the commutator and upon the general insulation of the machine, and at present the limit is from 2,000 to 3,000 volts.

Table IV. of the last lecture gives the total capital outlay for the electrical parts of several power transmissions actually carried out by the Swiss Oërlikon Works, who have also erected the Schaffhausen installation, which we will now briefly describe.

As an example of a large and successful transmission plant, the installation at Schaffhausen, on the Rhine, may well be taken. The power is transmitted from a

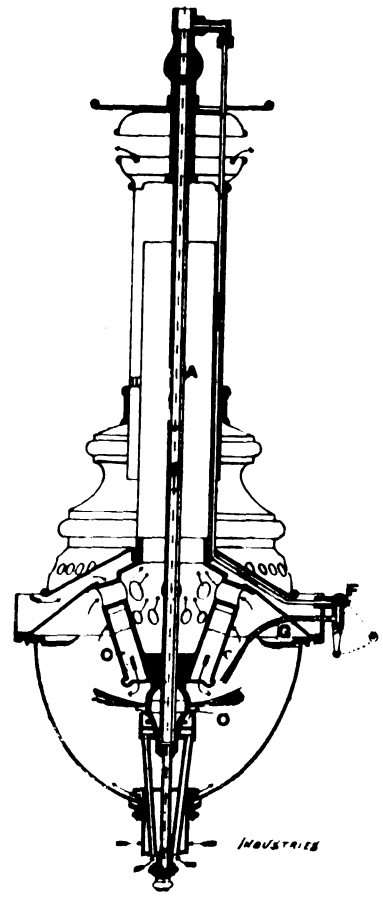
* Abstract of Cantor Lecture delivered at the Society of Arts by Mr. Gisbert Kapp, M.Inst.C.E., on the 2nd inst.

Digitized by Google

turbine station across the Rhine to the Schaffhausen spinning mills, a distance of about 750 yards. At the generating station there are four turbines, each of 350 horse-power, of which only two are at present in use, and the energy delivered at the turbine pulleys is sold to the mill owners at the rate of £2 16s. per horse-power per annum. From the turbine pulleys two six-pole dynamos are driven by cotton ropes, each dynamo having an output of 330 amperes at 624 volts when running at 300 revolutions per minute. These machines are over-compounded, so as to give a constant potential of 600 volts at the motor end of the line, and in ordinary working are coupled in parallel. At the receiving station there is a twin motor of 380 horse-power, and two other motors, each of 60 horse-power. The twin motor is six-pole, and the smaller motors two-pole, and the power is transmittd from them to the mill shafting by cotton ropes. Full particulars of the machines are given in the accompanying table. There are four main conductors, all overhead, each having a sectional area of ·437 square inch, and being supported by iron towers 46ft. high; the span across the river is 330ft., and each of the remaining spans are 430ft. The guaranteed commercial efficiency reckoned from the turbine pulleys is 78 per cent., the variation of speed of the motors between full and no load not more than 3 per cent., the life of a set of brushes not less than 2,000 hours, and of a commutator not less than 20,000 hours. The total cost of the electrical part of the plant, including iron towers and erection, was £6,800.

THE SCHAFFHAUSEN TRANSMISSION PLANT.

	Generators.	Twin Motor.	Small Motors.
Number of machines	2	1	2
Normal horse-power	300	380	60
Number of poles in magnet fields	6	6	2
Revolutions per minute	300	300	350
Terminal voltage	624	600	600
Normal current, amperes	330	500	81
Diameter of armature, inches	47½	42½	23⅝
Length of armature core, inches	20	20⅜	22½
Radial depth of armature core	8	7	4⅜
Section of armature conductor, square inches	·103	·078	·0287
Number of armature conductors	316	316	540
Number of commutator segments	158	158	90
Loss in armature resistance per cent.	1·46	1·52	2·7
Induction in armature, C.G.S. measure	7,500	7,600	15,800
Shunt resistance, ohms	140	143	295
Loss in shunt excitation per cent.	1·35	1·68	—
Main turns per magnet	6	4	—
Loss in main excitation per cent.	·3	·2	—
Type of armature	Drum	Drum	Cylinder



At Niagara there is about 3½ million horse-power running to waste, and of this the Cataract Company intend to utilise 125,000 horse-power by transmitting it to towns and places where it is required. The maximum distance for transmission will be about 20 miles. The electrical transmission of so great a power is at present rather beyond engineers, but in a few years the difficulties surrounding the problem will doubtless be overcome. In the recent competition instituted by the Cataract Company, out of fifteen different schemes seven proposed electrical transmission, six pneumatic, and two hydraulic; of the electrical schemes, two advocated alternating current transmission at 5,000 and 10,000 volts, and the remaining five continuous current transmission at potentials varying from 1,600 to 4,500 volts. The company are at present making a tunnel 30ft. high, 20ft. wide, and 6,700ft. long, which will form the tail race from the water motors to be erected.

The use of alternate current generators and motors for large transmissions has much in its favour; there are no commutators, and by having transformers at both ends of the line the working potential may be 10,000 or 25,000 volts, or even higher still, while the potential at the machines is only a few hundred volts. An ordinary alternate current dynamo can easily be run as a motor, but, as such, it is not self-starting, and if overloaded to the extent of 50 or 100 per cent., may get out of step with the supply current and come to a standstill. There is another method of alternate current transmission, known as the "three-phase current" system, which has neither of the above objections; it is a development of the Ferraris two-wire and of the Tesla three-wire systems, but with it the transmission and plant efficiencies are much greater than with the Tesla system. An objection to the Ferraris system is that the speed of the motor is not self-regulating, but may vary from zero to the synchronising speed according to the load. The action of the Ferraris, Tesla, and "three-phase current" systems was very clearly explained with the help of models and diagrams.

At the conclusion of the lecture several electrical machine tools were shown in action. These included a drilling machine, which held itself to the iron plate to be drilled by means of powerful electromagnets, mining tools, and a tube cutter. A transformer was also shown suitable for use with oil insulation; such a transformer has lately been used at Messrs. Johnson & Phillip's works, to transform from 2,400 to 17,000 volts.

STEUTH'S REGENERATIVE GAS LAMP.

WE illustrate below a new form of regenerative gas lamp which is being introduced into this country from Germany by Mr. F. H. Cheesewright, 60, Haymarket, S.W. As will be seen from our illustration, the gas is supplied to the burner O, which is an ordinary annular argand, through the tube A. Above the burner is situated a conical copper regenerator C, which is of special construction. The invention relates chiefly to the means adopted for supplying a small quantity of air to the burner from below by an arrangement of tubes communicating with the external air at the

bottom of the lamp, as shown in our illustration. A further novelty for this kind of burner is an arrangement for enabling the ignition of the lamp to be effected from the outside of the glass shade, which consists of a supply pipe passing from the top of the burner down one side of the regenerative portion of the lamp to the small stop cock F, which, when open, allows a small jet of gas to burn at the end of the tube G sufficient to ignite the burner when desired. We await the trials which it is proposed to make with this lamp against the other forms of regenerative burners already in the market.

NOTES ON ALLOYS.

IX.

SINCE our last article on this subject Messrs. Heycock & Neville have communicated to the Chemical Society a second paper on the molecular condition of metals when alloyed with each other. It will be recollected that they have already shown that one atomic proportion of a metal when dissolved in tin produces a lowering in the solidifying point of that metal equal to that which, on the theory of osmotic pressure, should be produced by one molecular proportion, and they therefore concluded that metals dissolved in tin have monatomic molecules. They have carried out similar experiments, using bismuth, cadmium, and lead as solvents, and find that most metals in these solvents also have monatomic molecules. The chief exceptions which the authors have met with are thus summarised:—Arsenic, both in bismuth and cadmium, gives a fall of one-third that of most other metals; antimony, when added to bismuth, gives a rise in the melting point; in cadmium, zinc, palladium, and mercury give smaller falls than the other metals, whilst silver gives a very pronounced rise. Of the fourteen metals dissolved in lead, five would appear to have monatomic molecules, while mercury, bismuth, and cadmium are diatomic, and tin tetratomic. This investigation seems to show that the number of atoms in a molecule of a metal depends not only on the temperature, but on the kind of solvent employed.

Greene and Wahl have also studied the alloys of sodium and lead. They prepared them by direct combination of the two metals, by reducing litharge with charcoal in the presence of caustic soda, and by heating litharge with sodium tartrate after the method proposed by Vanquelin and Serullas. The alloys are all brittle and crystalline, and contain from 3 to 31 per cent. of sodium. The alloy richest in sodium is green, and instantly blackens on exposure to the air. The densities are higher than that of simple mixtures of the two metals, and they give the formulæ Na_2Pb_2, Na_2Pb, and Na_4Pb for the compounds which they have prepared by these methods.

As interesting to electricians we give the values for the specific resistance and temperature variations for the alloys which are commonly employed for electrical work. The following table summarises the results obtained by Mr. Mordey, of the Brush Company:—

	Specific Resistance.	Temperature Variation per 0° C.
Copper	1·00	0·396
Soft iron	5·27	0·691
Brass	6·05	0·164
German silver	8·88	0·080
Piano wire	16·00	0·517
Platinoid	20·00	0·044
Arsenical copper	28·50	0·061
Hadfield's manganese steel	37·10	0·229

W. Hallock has recently shown that an alloy of two or more metals can be readily prepared by first mixing the filings of the constituent metals in the given proportions, and then allowing the mixture to remain for some time at a temperature above the melting point of the alloy to be formed. He was led to carry out these experiments, and thus establish the law enunciated above, from reading W. Spring's well-known experiments upon the formation of Wood's alloy by pressure. It will be recollected that in this research the filings were first mixed, then compressed under a pressure of 6,000 atmospheres, and the block of metal so formed again filed up and compressed, when a homogeneous alloy was produced. Hallock argued that if in any part of the mixed filings the four constituent metals were in contact a molecule of the alloy would be produced, and if the temperature be above its melting point it would flow away, and in so doing probably bring another four particles of the dissimilar metals in juxtaposition, and so tend to continually produce the alloy from the admixture without pressure or melting any of the constituents. The law was established by producing Wood's metal in a test tube from the filings of the constituent metals at the temperature of the water bath—*i.e.*, at 130° below the melting point of the tin, which is the most fusible of the constituent metals. The tin lead alloy was similarly prepared by allowing the mixed filings to remain at the temperature 190°–200° for some days; and the formation of the well-known sodium potassium liquid alloy by the mere contact of the two metals at ordinary temperature is cited by Mr. Hallock as confirmatory evidence of the generality of his statement.

Two recent processes for the manufacture of ferro-aluminium have been patented by Faure, and by Pratt and Pearson. The former consists in passing the vapour of ferric chloride over bauxite and charcoal heated to redness. The vapours so formed are then led over scrap iron, also at a red heat. The iron is attacked by the aluminium chloride vapours, forming ferro-aluminium and ferrous chloride. The latter is condensed and heated again in a current of air, when it is converted into oxide and ferric chloride, which volatilises, and is ready for a fresh operation. Pratt and Pearson's process is one for making an aluminium cast iron in an ordinary blast furnace. This is effected by calcining the iron-stone with clay, coke, and fluor spar, instead of lime, but the authors do not state what is the maximum amount of aluminium that can be introduced into the iron in this way. A German patent (No. 54132), by Petit Devancelle, covers the preparation of aluminium-bronze from the alloys of copper with tin, zinc, or lead. When any of these alloys are heated with aluminium sulphide, the sulphur unites with the second metal, forming its sulphide, and a copper aluminium alloy is produced containing from 5 to 10 per cent. of aluminium.

According to L. Dienelt (D.R.P., 54,216), German silver gives very unsatisfactory castings if the nickel is not thoroughly incorporated with the molten copper. He suggests that the nickel should be first fused, and when it is completely fluid, the copper added thereto. Zinc, tin, or lead can then be added to the fused mixture. The most satisfactory mixture is copper 4, zinc 2·5, lead 0·75, nickel 0·5, and tin 0·125 parts, making 7·875 parts of German silver. He claims that this alloy is as white as German silver, can be worked as easily as brass, and is cheaper than ordinary German silver. Tin is the best metal to use as a solder for this alloy, as, being white, the joint is not apparent. The molten alloy is very fluid, and the patentee states that it gives very sharp and well-defined castings.

An alloy containing 9 parts of lead, 2 of antimony, and 1 of bismuth has the property, like other antimony alloys, of expanding on cooling. It has been suggested that such an alloy could be utilised for repairing cracks in cast iron. Of course, it is readily fused, and therefore could not be employed for any work which might subsequently be subjected to a high temperature.

BEESWAX AND ITS PURIFICATION.

MM. A. and P. Buisine have lately completed an examination of the various processes employed for bleaching beeswax, which throws some light on the variation of the quality of commercial white wax. They find that wax is generally bleached by simple exposure to the air and light, the colouring matter being slowly oxidised. Pure oxygen and ozone can also be employed for this purpose, but light is absolutely necessary to bring about the change. They also state that in the absence of free oxygen—*e.g.*, in carbonic acid, nitrogen, or a vacuum—light slowly decolorises yellow wax. Yellow wax differs from wax bleached by exposure to the air in containing less free acid, a smaller saponification value, and a higher iodine absorption. In the bleaching process, then, not only is the colouring matter completely destroyed, but the non-saturated fatty acids and hydrocarbons present in the wax absorb oxygen and form saturated compounds having a smaller iodine value. In practice, the bleacher generally adds from 3 to 5 per cent. of fat to the wax before exposure to light to increase the rapidity of the bleaching action and to diminish the brittleness of the finished product. A bleached wax to which this small quantity of lard has been added can be recognised by its higher saponification equivalent and a slight increase in the amount of free fatty acids. Oil of turpentine added in small quantities to the wax acts in the same way as lard. When animal charcoal is employed for bleaching crude beeswax, its composition is very slightly altered; it is, therefore, easy to identify a wax which has been bleached by this treatment. Certain oxidising agents—such as potassium permanganate and bichromate in acid solution—are also employed with very good results for bleaching beeswax. Hydrogen peroxide has also been used with success. Reducing agents, sulphites, hydrosulphites, and sulphurous acid have no action on the colouring matter, and chlorine and bleaching powder cannot be employed, as, in addition to destroying the colour, the chlorine is retained by the wax and so modifies its properties that it is rendered useless for many of the purposes for which it is manufactured. The authors, in their paper in the *Bulletin de la Société Chimique de Paris* (1890, 470), give tables of their analyses of wax bleached by all of these methods, which will be found useful to those who have difficulties in getting wax of definite composition.

Notes.

JAPANESE NAVAL POLICY.

It is stated that the Japanese Government intends to lay before Parliament a very extensive naval policy, the details of which will excite interest in shipbuilding circles in this country. The Japanese have never concealed their ambition to make their country the Britain of the East, both as regards its navy and its mercantile marine, and already both of these have attained very considerable importance. The Government, however, thinks that the former is too small, not only on account of the work it has to do, but also as compared with the navies of foreign Powers, and it is proposed to obtain or build twenty-five ships, exclusive of those in course of construction in Japanese and foreign yards, so as to make the total available ships in the navy seventy-five. The ordinary appropriation for the navy is about one million sterling, an amount which the Admiralty authorities say is barely sufficient to allow for ordinary tear and wear. They have, therefore, drawn out a special programme, extending over seven years, and which they intend to lay before Parliament, and ask for a special grant, sufficient to enable them to construct or buy during the current year two belted cruisers and three torpedo boats, and the demand will be repeated from year to year till the programme has been completed. Some of the vessels will be constructed in Japan, but the most of the work will be done in foreign yards.

PREPARATION OF OXYGEN FROM THE AIR.

E. Peitz has patented in Germany a new process for obtaining oxygen from the atmosphere, which seems to possess certain advantages over the older processes, and which, like Mr. Kassner's method (see *Industries*, Vol. IX., page 508), is based on the employment of lead oxide for this purpose. Lead oxide and chalk are heated together in a current of air, when carbonic acid is given off and the following reaction takes place:—

$$2CaO + PbO + O = Ca_2PbO_4.$$

When cooled to a dull red heat carbonic acid is led over the mass at such a rate as to reform calcium carbonate and evolve pure oxygen gas, thus:—

$$Ca_2PbO_4 + 2CO_2 = 2CaCO_3 + PbO + O.$$

The mixture in the retort can be reconverted into calcium plumbate by reheating in a current of air to a bright redness.

BELGIAN IMPORTS AND EXPORTS IN 1890.

The following list of imports and exports in Belgium during last year shows that, while there was a marked increase in imports, there was also a slight increase in the exports, as compared with the previous year:—

	Imports in Tons.		Exports in Tons.	
	1890.	1889.	1890.	1889.
Coal	1,727,011	1,004,624	4,537,708	4,272,700
Coke	65,119	18,545	1,062,930	1,219,959
Briquettes	—	—	310,842	317,164
Iron ore	1,644,421	1,805,210	171,392	155,108
Rough cast steel	9,883	6,532	453	3,168
Steel rails	756	1,107	73,867	69,672
Rolled steel	3,779	3,430	26,121	36,874
Worked steel	1,053	1,308	8,983	8,503
Raw pig iron	250,952	238,361	11,309	14,773
Old iron	18,634	24,996	11,757	7,801
Iron wire	3,811	3,262	2,340	4,843
Iron rails	156	609	12,857	14,642
Sheet iron	1,859	2,026	45,679	55,842
Iron (various)	10,089	11,662	217,960	257,884
Nails	665	572	10,103	13,801
Worked iron	3,673	3,724	35,244	37,324
Worked pig iron	2,381	2,215	30,896	28,127
Total tons	3 744,242	3,128,183	6,570,441	6,518,185

COAL IN BURMAH.

The coalfields in the Upper Chindwin District and the country between the Myitthia and Yu rivers have been examined. The total area is 175 square miles. According to the *Indian Engineer*, the seams are described as numerous, though the majority of them are of small thickness, but few exceeding 3ft., and one only measuring 10ft. The coal, however, is of first-rate quality, hard and bright, and makes excellent fuel. A syndicate has been granted a lease of six square miles, and will begin mining at once. The Thayetmyo field has proved a failure, owing to the insufficient quantity of the coal and the disturbed strata; but the Theingudaw fields on the right bank of the Irrawaddy promise to repay the lessees. In the Northern Shan States there would appear to be abundance of coal. It crops out in the Lashio and Hamma districts, being found in the beds of streams. Dr. Noetling made a surface examination of the country, and at Lashio he traced one seam of 30ft. thickness for two miles. So far as it has been proved, this coal is rather poor in quality, being very light and liable to crack when dry, but it is said that this may possibly be due to long exposure to air and water in the river bed. Until a series of borings has been made, its true quality can scarcely be declared. Lashio is too far distant from Mandalay for the coal to be worked in paying quantities now, but when the railway is extended through the Northern Shan States, as it is certain to be in a few years' time, this drawback will disappear.

THE WORLD'S POPULATION IN 1890.

The following table from the Proceedings of the Royal Geographical Society for January, 1891, is of interest:—

	Population.	Average to a Square Mile.	Increase per Decade per Cent.
Europe	380,200,000	101	8·7
Asia	850,000,000	57	6
Africa	127,000,000	11	10
Australasia	4,730,000	1·4	30
North America	89,250,000	14	20
South America	36,420,000	5	15
Totals	1,487,600,000	31	8

This table shows that if the population were equally spread over the differents parts of the globe, there is not much fear of over-population for many years to come.

FRENCH IRON AND STEEL STATISTICS.

The following statistics show the quantity of iron and steel imported and exported in 1890, as compared with 1889:—

Imports.	1890.	1889.
Cast Iron.	Kilogrammes.	Kilogrammes.
For temporary admission	115,457,700	107,165,700
Paying duty	20,648,000	13,025,000
Total	136,105,700	120,190,700
Wrought Iron.		
For temporary admission	17,624,500	13,109,100
Paying duty—		
Forge scales	100,552	153,699
Charcoal bars	7,303,978	7,840,686
Coke bars	3,704,020	3,762,701
Rails	211,069	62,090
Angle and T irons	207,157	61,907
Rods	59,611	142,083
Hoop iron	121,577	79,668
Sheet iron	851,590	1,168,262
Galvanised iron, &c.	2,109,711	1,706,584
Iron wire	259,864	313,232
Total	32,553,629	28,400,012
Scrap iron	8,218,683	15,063,762
Slag	29,203,558	22,532,991
Steel.		
For temporary admission	2,745,300	3,949,600
Paying duty—		
Rails	812,427	90,111
Axles and tyres	990,371	922,498
Bars and sheets	2,926,927	2,743,097
Ordinary plates	214,620	138,842
Hoop steel	166,678	155,243
Steel wire	553,815	581,935
Total	8,410,138	8,580,826
Exports.		
Cast iron	171,243,000	120,007,000
Wrought iron	66,689,797	67,614,113
Steel	43,815,320	36,819,126
Scrap iron (wrought and cast)	26,852,468	17,616,802
,, steel	439,055	326,097

THE COTTON INDUSTRY.

The weaving trade does not improve; in fact, the depression previously referred to last week continues, with the tendency here and there for more looms to stand idle. The estimate of weaving machinery quite at a standstill is now put at 20,000 looms, chiefly in East and North-East Lancashire. Some discussion has been reported of an effort to get general short time in manufacturing, but no progress has been made in this direction, and it is felt that, owing to the position of producers being so diversified, success will not attend those who are asking for concerted action. Rumour has it that a great deal of money has been lost in weaving recently. Last week one old firm in Blackburn came to grief. The only hope for those who buy yarns is that coptwist and weft values are receding. It is certainly a very long time since 32's coptwist touched 7½d., its present value. Moreover, the prolonged lessening of production is sure to have its effect upon the great Eastern outlets. The nearer and minor outlets are helping the market a little, but the want of demand from Bombay and Calcutta is a serious blow to the industry. Cotton spinning, as distinct from weaving, is also in a bad condition. Not only have Oldham spinners large supplies of dear cotton, but they are finding great difficulty in obtaining delivery of yarn orders taken at much higher rates than those now current. Stocks of bundles and cops are getting rather burdensome in first hands. There is some discussion as to whether the recent advance in wages should not be taken back by the employers.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

16th February, 1891.

2746. Triscott, C. M. P. H. ... Appliance for loading repeating firearms.
2751. Fell, J. ..... Steam boilers.
2753. Tomlinson & Porter ... "Gassing" and finishing silk and other yarns.
2758. Wilson G. A. ..... Apparatus for folding and collecting sheets of paper.
2759. Leather, J. ..... Apparatus for ventilating mines.
2760. Nall, J. ..... Dovetailing machines.
2761. Healey, B. D. ..... Combination chambers of furnaces.
2765. Nichols & March ..... Gas locomotives.
2769. Sturrock & Macdougald Stuffing-boxes for fluid pressure motors, &c.
2771. James, T. ..... Axle-boxes for railway vehicles.
2778. Dennis & Avis ..... Railway signalling apparatus.
2779. Skilton, J. A. ..... Heating and ventilating apparatus.
2780. Coddington, V. W. ..... Separable pulleys.
2781. Coddington, V. W. ..... Pulleys.
2782. Newman, T. ..... Pipe wrenches.
2784. Wallwork, J. ..... Apparatus for placing fog signals.
2785. Tropenas & Wells ..... Apparatus for the determination of carbon in steel.
2794. Spence, J. ..... Apparatus for adjusting saws of stone-cutting machines.
2795. Barber, S. ..... Apparatus for cleaning coal, coke, metal ores, pulps, &c.
2796. Guy, C. W. ..... Crushing mills.
2797. Duffield, C. ..... Tunnelling machine.
2806. Lea & Trueman ..... Apparatus for returning water of condensation to boilers.
2811. Heidelmann, W. ..... French circular hosiery machines.
2815. Rouzay, M. ..... Gas or petroleum engines.

17th February, 1891.

2821. Matthews, J. ..... Movable spanner.
2827. Rigby, R. ..... Mandrels for drawing thin metallic tubes.
2835. Jenkin, C. F. ..... Rope gearing for driving cranes
2843. Blakeney, W. H. ..... Apparatus for delivering mails to trains in motion.
2845. Walton, W. ..... Mechanism for feeding bisectional wire into card-setting machines.
2850. Mauser, P. ..... Safety mechanism of breech-loading small arms.
2854. Baxendale, W. ..... Steam boilers.
2858. De Pass, E. ..... Ring-spinning frames (*Imbs*).
2860. Dalglish & Boyd-Wilson ..... Brake-controlling mechanism.
2869. Floyd, J. N. ..... Steam pumping engines.
2870. Newton, H. E. ..... Web printing machines (*H. Hoe & Co.*).
2871. Newton, H. E. ..... Cylinder boring machines (*Worthington*).
2881. Little, H. W. ..... Steam engines (*Little*).
2882. Arnold, L. G. ..... Railway car brakes and buffers.
2883. D'Auria & Robert ..... Direct-acting steam pumping engines.
2889. Thompson, W. P. ..... Apparatus for the manufacture of gas from petroleum (*Sanford*).
2891. Eves, J. V. ..... Flax machinery.
2896. Pigeot, E. ..... Horse nail machinery.
2898. Williams, H. A. ..... Apparatus for rolling wire.
2905. Marston, C. E. ..... Steam boilers.

18th February, 1891.

2929. Williams, H. ..... Mechanism for governing gas and oil engines.
2932. Lister, E. J. ..... Apparatus for polishing wire.
2939. Fielding, J. ..... Gas motor valve apparatus.
2949. Munns, W. H. ..... Stencil printing apparatus (*Harrison & Heiskell*).
2951. Munns, W. H. ..... Pipe wrench (*Sproull & Sproull*).
2953. Munns, W. H. ..... Machines for cutting irregular shapes (*Niermann*).
2954. Munns, W. H. ..... Mechanism for converting rotary into reciprocating and other motion (*Coburn & Coburn*).
2961. Hartig, H. ..... Expansion gear for steam engines.
2967. Barstow & Shaw ..... Boiler furnaces.
2974. Murrie, J. ..... Boiler feed and alarm mechanism.
2975. Barraclough, T. C. ..... Machinery for manufacturing metal barrels.
2976. Hughes, F. ..... Gas engines (*Cordenous*).
2988. Baldwin, F. R. ..... Vacuum boiler tube cleaners.

19th February, 1891.

2997. Thompson, W. P. ..... Rotary swaging machines (*Collins*).
3009. Field, R. ..... "Streamers" employed in looms.
3014. Clapham & Greenwood Steam boilers.
3026. Lindley, F. A. ..... Paper-making machines.
3027. Broadhurst, H. B. ..... Jacquard apparatus.
3033. Spencer & Ralston ..... Stop cocks or valves.
3035. Thwaite, B. H. ..... Apparatus for manufacturing Portland cement.
3036. Stratton, J. M. ..... Steam boilers.
3043. Bohm, W. D. ..... Pumps.
3062. Darby, J. H. ..... Steam engines.
3068. Gallagher, H. ..... Machinery driving gear.

20th February, 1891.

3074. Fielding, J. ..... Gas regulator for gas engines.
3075. Fielding, J. ..... Governing apparatus for gas engines.
3087. McGee & McGee ..... Thread winding machinery.
3093. Trier, F. ..... Lubricators.
3097. Breadner, E. ..... Picking bands for looms.
3098. Breadner, E. ..... Machine for dyeing, drying, chroming, washing, mangling, and plaiting textile fabrics.
3100. Dearden, E. ..... Machinery for manufacturing wheels for railway vehicles.
3111. Bailey, J. ..... Apparatus for making rugs.
3121. Barker, R. W. ..... Car couplers (*Frost*).
3122. Bohl, J. G. ..... Spinning tubes.
3125. Dvorkovitz, P. ..... Apparatus for making gas and distilling crude hydrocarbon oils.
3128. Pickard, A. ..... Square hole drilling machines.
3129. Richardson & Coates ... Crushing machines.
3138. Paulick, G. ..... Machine for tying up the cards in jacquard machines.
3151. Fry, H. W. ..... Apparatus for crushing grain.
3160. Hammesfahr, E. ..... Rotary engine.

21st February, 1891.

3165. Ferguson & Fleming ... Compound steam engines.
3173. Brown, Coop, & Hurst Band-cutting machines for cloth, &c.
3188. Eckert & Hentschel ... Machines for making buttons.
3201. Dunbar, J. ..... Dredgers.
3215. Grenfell & Baron ..... Lathes for the manufacture of screws.

ELECTRICITY.

17th February, 1891.

2862. Dewey, M. W. ..... Electric fire engines.
2902. Grimston & Wilson ..... Electric locomotives.

18th February, 1891.

2985. Edwards, E. ..... Apparatus for stirring malt and grain (*Sandt & Sturm*).

19th February, 1891.

2999. Bigland & Burns ..... Arc lamps.
3003. Mayer, E. W. ..... Element for electric battery.
3030. Ward, M. R. ..... Propelling vehicles by electric motors.
3049. Mills, C. K. ..... Circuit controller and alarm (*Woolcott & Wilmot*).

20th February, 1891.

3127. Cruyt, W. ..... Apparatus for indicating loss or diminution of current in circuits.

21st February, 1891.

3191. Dolivo-Dobrowolsky & The Company Allgemeine Elektricitäts-Gesellschaft ..... Transmission of alternating differential phase currents.
3198. Poudroux, F. ..... Galvanic batteries.
3199. Harold & Jenkins ..... Switches.

CHEMISTRY.

16th February, 1891.

2747. Hutchinson & Harboard Utilisation of slags in conjunction with finely divided oxides of iron.
2798. Altman, H. J. ..... Solutions and salts for electro-deposition.
2805. Lake, H. H. ..... Colouring matters (*A. Leonhardt & Co.*).
2812. Zeitler, J. N. ..... Converting carbonate of lead, obtained from sulphate of lead with carbonate of sodium, into basic salt.
2817. Imray, O. ..... Colouring matters (*The Society of Chemical Industry*).

19th February, 1891.

3034. Fanta, F. ..... Producing oxygen gas. (22nd October, 1890.)
3057. Faure, C. A. ..... Production of aluminium alloys. (2nd December, 1890)

21st February, 1891.

3210. Gemmell, T. ..... Treatment of auriferous and argentiferous ores.

MISCELLANEOUS.

16th February, 1891.

2776. Horton, J. ..... Sensitive ball tap.
2789. Price, W. L. ..... Armour plates.

17th February, 1891.

2853. Middleton, J. J. ..... Covering for steam boilers, &c.
2873. Burdon, L. L. ..... Manufacture of seamless compound ingots and wire.
2904. Mannesmann, R. ..... Manufacture of metal tubes.

18th February, 1891.

2928. Dearden, E. ..... Manufacture of wheels for railway vehicles.
2991. Mannesmann, R. ..... Rails for railways.

20th February, 1891.

3072. Cadman, S. ..... Oil cans.
3101. Limb, T. ..... Miners' safety lamp.
3116. Ehrhardt, H. ..... Punching and shaping iron and steel blocks.

21st February, 1891.

3189. William Gilpin, Senior, & Co., Ld. ..... Augers, bits, drills, and other boring tools.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

18463. Vallet. 18643. Higginbottom.

1890.

813. Imray (*Moerchen*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Safety Valves.—*G. Weir & J. Weir, Cathcart, Lanark, N.B.*—The invention has for its object to ensure the equal pressure upon all parts of the surface of contact of the valve. A cylindrical casing fixed concentrically over the opening in the boiler has fixed in its lower end a valve seating of the ordinary construction, on a line with the upper edge of which suitable holes are formed in the casing for the escape of steam. Screwed into the upper end of the casing is a tubular piece, the lower end of which projects into the interior of the casing, and has a convex spherical surface. Screwed into this tubular piece is a suitable cover, through which is passed a key, also passing through a slot in the upper end of the valve spindle, so limiting the latter's movement. This valve spindle, which passes downwards through the tubular piece, has keyed loosely to its lower end the valve proper. Just above this valve a convex spherical flange is formed on the valve spindle, upon which, as well as upon the convex surface of the tubular piece, discs embracing the valve spindle, and formed with concave surfaces, are pressed by means of a suitable helical spring surrounding the valve spindle. From the above it will be seen that a universal joint is formed between the valve spindle and the actuating spring, and between the stationary part against the surface of which the latter bears. Claims: A spring loaded or safety valve having universal joints as described.—No. 4061. March 15th, 1890. 6*d*.

Steam Boiler Furnaces.—*W. P. Thompson, London. (A. Mason, Brooklyn, U.S.A.).*—The invention relates to a method of and apparatus for burning coal and hydrocarbon fuel in combination. The coal, in a finely pulverised state, and air are injected together into the furnace by means of a fan A shown in the accompanying illustration, through a nozzle B, the coal being fed into a hopper C, and thence into the tube D leading from the fan

to the nozzle. The inside of the combustion chamber is formed by means of deflectors E F G of a circular form, so that the coal injected into the furnace is held in suspension until complete combustion has taken place. The oil is injected into the furnace by means of a nozzle placed in the opposite side of the furnace to B and slightly higher than B. This nozzle consists of a steam nozzle H placed inside a second nozzle I, through which air is induced into the furnace, carrying with it the hydrocarbon fuel supplied from a tube J. In a modification the inventor uses one or more suitable burners located in the furnace chamber somewhat higher than the ashpit, with ample surrounding space for the ashes to descend into the pit without clogging these burners, and at the same time maintains a fire of coal around and above the oil or vapour burner or burners with pulverised coal atoms in suspension and general distribution throughout the chamber, together with the requisite amount of air for the support of combustion as above described. Three claims are made.—No. 16760. October 21st, 1890. 8*d*.

Car Couplings.—*A. H. S. Davis, Washington, & A. C. Brown, Minneapolis, U.S.A.*—Referring to the annexed illustrations, Figs. 1 and 2 are side elevations of adjacent drawheads, Fig. 3 an end elevation, Fig. 4 an inverted plan, and Figs. 5, 6, and 7 details of an automatic attachment to cars, already fitted with links and pin couplings, constructed according to this invention. A is the ordinary drawhead bar, and B B^1 clamping plates clamped by bolts on the upper and lower sides of A (Figs. 1 and 2). Formed on B^1 is a pendant C (Fig. 6) provided with notches C^1 for supporting the link lifter D (Fig. 7), by means of lips D^1. The other end of D is in the form of a cross-bar, and is fitted to slide horizontally in a bracket E. This link lifter D is so formed that when raised and drawn forward the lips D^1 will engage in

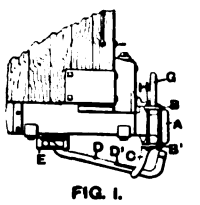

FIG. 1.

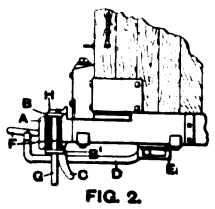

FIG. 2.

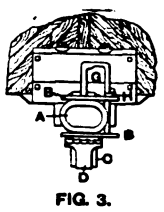

FIG. 3.

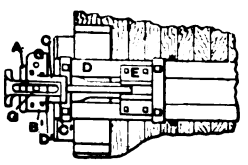

FIG. 4.

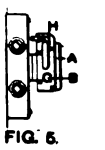

FIG. 5.

FIG. 6.

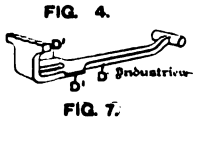

FIG. 7.

one of the slots C^1, so supporting it in a position that it holds the link F ready for engagement. G is the coupling pin, formed of a U shape as shown (Fig. 3), in one leg of which is formed a suitable notch, into which a catch H on the plate B engages when the former is in a raised position. When the cars are brought together the link lifter D strikes the opposite car, and is so forced backwards, by which action the lips D^1 are disengaged from the notches C^1, and D, together with the coupling link, is allowed to fall. During this operation a projecting part of the catch H strikes the car, so disengaging the former from the notch in G, and allowing the latter to fall and complete the coupling. Seven claims are made.—No. 15484. September 30th, 1890. 8*d*.

Metal Saws.—*G. Ryder, Bolton.*—In constructing saws for cold sawing metals the inventor forms the saw with a spiral periphery in place of a circular form, and provided with teeth round the whole of its periphery. Where a self-acting feeding motion is applied to the table of the machine on which the metal to be cut is secured, the inventor feeds the table toward the saw intermittently by positive gearing from the saw spindle, so that the material is advanced just after the largest diameter of the saw has passed through the metal. The inventor also proposes the formation of milling tools with spiral surfaces. Claims: A revolving cutter formed with its cutting edge arranged spirally, and either with or without tapered edges as described.—No. 5042. April 1st, 1890. 6*d*.

Yarn Beams for Looms.—*J. & R. Lindsay, Dundee, N.B.*—The invention has for its object to improve and simplify the construction of yarn beams for looms, and it consists principally in making the end flanges or discs of such beams of comparatively thin steel or wrought iron shaped to give the requisite strength or stiffness and provided with suitable bosses by means of which they are fixed on the barrels of the beams. The inventors prefer to combine this improved construction of end flanges with the arrangement described in a prior patent, No. 1916 of 1890, in which the drag appliances are applied to separate pulleys geared to the beam by toothed wheels. Claims: Making the end flanges or discs of yarn beams of looms of comparatively thin plates of steel or wrought iron, with the outer edges flanged outwards, the said end flanges being entire or in halves.—No. 12175. December 30th, 1890. 6*d*.

Reversing Gear for Electric Cars.—*G. R. Baldwin, Montreal, Canada.*—Referring to the annexed illustrations, Fig. 1 is a section of a reversing apparatus embraced by this invention, Fig. 2 being a plan showing the apparatus applied to an electric car, and Fig. 3 a detail thereof. As shown in Fig. 3, the two axles of the car are connected together by means of suitable gearing, and the shaft A is driven by means of the gear wheel B from a pinion on the armature shaft of an electric motor C. The gearing B is mounted loosely on A, and has fixed to its elongated hub a pinion D (Fig. 1). Mounted to revolve loosely on the hub of B is a disc E carrying studs F on which revolve the

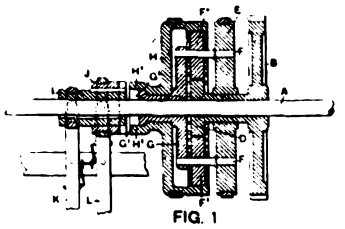

FIG. 1.

FIG. 3.

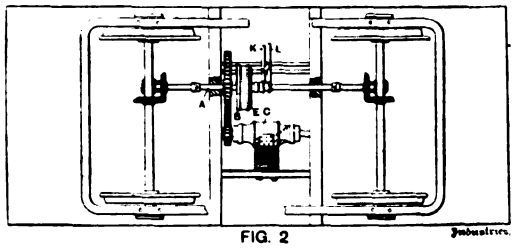

FIG. 2.

pinions F^1 gearing with D, the other ends of the studs F being fixed to a disc G. Mounted upon the elongated hub of G is an internal gear H gearing with the pinions F^1. Suitable hand-brakes surround the disc E and the gear wheel H, which, by means of suitable levers, may be applied as desired by the car conductor. The outer faces of the hubs of the wheel H and the disc G are provided with teeth H^1 G^1 (Fig. 2), which mesh with similar teeth on sliding clutches I J, the former mounted on A and the latter upon the former, and operated respectively through levers K L. The method of operation is as follows:—If it be desired to throw the shaft into gear so that it shall revolve in the same direction as the wheel B, the brake on E is applied so as to bring the disc G to a stop, and the clutch I is thrown into gear. The brake on E is then released, and the brake on H applied, the result of this being that the internal gear H is brought to a standstill, and the driven pinion D continuing to revolve, the idle pinions F^1 are dragged around between the two gears, and the disc G and the shaft A are given a rotation in the same direction as the disc B, but at a considerably less speed. If it is desired to bring A to a standstill, the brake on H is released. The internal gear H will then begin to revolve, and the brake wheel E become stationary. If it be desired to give the shaft an opposite rotation to that of the wheel B, the clutch I is withdrawn, brake on H then applied (brake on E being released by the same movement), clutch J is thrown into gear with H, and the brake on H released and the brake on E applied. This brings the brake wheel E and the disc G to a standstill, and the idle pinions F^1 are held on stationary bearings. The continued revolution of the driven pinion D causes the idle pinions to revolve in the opposite direction, which motion is transmitted to the shaft A through the clutch. The inventor also describes a modification of the above arrangement. Nine claims are made. —No. 14194. September 9th, 1890. 8*d*.

Brick Making Machines.—*S. Witt, Southampton.*—The inventor forms a machine for the above purpose as follows:—A wheel of suitable diameter is journalled in suitable framework, and has formed in its periphery recesses of a length, width, and depth similar to the bricks to be pressed. The bottoms of these recesses or moulds are movable, one bottom being connected to the bottom of the mould formed at a diametrically opposite position in the wheel. The length of these rods connecting the pairs of movable bottoms is such that whilst one bottom is situated at the lower extremity of its mould the other bottom will be situated at the upper end of its mould. Above this wheel a "pug mill" is placed wherein the clay is prepared, and when so prepared is pressed down a shoot, of a size and shape similar to that of the moulds in the wheel, into the said moulds by means of a plunger working within the chamber of the "pug mill." Beneath the wheel a horizontal endless band runs on suitable rollers upon which the bricks are delivered from one mould as the clay

Digitized by Google

is pressed into the mould placed in a diametrically opposite position in the wheel. Claims: (1) In a brick and tile-making machine the mode or method of moulding bricks and tiles in a revolving drum or wheel, as described; (2) a brick and tile-making machine constructed substantially as described.—No. 5180. April 3rd, 1890. 8*d*.

MACHINES FOR MAKING WIRE MATTRESSES.—*C. H. Hard, O. G. Franks, & A. E. Loomis, all of Oneida, New York State, U.S.A.*—Referring to the annexed illustrations Figs. 1 and 2 are side elevations, Fig. 3 is a plan, and Figs. 4 and 5 details of a machine, constructed on the principle of this invention, and for the

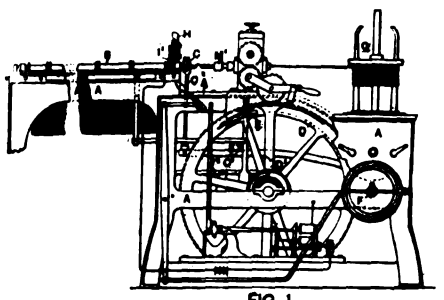

FIG. 1

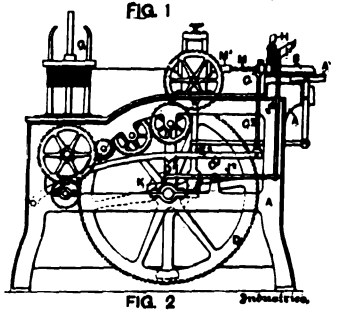

FIG. 2

Industries.

above purpose. Sliding in an elongation of the framework A is a slide A^1 having a longitudinal slot therein, on each side of which are the two grooved rollers B for supporting the mattress as it is formed. These rollers are geared together, and are revolved by means of a ratchet wheel on the end of one of them, into which engages a pawl or a lever C actuated through levers C^1 C^2 from a cam D^1 on the wheel D. The slide A^1 is given a slight reciprocating motion by means of levers E E^1 E^2, the latter of which is moved in one direction at each revolution of the wheel D by means of a suitable arrangement of cams on the end thereof, which are engaged by a cam on D. The wheel D derives motion from the main driving shaft F, as also do the reels G on which the wire is wound, and from which it is fed to form the mattress. These reels are geared with F by means of suitable intermediate frictional gearing so arranged that the speed of the reels may be regulated as desired. At the end of the rollers B is a bracket H (Fig. 4), in which is fixed the fixed knife I and the movable knife I^1, the latter being actuated through levers J J^1 J^2 from a cam K on D. In a line with the axis of the space formed by the opposite grooves of the rollers B is the wire-threader M around which the wire, after being forced by means of feed rollers L through the helical die M^1, passes to the space between B. The rollers L are driven from D, part of which is cut away (Fig. 5) in order that the said rollers may not be actuated during a certain period of the operation of the machine. A suitable automatic electric stop mechanism is also applied to stop the machine should the spirally formed wire not take its proper course. The described mechanisms of the machine are so arranged in relation

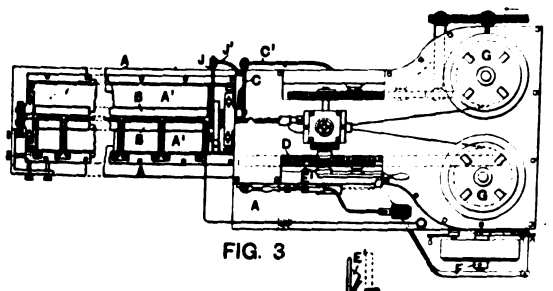

FIG. 3

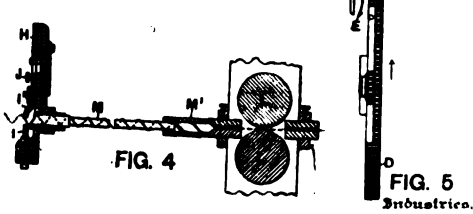

FIG. 4

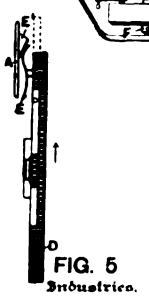

FIG. 5

Industries.

to each other that, in the process of weaving the mattress, the feed-rolls L draw the wires from the reel under the proper tension, and are passed through the twister M^1 which imparts a spiral form to the wires. The wires thence pass to the threader M which guides and pushes them into and along the space or channel between the rolls B B above the axis thereof, and at the same time imparts a rotary motion to the wires, the rolls B B remaining stationary. When the wires have thus been carried along between the rolls B B to a distance equal to the length of the mattress to be woven, the feed-rolls L automatically stop, and during this time of rest the pawl on the lever C turns the rolls B B sufficiently to carry the aforesaid wires slightly below their previous position without losing hold thereof, and then the knife I^1 descends and severs the wires. At the same time the sliding frame A^1 is moved slightly longitudinally, and thereby the upper helices of said wires are carried out of range with the wire held in the threader M. By the time this is effected the feed rolls L are again set in motion, and the coiled wires, which are then passed along between the rolls B B, intertwine with the upper helices of the wires held between the rolls as before stated. In this manner each pair of successive wires intertwines with the last preceding wires, and each turn of the rolls B B allows a corresponding portion of the woven fabric to drop. The fabric thus woven is supported in a suspended position from the rolls, and passes down through the slot in the elongation of the frame A. Ten claims are made.—No. 17717. November 4th, 1890. 8*d*.

PUNCHES AND DIES.—*F. B. Bristol, Waterbury, Connecticut State, U.S.A.*—The invention has reference to dies and punches for cutting sheet metal annular or serrated blanks for belt fasteners. The dies and punches for this purpose are formed of a number of separate sections joined together by bolts passing transversely through them, or other suitable means, each section being provided with cutting edges tapered uniformly to a point, the combined sections forming a continuous angular or serrated cutting edge. In this manner better cutting edges are obtained, and in case of breakage the broken part may be renewed without necessitating the formation of a new die or punch. Claims: A die or punch for cutting belt fastener blanks composed of a number of sections, each provided with cutting edges tapered uniformly to a point, said sections being jointed together by means of bolts to form a continuous serrated cutting edge, substantially as described.—No. 20907. December 23rd, 1890. 6*d*.

COMPOUND STEAM ENGINES.—*W. H. Allen, R. Wright, & R. W. Allen, all of London.*—Fig. 1 in the accompanying illustrations is a longitudinal vertical section, and Fig. 2 a horizontal section through the cylinders of an engine constructed according to this invention. A is the high-pressure cylinder and B the low-pressure cylinder, and C is a steam jacket surrounding A the central valve D D^1, and part of the low-pressure cylinder B. High-pressure steam is admitted into the jacket C through the steam pipe at E, and from this jacket the steam enters the steam chest F, through a port G, between the two pistons D D^1, which form the central valve. The piston valves D D^1, which are connected together by a rod H actuated by eccentrics in the usual manner, fit and

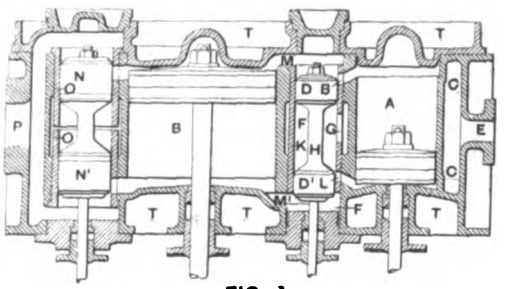

FIG. 1

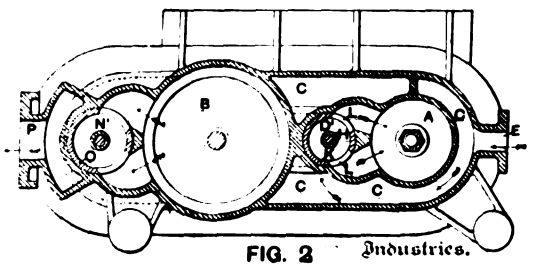

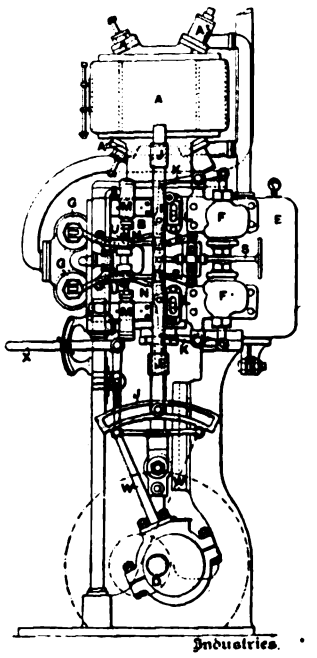

FIG. 2

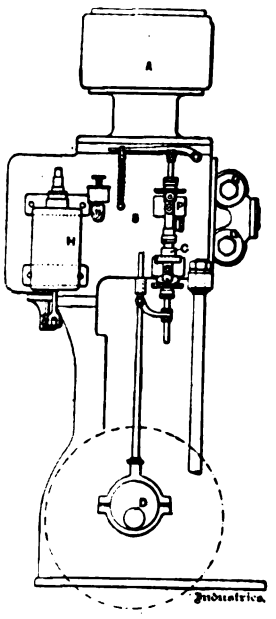
Industries.

work in a case K provided with ports L, by which the steam between these valves is admitted as desired to the two ends of A alternately, is cut off at the determined times, and is allowed to pass directly to the corresponding ends of B. The inner edges of D D^1 serve to cut off the steam admitted to A, and their outer edges uncover the same ports and allow the steam to pass from the ends of A alternately into the ends of the steam chest F, and thence into the ports M M^1, leading direct into the ends of B. B is provided with a separate exhaust valve also consisting preferably of two piston valves N N^1 working in a casing O, the ends of which communicate with the exhaust pipe at P, and are operated by an eccentric in the usual manner. The exposed parts of the engine at T are preferably packed or covered with asbestos or other suitable non-conducting material. Claims: (1) The valves D D^1 in combination with the valves N N^1; (2) the steam jacket C, admission pipe E, port G, valve casing K, valves D D^1, ports L and M M^1, and exhaust valve N N^1, all arranged as described and illustrated.—No. 4892. March 28th, 1890. 8*d*.

PRESS DIES.—*S. Fox, Leeds.*—The invention relates to the construction of dies for pressing steam-boiler flues or other like tubular articles. For this purpose the female die is formed in two parts, the lower part being internally of the size to which the flue or tube is to be drawn. The upper part, which is bolted upon the lower part, and is made in two parts so that it can be easily removed, is formed internally with a tapered hole tapering downwards so that the lower end is of a similar size to that of the hole in the lower part. The surface of this tapered part is concentrically grooved, so that, as the heated disc of metal is pressed into it by the male die, it is successively acted upon by the ridges. The male die is made collapsible, and is composed first of a small circular punch, around which are arranged metal strips approximately triangular in cross-section, and held together by two steel rings, and between the projecting edges of these are three segmental pieces, which together form the die. The operation is as follows:—A disc, with a central hole formed in it, having been heated, is placed over the female die, and the male die caused to descend until only a small flange of metal remains in the upper or tapered part of the female die. This upper part is then removed, and by means of a suitable collar on the male die, that part of the metal standing above the surface of the remaining portion of the female die is pressed flat upon the said surface, so forming a flange. By now causing the punch in the centre of the male die to descend, the end of the tube is forced out, and the male die is then removed by first removing the central punch, the steel rings, the triangular pieces, and the segmental pieces in the order named. Claims: The arrangement substantially as described.—No. 4640. March 25th, 1890. 8*d*.



HOT-AIR ENGINES.—*W. de la Touche, Paris, France.*—In the accompanying illustrations Fig. 1 is a front elevation, and Fig. 2 a rear elevation of a marine engine constructed on the principle of this invention. A is the air pump, around the cylinder of which is formed a reservoir for containing liquid hydrocarbon

Industries.

FIG. 1.

supplied to the injection pump C, operated from the main crankshaft D. A^1 are the air suction valves of A, and A^2 the force valves through which and suitable pipes the air is forced into a reservoir E in connection by means of valves F with the main cylinder B, the exhaust from the latter escaping through valves G. A hand-pump H is provided for charging E when starting the engine. The introduction of the air and petroleum is effected by means of a rod I having a click, which rod is actuated by a "Stephenson" link motion J sliding in guides J^1. This rod actuates at the same time (1) the valves F for the introduction of air into the cylinder, by acting for a certain time upon the levers K through the medium of the small tappet which allows the said valves to fall back when the angle for the lift has been described, and guides L for the introduction of air; (2) the slides M for the admission of the petroleum, by means of levers N pivoted at N^1, and upon which act the arms O of a lever P pivoted at P^1 to I. Above and below this lever N are arranged the tappets Q fixed at the ends of the bell-crank levers R pivoted at R^1. By operating the hand wheel and screw S, the nut T is moved backward or foward as desired, thereby effecting the forward or backward movement of the pins U on the bell-crank lever R. By this means the tappets Q are operated, and they are encountered by

Industries.

FIG. 2.

the arm P. When this arm encounters a tappet Q the corresponding arm O of the lever P releases the arm N; (3) the outlet valves G are likewise actuated by the rod I by means of the levers U pivoted at U^1, and provided with rollers U^2, which are alternately raised by the projecting parts V on the rod I. The ignition is produced in the cylinder by an electric spark. The link motion J is for the purpose of keying two eccentrics W symmetrically upon the shaft so as to keep one-fifth of a revolution behind the crank. By means of the lever X the motion may

Digitized by Google

be changed. Claims: An engine worked by gradual expansion and actuated by the ignition of liquid petroleum, the heating material employed, when introduced into the engine cylinder, being at a pressure equal to the pressure in the interior of the cylinder at the time of the ignition, the air which is to be admitted to be expanded being introduced with or without pressure previous to the heating material, and the construction of engines in accordance with the principle above set forth.—No. 2384. February 13th, 1890. 8*d*.

APPARATUS FOR MEASURING GRAIN.—*M. Cashin & G. Shanklin, both of New York, U.S.A.*—This device is for the purpose of measuring grain or other such dry matter, and for delivering it into barrels or other suitable receptacles. Fig. 1 in the accompanying illustrations is an end elevation, and Fig. 2 a side elevation partly in section of an apparatus for this purpose. Supported

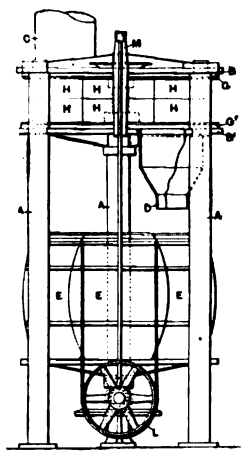


FIG. 1.

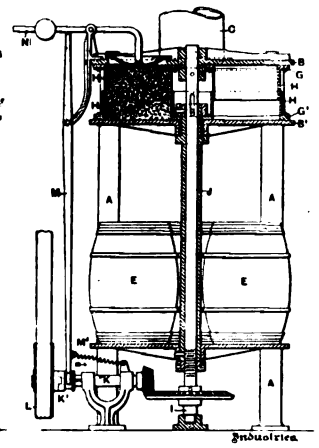

FIG. 2.

on columns A, and at a suitable distance from each other, are two plates B B¹, the upper of which has formed on one side of it an orifice communicating with the charging spout C, and the lower having an orifice communicating with the delivery spout D, through which the measured material is delivered into the barrels E placed upon a turntable F. Between B and B¹ are situated two plates G G¹, each carrying a half of the four telescopic measures H, the upper of which is connected direct and revolves with the vertical shaft I. The lower plate G¹ is fixed to a sleeve J capable of longitudinal movement on I, so that the capacity of the measures H can be varied. As the plates G G¹ revolve together with measures H, the latter will be automatically filled from C and discharged from D, as will be understood. Fixed on the intermediate driving shaft K, from which I is driven, as shown, is a clutch K¹, by means of which K is connected with the driving pulley L. This clutch is operated in order to stop the motion of the machine when the supply of grain is exhausted, as follows:—The lower end of a lever M pivoted, as shown, tends by means of spring M¹ to throw K¹ out of engagement. The other end of M, however, engages a notch on a lever N, so preventing this action until the lever N is allowed to be raised at that end by the falling of its opposite end (formed as shown in Fig. 2) into one of the measures H through an orifice in B. Claims: (1) In a grain-measuring device, the combination of the turntable G upon the shaft I and having one half of the measures H, the turntables F and G¹ upon the sleeve J, which rotate with said shaft and are adjustable vertically, said turntable G¹ having the other half of the measures H, the stationary floor B, and the vertically-adjustable floor B¹, said floors and turntables having orifices that communicate respectively, with charging and delivery spouts C and D, as set forth; (2) in a grain-measuring device, the combination, with the revolving and perforated turntable G, having the attached measure H, and with driving mechanism having clutch-connection with a fast and loose pulley of the governor, as described.—No. 15745. October 4th, 1890. 8*d*.

TUBE CUTTER.—*C. Wicksteed, Kettering, Northampton.*—The cutter embraced by this invention is for the purpose of cutting out boiler and such like tubes from the interior. In the annexed illustrations, Fig. 1 is a longitudinal section and Fig. 2 a cross section on line Z Z of a tool for this purpose. The body A, formed as shown, carries, and is adapted to be turned by, a ratchet

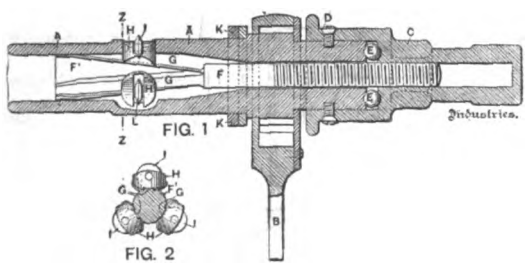

FIG. 1

FIG. 2

handle B. The cap C is secured to A by means of screws D running in a groove in the latter, balls E being placed between the ends of each to take the thrust of A. Screwed into C and passing freely through A is a screw F, the outer end F¹ of which is tapered as shown, and has formed on its surface dovetailed ways G upon which slide the holders H of the cutters I. From the above it will be seen that, by revolving C in a suitable direction, the screw F can be drawn into the body of A or forced towards the end thereof, so causing the holders H to be forced outwards from or withdrawn into A. Claims: In a tube cutter (1) a cutter which is withdrawn into the body of the tool as described; (2) a tapered bolt F F¹ having dovetailed faces G for the purpose described; (3) the combination with a tapered bolt F F¹ having undercut working faces of a cutter box H adapted to carry the cutter and also dovetailed to engage with the faces of the bolt as and for the purpose described; (4) the combination with the cutter operating bolt of a body extension A¹ for the purpose of serving as a guide for and also for protecting the said bolt; (5) the combination and arrangement of parts constituting the complete tube cutter substantially as described and illustrated. —No. 2274. February 12th, 1890. 6*d*.

ELECTRICITY.

SWITCHES.—*A. J. Kingdon, London.*—The switch embraced by this invention is a double-pole switch, for use with high tension currents. This is constructed in the following manner:—A long roller of wood or other insulating material is pivoted in suitable brackets fixed to the base of the switch. Near the ends of this roller metal arms or springs project, which make contact with spring or other metallic pieces fixed to the base, which is preferably of slate. A third radial rod fixed to the centre of the roller has pivoted to it a second and long rod, by the operation of which the spring arms, which are preferably of a U shape with the ends turned outward, can be brought in electrical connection with the contact pieces to which the circuit wires are connected. Claims: The combination in an electrical switch—(1) Of a roller of insulating material with one or more metal contact arms; (2) a roller carrying a metal contact arm and an operating lever pivoted to an arm attached to the roller; (3) a roller carrying contact arm with an operating rod at right angles to it and pivoted or geared to it; (4) in combination with a switch-board of horizontal rollers operated by vertical rods; (5) the improved switch and switch-board as described.—No. 4275. March 19th, 1890. 8*d*.

ARC LAMPS.—*A. Gay, Brighton, & R. Hammond, London.*—The invention relates to the use of two motors for regulating the positions of the electrodes in arc lamps. One motor is traversed by the main current, and is so proportioned in relation to the resistance against which it works that it remains at rest when the normal current is flowing; when the current increases above the normal point this motor commences to rotate and draws the carbons apart. The second motor is placed in a shunt circuit around the arc, and is likewise so proportioned that when there is a normal difference at the terminals of the motor it is stationary. When the difference of potential increases, however, the motor rotates and moves the carbons nearer to one another. The motors are arranged on the opposite ends of a horizontal shaft journalled in the upper part of the lamp frame. In the centre of this shaft are arranged two pulleys, to which are connected two cords attached at their other ends respectively to the upper and lower carbon-holders, in the form of slides sliding on two or more vertical rods, and so disposed that the rotation of the shaft causes the carbon-holders to slide in opposite directions, so that if the shaft is revolved in one direction the slides move towards one another, and if in the other direction from one another. Claims: (1) An electric arc lamp, in which the position of the carbons is regulated by two rotary electric motors, one of which is traversed by the main current of the lamp and is in series with the carbons, and the other of which is in a shunt circuit around the voltaic arc, the two motors being so arranged that the rotative force of the one is opposed to that of the other, and balances it when the voltaic arc is of its normal length; (2) the construction of electric arc lamps substantially as described.—No. 4991. March 31st, 1890. 8*d*.

WELDING METALS.—*W. P. Thompson, London.* (*C. L. Coffin, Detroit, Michigan State, U.S.A.*)—According to the invention the welding operation of metals by the aid of electricity is performed under water. For this purpose a trough is used, in one side of which is formed a stuffing box. Through this works a slide, carrying on its inner end a suitable clamping device to which one of the wires of the electric circuit is connected. This slide, which is insulated from the trough, is made hollow, so as to receive the projecting end of the rod or other bar to be welded, which bar is held in the clamping device, and a suitable length projects beyond said clamping device. The slide is opened at its inner end so that water can circulate in the interior thereof. Another clamping device is fitted to a bracket on the opposite side of the box and holds the other part of the rod to be welded, the other wire of the circuit being connected thereto. A screwed spindle is attached to the outer end of the slide and passed through a screw-threaded hole in a bracket projecting from the side of the trough, so that, by suitably revolving the screwed spindle, the slide, and so one rod, can be advanced towards the other rod. Claims: The method described of electric welding consisting in immersing articles to be welded in water, heating them electrically, and pressing them together to form a weld. The apparatus for welding metals electrically combined and arranged substantially as described.—No. 15,455. September 30th, 1890. 6*d*.

CHEMISTRY.

MANUFACTURE OF BORAX.—*The Borax Company, Limited, London.*—The process embraced by this invention consists first of a preliminary purification of borate of lime, obtained by one or more washings of the ore in a solution containing carbonate of soda in a quantity equivalent to the sulphate of lime to be eliminated. The liquid is then drawn off, and carries with it the sulphate of soda that has been produced, leaving a mixture of borate and of carbonate of lime. To this purified mass a quantity of carbonate of soda necessary to convert the borate of lime into a basic borate of soda is added, and the mass diluted just sufficiently to enable it to be poured; secondly, it is introduced into an air-tight metallic recipient, capable of supporting a pressure of several atmospheres, which is then connected with a boiler. The steam throws the mass into violent agitation, the pressure, and in consequence the temperature, rises rapidly, and all the borate of lime is rapidly converted into a basic borate of soda and carbonate of lime. The contents of the recipient, whose density is about 60° Bé., are then forced into a vat, where the amount of boracic acid necessary to convert the basic borate of soda into borax is added, and in which they are mixed with the mother liquors of preceding crystallisation of borax. Claims: (1) In a process for manufacturing borax from borates of lime and boracite, the preliminary purification of the borate and elimination of the foreign matters and salts which accompany it, and more particularly of the sulphate of lime, as described; (2) the treatment of borate of lime at a high pressure, as described. —No. 2526. February 17th, 1890. 6*d*.

MISCELLANEOUS.

RAMRODS FOR ORDNANCE.—*T. H. Howard, Charlton, & J. M. Lapping, East Greenwich.*—The inventor's object is to provide a joint, by means of which the several parts of the ramrods or sponging rods of large ordnance may be readily and speedily jointed. For this purpose the inventor forms on one end of one of the parts a T-shaped metal head adapted to pass into a socket on the end of the other part of the rod, and when slightly turned the projecting portions of the T part pass over suitable ledges in the female part. If desired, a spring or sliding catch or bolt in one part may pass into a hole or recess in the other part, so preventing the rotation of one in the other when in use; or the two parts of the joint may be inclined on the faces which come together, so that, when turned one on the other, the two parts will jam tightly together. Claims: Ram or sponging rods for ordnance constructed in two or more lengths, the one length preferably having a T-shaped head, and the other a corresponding opening for the reception of the T head, which parts, when turned, will lock or jam together, and having a spring catch or bolt to prevent rotation thereof, substantially as described.—No. 948. January 18th, 1890. 6*d*.

SHIP SIGNALLING APPARATUS.—*M. Chadburn, Liverpool.*—The accompanying illustrations are of a receiving apparatus, constructed according to this invention, and for the purpose of receiving orders from the bridge, Fig. 1 being a part front elevation, Fig. 2 a side sectional elevation, and Fig. 3 details. Running in a frame-work A is a spindle B, actuated by means of a wheel B¹ and a chain or other means from the bridge. Loose on the end of B is a sleeve C (Fig. 3), carrying on its outer end the pointer D, working over a dial E, and on its inner end a toothed segment F on the upper surface of which a wheel F¹ is pressed by a spring F². This sleeve can revolve around B, subjected, however, to the limit of the slot C¹ in the former, in which works a pin in the latter. Two toothed wheels G G¹ are also carried on B, and actuate by means of bell-crank levers H H¹ two pairs of spring strikers I I¹, so causing them to strike the gong J. In action, when the shaft B is rotated by the actuation of the wheel B¹ from the transmitter, one of the teeth of the wheel G or G¹, as the case may be, actuates the short vertical end H² of the bell crank H or H¹, and draws one of the hammers down, and as soon as such tooth passes over or leaves such end H² the hammer is released and strikes the gong; then on the further stroke of the shaft, that is in its latter portion, the other

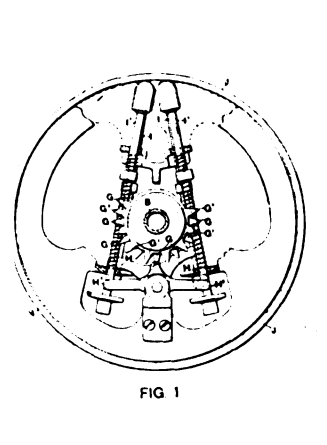

FIG 1

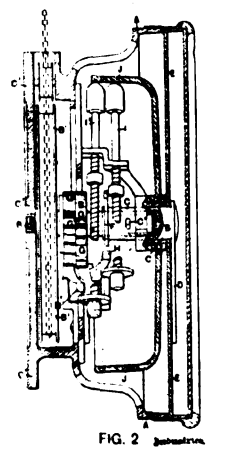

FIG. 2

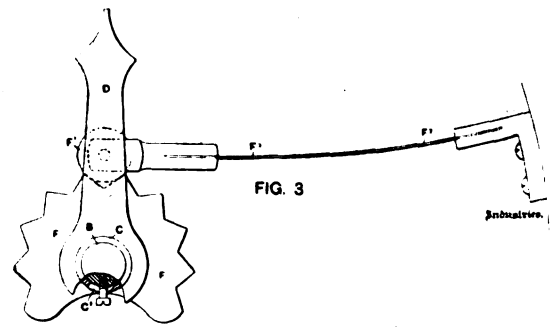

FIG. 3

toothed wheel comes into action with the other bell crank, and it is similarly worked, and the gong is sounded simultaneously—or nearly so—as the pointer moves into its correct and central position over the order on the dial it is intended to move it to, this latter movement of the pointer being effected automatically by means of the roller pressing on the toothed segment. Should, however, through mechanical defects or causes, the wheel B not receive from the transmitter enough movement, on some occasions, to cause the gong to be sounded as the pointer moves to its central position over the order to which it is intended to be moved, the sound given by the hammer first actuated will have called attention to the change of order. Six claims are made.—No. 1143. January 22nd, 1890. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

THE WEST HIGHLAND RAILWAY.

MESSRS. FORMANS & MACCALL, GLASGOW, ENGINEERS; MESSRS. LUCAS & AIRD, LONDON, CONTRACTORS.

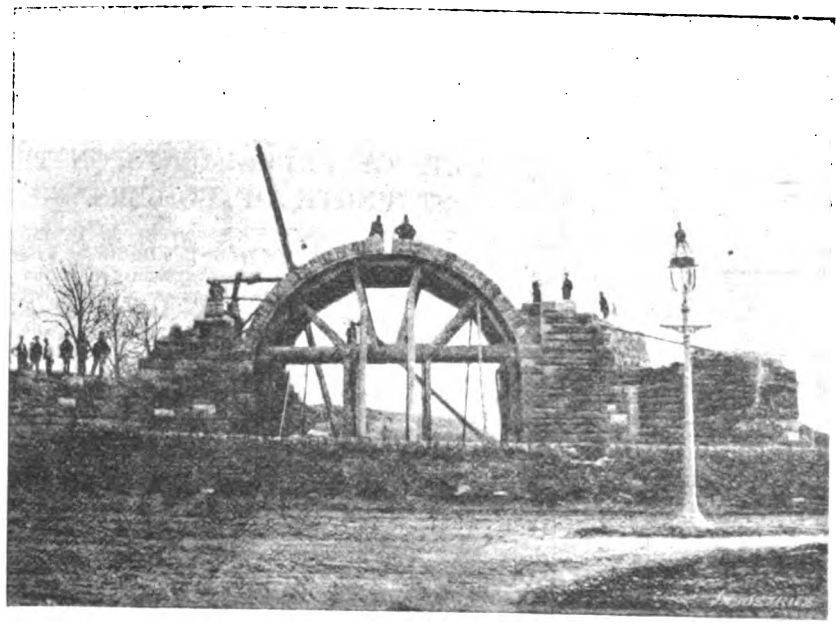

FIG. 5.—BRIDGE OVER PRIVATE ROAD AT 53 CHAINS.

FIG. 6.—HELENSBURGH CUTTING: SOUTHERN ENTRANCE.

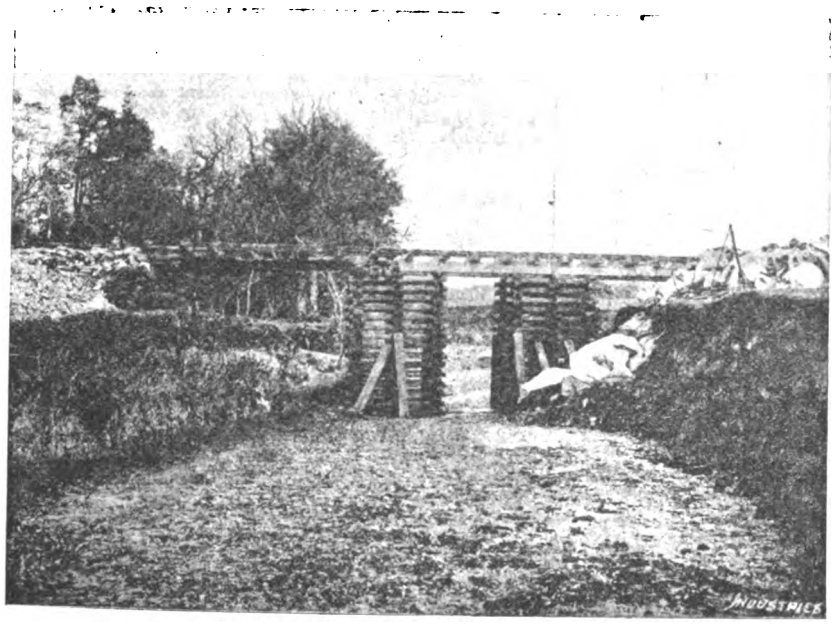

FIG. 7.—TEMPORARY BRIDGE NEAR ARDENCAPLE BURN.

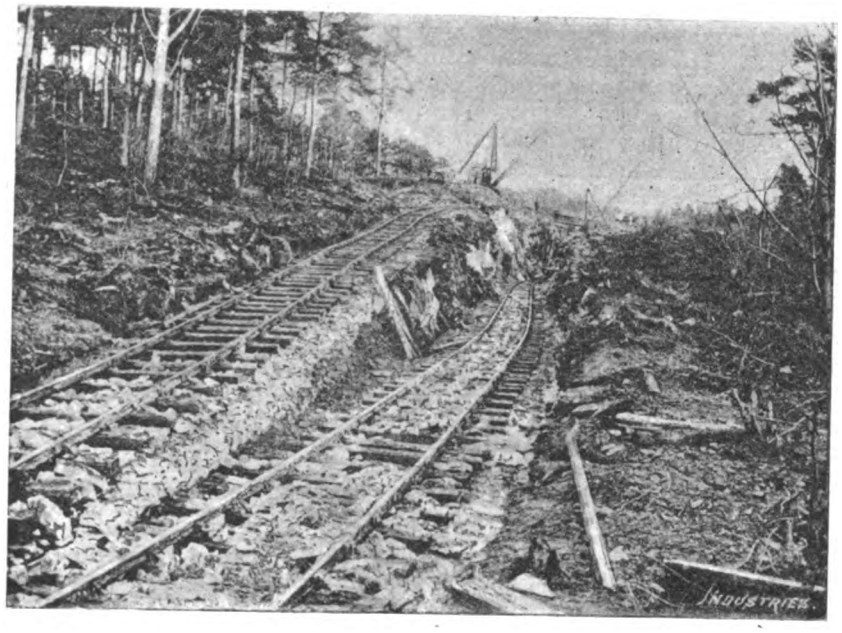

FIG. 8.—ROW CUTTING: NORTH END, LOOKING SOUTH.

THE WEST HIGHLAND RAILWAY.

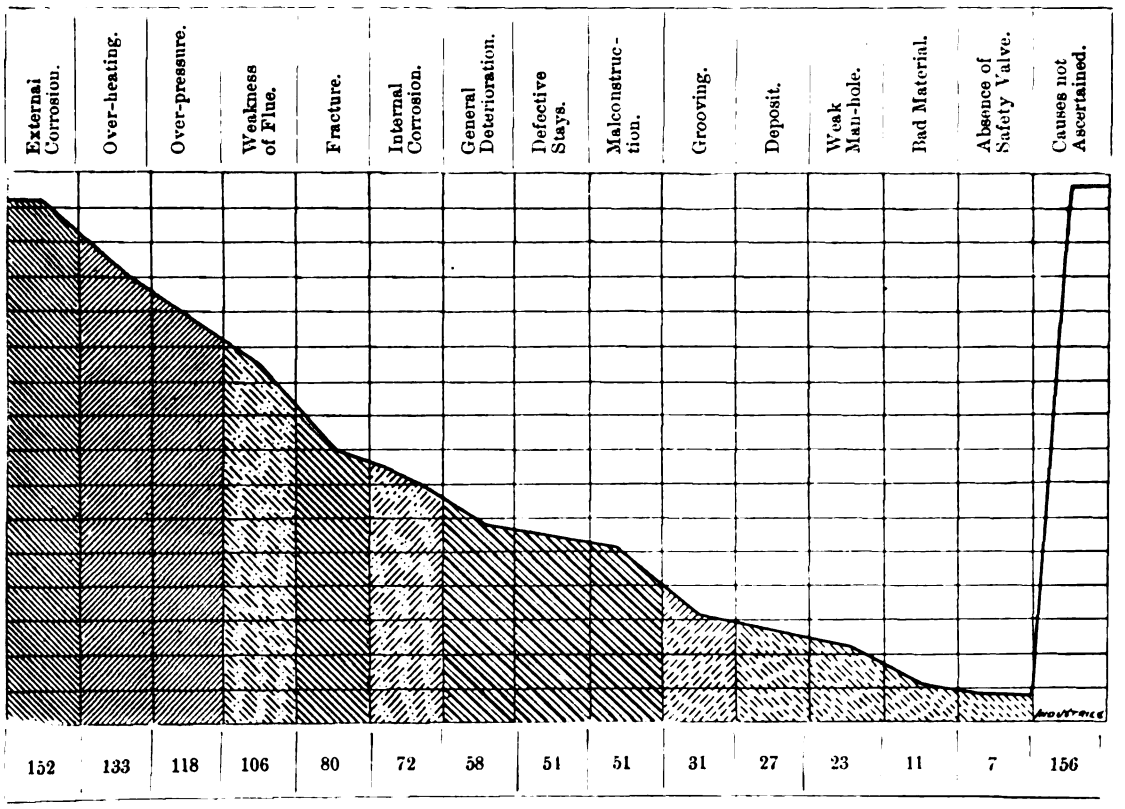
II.

THE railway now under construction between Helensburgh on the Clyde and Fort William received some general notice in our recent article (see *Industries*, Vol. X., page 12), when we gave the most salient features of this important undertaking, and dwelt more particularly with the section extending from Crianlarich to some four miles beyond Tyndrum, illustrating our description by views portraying the most interesting and characteristic works being carried out at this point.

In the present notice we pass to the most southern section of the railway under consideration—viz., the portion from Helensburgh to about two miles beyond Whistlefield—and give a series of views extending from the commencement of the line to about the middle of this section, leaving the remainder to be dealt with in later issues. The line, as already stated, commences at Craigendoran, near Helensburgh, where it forms a continuation of the North British Railway, and, running up the eastern end of Helensburgh, reaches the high ground at the back of the town, and, taking a curve westward, skirts the northern boundary of that pleasant watering place. The line then passes along the hillside to Gareloch Head through pleasantly wooded and highly picturesque country, affording at every point charming views of the Gare Loch, with the beautiful peninsula of Rosneath on the opposite shore. The loch is never lost sight of until Whistlefield is reached.

Considering in detail the leading features of the first portion of this section, which form the subject of this notice, the line commences in bank to the east of Craigendoran Station; Drumfork Burn is then passed, a 7ft. culvert being provided for the passage of the burn, and the Dumbarton Road is crossed by a girder bridge, 35ft. on the square, the span on the skew being about 55ft., the angle being 39°. The line, still in bank, crosses a private road leading to an adjoining mansion-house by a masonry arch bridge, having a span of 30ft. (see Fig. 5). A diversion of the private road is being carried out at this point. The bank is well advanced towards the Dumbarton Road, whilst the arch bridge already mentioned, and which occurs at 53 chains, has made good progress, the arch being turned and the lining walls practically completed. The bridge has been built from stone quarried near its site, and presents a handsome and massive appearance. The bank already referred to, as extending from the commencement of the line to about two chains beyond this bridge, is about $\frac{7}{8}$th of a mile in length, and has a maximum height of about 30ft. A small cutting of soft material, some two chains in length, is then passed, which is completed, and the line again runs into bank up to 1 mile 20 chains, the greatest depth of this bank being about 20ft. At 1 mile 24 chains a steel girder bridge carries the old Luss Road over the railway, being approached on either side by raised banks. The cutting at this point is a small one, and calls for no special remark beyond the fact of its completion.

At 1 mile 36 chains the large cutting commences, which forms one of the leading features of the section now under consideration. This cutting extends for nearly a mile—viz., from 1 mile 34 chains to 2 miles 23 chains—and is crossed by several bridges, &c., which may be briefly enumerated. At 1 mile 48 chains a fly-over bridge, 30ft. wide, carries a private road over the railway, whilst at 1 mile 54 chains a water trough, constructed of steel, carries a stream over the line, whilst at 1 mile 72 chains a culvert carries the burn there met with under the railway, a siphon being also built to convey water to the mill lade.



The Helensburgh goods and passenger stations are also placed at this point in cutting, and considerably increase the amount of material to be excavated, and the following bridges span the cutting towards its northern end:—At 2 miles 20 chains a steel girder bridge carries the Luss Road across the railway, being 40ft. in width and having a span of 30ft.; at 2 miles 9 chains a foot-bridge, in connection with the Helensburgh passenger station, is carried across the line, and several accommodation roads, forming one road 60ft. in width, on the south side of the railway; whilst at 2 miles 9 chains a public sewer is met with, and, being lowered, is duly carried under the line.

This important cutting is being entered in three sections (Fig. 6 showing the southern entrance) the

DIAGRAM SHOWING THE CAUSES OF BOILER EXPLOSIONS.

By B. H. Thwaite, A.M.Inst.C.E., F.C.S.

Number of Explosions from the Causes Enumerated Above.

material met with being rock covered by a thick bed of soft material. The rock is being dealt with by blasting and quarrying. The Helensburgh cutting extends, as already stated, for about a mile, and has a maximum depth of over 40ft., whilst the total quantity requiring to be excavated, including that to be removed to form the site of the Helensburgh passenger and goods stations, is estimated as about 160,000 cubic yards. Work is being vigorously maintained on all three sections of this important cutting, and the excavation is well advanced.

The finished permanent way, we may remark, which runs up to this point, as the completed portions of the line, here joins an overland route, passing along the edge of the cutting, this temporary road being laid with the material to be subsequently employed in the permanent way, and consisting of 75lb. steel rails and 36lb. chairs, service line being one of the smoothiest and most carefully laid it has fallen to our lot to travel over; and, by freedom from casualties, has doubtless already amply repaid the care bestowed in its construction.

Returning to the termination of the great Helensburgh cutting, which extends 2 miles 23 chains, we pass to a short bank running to 2 miles 32 chains, and 45ft. in height, over a 4ft. culvert; a bridge, 30ft. span, passing under the railway at 2 miles 29 chains. A small cutting then follows, and at 2 miles 60 chains a bridge of 30ft. span occurs, together with a 3ft. culvert, provided for the passage of the Ardencaple Burn. Fig. 7 illustrates the temporary bridge provided at this point for the passage of the overland route, and is illustrated as portraying a type of construction occurring on this section. The view readily explains itself, the piers being composed of creosoted sleepers stacked in cross-layers. This bridge is succeeded by a shallow cutting; then various minor banks and cuttings alternate up to 3 miles 34 chains, where a 3ft. culvert has been built, and one chain further on—viz., at 3 miles 35 chains—the important Row cutting commences, running out at 3 miles 75 chains. This cutting, which forms the other leading feature of the length now under consideration, is entirely through rock, and is being entered, like that at Helensburgh, in three sections. Air-compressing plant has been erected at the northern end of the cutting, and rock drills are employed at all points. Row Station occurs in this cutting.

Fig. 8 illustrates the Row cutting. A bank succeeds this cutting, and passes over a culvert carrying the Row water-pipes, an accommodation bridge occurring at 4 miles 6 chains. This is followed by a small cutting, and then bank again occurs, extending from 4 miles 11 chains to 4 miles 23 chains, and 70ft. in height.

The girder bridges referred to in the foregoing description call for no special notice. Steel has been used throughout in their construction, and an average ultimate tensile strength of about 30 tons per square inch has been specified; whilst we are informed the maximum stress to which they can be subjected under any possible circumstances of severe loading does not exceed 6 tons per square inch. The girder work has been entrusted to Messrs. Findlay & Co., of Motherwell, the material being rolled in the district.

Cement concrete is being employed in bridges, &c., having a proportion of 5 to 1. The earth slopes throughout the undertaking are made 1½ to 1, whilst the rock is being cut to a slope of ¼ to 1. A considerable length of permanent way is already laid on this portion of the first section.

The contractors' headquarters are at Helensburgh, and a commodious depôt has also been established on this section near Helensburgh. Huts for the accommodation of the navvies employed on the undertaking are scattered at intervals along the line, in connection with which it may be mentioned that a large number of crofters from Skye and the other outer islands have been attracted to the line by the prospect of lucrative employment.

GRAPHICAL VIEW OF THE CAUSES OF BOILER EXPLOSIONS.

The above diagram, showing graphically the causes of boiler explosions as regards land boilers, is based upon an analysis of available reports of boiler explosions over a series of years. It was prepared by Mr. B. H. Thwaite for his lecture on steam generators delivered a short time back at the Yorkshire College Textile Society. The diagram shows in a striking manner that the causes are divisible into the following categories:—

1st,	Through the influence of	thermic action.
2nd,	„	„	chemical action.
3rd,	„	„	physical action.
4th,	„	„	structural defects.
5th,	„	„	defective supervision.

The diagram also shows clearly the necessity of using a form of steam generator not liable to corrosive effects, and points to the desirability of care being exercised in thoroughly draining the foundations of steam generators of the Lancashire and Cornish type, because by capillary attraction the water ascends through the flue walls until it reaches the shell plates of the boiler, and local corrosive action is at once set up, which continues insidiously destroying the safety margin of the plates. The action is probably accelerated by the alternate effects of dampness and the contact of heated gases, resulting from the stoppage of the boilers each week end. This diagram might with advantage be placed in the hands of all those who are responsible for the safety of steam boilers.

RESULTS OF EXPERIMENTS ON THE STRENGTH OF BOILERS.*

Last year the author brought before this Institution an argument intended to show that the present system of calculating the strength of boilers is erroneous, and proposed a new method. Since then he has made a series of experiments on the subject, the results of which he now desires to place before the Institution.

His previous argument was that it was unnecessary to make a boiler as strong as if it were an endless ring, and that the resistance, due to the connection between shell and ends, should be added to the circumferential resistance of the shell, in order to get the true strength of the structure. If this were true, the strength of boilers, especially of the marine type, would not be, as hitherto assumed, independent of their length, but would depend as much on their length as on their diameter. To test this, he made three small cylinders (see Figs. 1, 2, and 3, page 244) of equal diameter, thickness of plate, &c., differing only in length, and tested them to destruction by water pressure. Each of these drums was made of a sheet of $\frac{7}{16}$in. steel plate rolled to a circle of 26in. diameter, with one longitudinal single riveted joint. The ends were flanged outwards and riveted to strong end plates which were very strongly stayed, longitudinal and end joints were single riveted, pitch of rivets 1¼in., diameter of rivets ½in., diameter of holes $\frac{7}{16}$in., all drilled in place; percentage of plate in line of rivet holes, 55 per cent. of solid plate. The riveted joint was adopted because the only other alternative that occurred was a welded seam, and the author considered that a known weakness was better than an unknown strength. The single riveted joint was adopted, in order to keep the pitch of rivets small, and give the thin plate a chance of being water-tight with ordinary caulking. The end attachment was made in the style shown, to keep all the rivets outside, and avoid the necessity for any hand holes in end or shell.

Experiments.

Model No. 1.—The working pressure of all these models being, according to standard rule, 80lb., Model No. 1 was, after completion, tested and made tight to a test pressure of 160lb. before any measurements were taken. Five circles were then drawn round the shell as shown dotted in Fig. 1. These were marked off at the points *a*, *b*, &c., in order that the extension of joint might be observed separately from the extension of solid plate. Measurements were taken from *a* to *b* across the joint by a pair of compasses, and from *b* to *a* round the shell by a steel tape. Pressure was raised by means of a small hand test pump. Measurements of joint and plate were taken at various pressures, and are given in Table I., the pressure being reduced to 0 from time to time. Up to 600lb. pressure the model was not seriously strained; the leakage looked considerable, but the amount could not have been great, as an occasional stroke of the hand pump was sufficient to keep the pressure constant for a considerable time while all the measurements were made and checked and recorded. As the pressure rose above this, the leakage increased rapidly, and not more than 630lb. could be got with the hand pump. At this pressure the joint was evidently strained, but in other respects the model was not appreciably altered. The experiment was then stopped, the joints and rivets were all caulked and the model was carried into the boiler shop and connected to the hydraulic service pipes. Pressure was raised to 700lb. by a pair of steam pumps, but this could not be increased owing to leakage. Two other pumps were then coupled on, but were still unable to increase the pressure, the model still remaining not seriously damaged. A connection was then made with the accumulator, and the pressure rose to 730lb.; the form of the model visibly altered, and again the leakage overpowered the whole supply of water. The form taken by the model is shown by the dotted line in Fig. 1, which shows a decided hump near to each end and a slight hollow in between.

Model No. 2.—Was tested in much the same manner as No. 1. The leakage overpowered the hand pump at 550lb. pressure; joints and rivets were then caulked and model connected to hydraulic service pipes. In this case four pumps were discharging into the accumulator, and the pressure was admitted from thence to model. Pressure was allowed to increase gradually till it reached 680lb.; the model then visibly changed form, and the leakage overpowered the water supply. The form taken is shown in Fig. 2, which closely resembles that of No. 1.

Model No. 3.—This model had only three lines drawn on it, and had not been tested previous to the experiments; it was therefore thought advisable to caulk up some slight leaks which showed themselves at 250lb. pressure. This was done; the pressure was then increased by the hand pump to 550lb., when the leakage balanced the supply of water. The model was then caulked all over and connected to the accumulator. The pressure was raised quickly to 800lb.; at that pressure the joint broke with a loud report. The form taken by the model is shown in Fig. 3, the two outer curves showing the form taken by the plate all round the circle, except in the immediate region of the joint, where the barrelling is most pronounced, as shown by the curve at centre of Fig. 3. A view of the ends of the models is given in Fig. 4.

All the facts and figures observed during the experiments are given in Tables I. to V. and in the illustrations. But facts and

figures are of little use and may be very misleading until the laws which govern them are understood. And if the author could give a clear and definite explanation of the results of his experiments, he would feel that he had done some service; but he fears that he may have only succeeded in unsettling established principles without being able to offer anything definite in their place. Although he has not been able to deduce a clear relation between pressure and strain, yet, as he has given a good deal of attention to this problem, and made some steps towards its solution, he has recorded the partial solution worked out by him. As the arguments are too speculative to affect practical work he has given them in an Appendix (which we hope to publish in our next issue); and he now only proposes to notice a few facts, to prove that there is a problem to solve, and attempt to extract some practical guidance from these experiments.

In the first place he would like to call attention to the points that appeared to him to be most significant. No. 1 was the first model tested, and he was surprised to find that the first measurable alteration was a contraction at the joints. This remarkable result is not easily reconciled with the theory that the shell was subject to a uniform tension and to no other strain. He had searched through many records of tests to find if this was unusual, but could find very little directly bearing on it. Some few facts pointed to a similar action in other cases, but they were too indirect for quoting. The next point worthy of notice is the very high pressure, 730lb. to the inch, sustained by this model. On the endless ring hypothesis the elastic limit of the joint would correspond to a pressure of 328lb.; that of solid plate with a pressure of 596lb. Those who are practically familiar with the sudden and rapid elongation which occurs when steel of this character reaches its elastic limit will probably agree that, in this experiment, that limit had not been reached (at any rate in the plate) till the pressure was about 700lb., and had not been much passed at 730lb. Another curious fact was, that the joint, except by leakage, did not appear to have suffered more than the solid plate. Fig. 5 shows the form of the model at the place where it was most strained. It will be seen that this is very nearly circular, and should be compared with Fig. 6, which shows the form of Model No. 3, in which the joint and the plate near the point show signs of much greater distress than the rest of the plate. Seeing that the joint has only 55 per cent. of the strength of the plate against circumferential tension, this behaviour suggests the idea that plate and joint were not bulged by circumferential tension, but by a radial strain acting normally to the circumference. The most striking result is the fact that the form finally assumed was rather hollow in the centre. Uniform circumferential tension would, one would expect, produce a straight line, or one rather arched like that of Fig. 3, as the effect of ends would gradually diminish. Even a strain normal to the circumference which bulged up the points A and B (see Fig. 1) would, if acting alone, also lift up the line between A and B and keep it parallel. The form exhibited here seems then to indicate a distribution of strain in the shell in which the strain increases as the distance from the centre increases.

The question at once arises—Is this behaviour singular or in accordance with general law? The writer has not been able to find much evidence bearing directly on this point, but on looking through tables of boiler explosions, it will be noted that a large proportion have given way at the end seams. The experiments made last year by Mr. Scott, at Greenock, afford the most beautiful illustration of this curious phemomenon. It will be noticed that the short cylinder, No. 3, has hogged, while the longer ones, No. 1 and No. 2, have sagged at the centre. Now, if we look at Fig. 7, which is laid down from the dimensions given by Mr. Scott, and shows the form assumed by his experimental boiler at a pressure of 580lb., you will see that each of the short cylinders between the seams have hogged, but that the cylinder, as a whole, is much less stretched at the centre than at the ends. This form, strange as it may appear, is therefore not exceptional; it reappears in Model No. 2, but not in No. 3. No. 3 was the second model tested. Judging from its behaviour under pressures obtained by the hand pump it appeared to be decidedly weaker than No. 1; still, it stood 10 per cent. more than the ultimate strength of joint without serious damage. When connected to accumulator the pressure was raised very quickly. So far as the eye could detect the form of the model remained unaltered till near the point of rupture, the bulging of the shell and the bursting of the joint being nearly simultaneous, as far as he could judge. In this case the joint and the plate near the joint were evidently more strained than the rest of the plate. The radius at the joint was about 14¾in., and if it were true that the strain on the joint was radius by pressure, then this joint must have ruptured at a strain about 77 per cent. greater than its calculated strength. Model No. 2 appeared to be intermediate in strength between No. 1 and No. 3. It showed that the form assumed by No. 1 was not the result of accident, but of some general law. The results, being intermediate between 1 and 3, serve as a general confirmation of both.

The writer thinks he has now brought forward sufficient evidence to prove that the strength of cylindrical boilers is still an unsolved problem. And he repeats, what he has formerly stated before this Institution, that a true solution of the problem will apply equally to boiler shells subject to internal and to flues subject to external pressure. The generally accepted theory which treats boiler shells as endless rings cannot be right, and is not even an approximation to the truth in these experiments. The theory proposed by the author last year cannot be right, or No. 3 model would have stood nearly twice the pressure of No. 1, and Nos. 1 and 2 would not have yielded near the end joint, but at these joints. Neither of these theories can therefore be true, they both contain an element of truth and an element of error. The first theory appears to be nearly right in making the strength

of boilers depend on a ratio between diameter and thickness. The second theory, which assumes that the strain on the ends is not a small factor to be neglected, is confirmed by the evidence of straining near the ends. If these ends had been closed by a relatively weak tube plate full of holes instead of by these strong plates, it is the author's opinion that the weak tube plates would have yielded before the plate bulged, and he cannot believe that the original straight lines of these cylinders can have altered to either of the forms, shown in Figs. 1 and 2, or Fig. 3, without being stretched longitudinally; or that they could stretch longitudinally without overcoming a great resistance, which should be added to the resistance of plate to circumferential stretching. If then the errors could be eliminated, and the truth contained in these two theories combined, a true theory might be evolved from the process. The writer does not think this question can be settled by mathematics, but a few experiments made in a systematic manner would probably show, quite near enough for all practical work, what pressure can safely be used in any given boiler.

It is the writer's opinion that the experiments already made are sufficient to justify some alteration in our practice. All the models referred to stood a pressure of more than 540lb. with the small hand test pump. It cannot be far wrong to assume that this pressure had not strained them beyond their elastic limit. It would, therefore, be perfectly safe to make the test pressure for these two-thirds of 540lb. = 360lb., and the working pressure one-half of that, say 180lb. According to current practice the working pressure is only 80lb., and if 180lb. is quite safe, then in this case our rules are wrong to the extent of 125 per cent. If, as he believes, all those models yielded by bulging the solid plate and not by tearing the joint, then it follows that they would not have been stronger if the joints had been, as in boiler work they generally are, over 80 per cent. of the strength of the solid plate instead of only 55 per cent. With a joint of over 80 per cent. the working pressure would be about 120lb. according to present practice; if 180lb. is a safe pressure, then in such a case the error in the present rules is 50 per cent. The working pressure of these models, if calculated by the current rules, only substituting the strength of solid plate for that of joint, is about 150lb. This is still below the working pressure deduced from experiment, and, he believes, that it would now be quite safe to take the strength of solid plate as our basis instead of the joint, to keep other constants unaltered, and arrange our riveting with a view to tightness and caulking, without any regard to percentage of strength, provided that percentage was not reduced below 55. This would mean that with the same thickness of shell plates, the pressure might be increased 25 per cent., or that the same pressure might be carried with the thickness of shell plates reduced 20 per cent. This he considers a result of some importance, and future experiments may show that still further reductions might be safely made.

From a practical point of view there can be no question that, with the large boilers and high pressures now general, any reduction in thickness of shell plates which does not involve a reduction in the factor of safety is a benefit. If an inch plate is enough for strength, then, for many practical reasons, that plate is better than a plate $1\frac{1}{4}$in. thick. This, of course, does not apply to all sizes and pressures. No one would think of using $\frac{7}{8}$in. plate for a steam dome, for instance; a much thicker plate would be used for other reasons, entirely apart from the question of strength. Still, it is well to know what are the requirements of strength. Although they are by no means the only requirements which affect our designs, they always form a factor in the case about which it is better to know the truth than to be contented with an error. He regrets that he is not in a position to make a more exhaustive set of experiments, for he believes that there is a rich vein of discovery in this line. These experiments seem to prove that our present rules may be wrong to an extent anything between 50 and 125 per cent. It also seems to him that our rules as to boiler flues are very absurd. It is not possible

that their strength can vary inversely as their length; it is quite impossible that it can vary as the square of their thickness.

Before concluding, he wishes to record his thanks to Mr. Alexander Taylor for sharing the expense of these experiments; and to Messrs. Nichol, Sanders, and Walliker, for making and recording the measurements given in these tables; to Mr. Burrell for the tests of plates and joints. He has also to thank his employers, Messrs. the Tyne Boiler Works Company, Limited, for the use of their plant and machinery free of charge.

(To be continued.)

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 10th March, 1891.

Iron.—The state of the iron market last week, as regards the number of transactions, showed marked signs of improvement. At the same time prices remained low. Best bars were at 124s. 6d., joists 125s., and plates 156s. the ton; castings and old rails were quoted at the prices of the previous week. The prospect of an amelioration in the state of affairs continues to be good, and doubtless a change for the better will take place in the course of the next few weeks, as most of the Paris workshops have as many orders on hand as they can execute. The only drawbacks are that some of the contracts have been taken at a very low estimate for the material, which will necessitate the most advantageous terms possible being made with the producers. Moreover, steel is taking the place of iron in bridgework and other structures, thus causing transactions to be made on some other market than that of Paris. The Minister of War is about to solicit tenders for constructions at Varenne (Seine-et-Marne) to the extent of 1,000,000fr. The Société Cail have a large contract for sheds for the Roumanian Government, but most of the iron used therein will be brought into France from abroad. In the provinces business seems to be steadily improving. The shipbuilding yards at Nantes (the Chantiers de la Loire) are fully occupied, having amongst other orders on hand a despatch boat for the brother of the Czar of Russia, and a large iron sailing vessel. The Compagnie Transatlantique has been transformed into a limited company, with a capital of 8,000,000fr. The new company proposes to extend the works and to occupy itself with the construction of guns, locomotives, and engineering work in general, as well as shipbuilding. In the Ardennes the manufacturers of iron work for railways, the founders, and bolt makers are all fully occupied; also in the Haute-Marne district the steel wire trade is well employed, but in this, as elsewhere, a further improvement in the situation depends more on the price of fuel becoming lower than on the market prices of iron being raised.

Coal.—The coal market continues very firm. The deficit caused in stocks by the late cold weather is not yet made good. It is reported that one or two mining companies have engaged more than three-quarters of their output in advance for the year 1891.

Copper, Tin, Lead, and Zinc.—Best Chilian copper in bars was quoted at £58 5s. per ton, ordinary Chilian copper at £56 5s., and "best selected" at £60 7s. per ton. There has been a slight fall in the prices of both Billiton and Detroit tin during the past week. The following were the quotations at the end of last week:—Banca, £98 10s.; Billiton, £96 10s.; and Detroit, £95 10s. the ton. The lead market was, if anything, rather firmer, with unchanged prices. Zinc has increased in value, quotations being from 4s. to 8s. per ton in excess of the prices of the previous week.

Electrical Tramway.—The Municipal Council of Lyons have granted the concession for a line of electrical tramways between the Dombes and Perrache railway stations in that town to the Compagnie Lyonnaise des Tramways et Chemins de Fer.

A New War Vessel.—A new ironclad ram of the "Lazare-Carnot" type is about to be ordered. She is to be built of steel, and will measure 355ft. 9in. between perpendiculars, and 367ft. 4in. over all. She will be provided with three screw propellers, one of which will be placed at the stem, so as to assist in manœuvring. The armament is to consist of two 30-centimetre bow and stern chasers in closed turrets, two pieces of 27 centimetres in the waist, and four turrets with coupled guns of 14 centimetres; also a large number of Hotchkiss fast-firing guns and four torpedo tubes.

BERLIN, 9th March, 1891.

The Berlin Chamber of Commerce.—The Chamber of Commerce of Berlin has decided to found an institution which shall have for its object the providing of funds to send young merchants and engineers into foreign countries to improve their knowledge and promote German industrial interests. The various Chambers of Commerce are to be canvassed to support this plan. Bremen and Hamburg are of opinion that local societies would be better than a national institution.

Railway Passenger Fares.—The "Verein zur Beförderung des Gewerbefleisses" held its monthly meeting on the 2nd inst. One of the subjects of discussion was the proposals of the Government with respect to alterations in the passenger fares on the State Railways. Since the introduction of the "zone tariff" in Hungary, there has been a movement in Germany, which gradually increases in importance, to bring about a reduction of passenger fares, and a large association has been formed for the purpose of collecting statistics and influencing the authorities in this direction. The railways in Germany being, with few exceptions, either the property or under the management of the State, an alteration in existing systems is very difficult to attain, but it is evident that the Government see that some reform is necessary, as they have appointed a meeting of their chief railway officials for the 24th inst. The Government propose to reduce the fares of the first, second, and third class by about one farthing per mile, and to withdraw all reductions on return tickets and circular tours, and to abolish the "fourth class." The fourth class is simply a luggage van provided with small windows, and is largely made use of by peasants. These persons will be compelled to travel in the third class, and the proposed alterations will thus on the whole mean an increase rather than a reduction in the fares.

VIENNA, 9th March, 1891.

The Iron Market.—During the past fortnight prices have somewhat risen in the iron market, and the increase of prices was maintained at the end of last week. Now that the weather has become much warmer activity in the building trade has been increased, and the sorts of iron and steel used in building operations have been much inquired for. On the other hand, iron sheets, especially galvanised sheets, have suffered a considerable reduction, and the syndicate has lowered the prices by 15fl. per ton. By far the greater portion of the iron produced here is used by the railway companies. The companies feel the necessity of adding to their rolling stock in order to cope with the continually increasing traffic, and many new railways are being constructed. As regards the supply of rolling stock, the Austrian-Hungarian State Railway Company has recently ordered in Vienna six locomotives with tenders. In Hungary during the past year 500 kilometres of new lines have been completed, and the same length of lines is at present under construction. In Austria 150 kilometres of new lines have been opened for public use, and nearly 500 kilometres of lines are now being constructed. It has been calculated that on an average 2,750 men would complete 1 kilometre of line per day. The machine works and iron foundry company of Messrs. Ganz, in Budapest, held their general meeting the week before last. The yearly balance sheet showed the net earning to be 859,943fl. The total receipts of the five works of the company amounted to 12,000,000fl. The company will pay a dividend of 75fl., which is at the rate of about 20 per cent.

Electrical Engineering.—The formation of the General Austrian Electricity Company afforded good evidence of the confidence of capitalists in this branch of industry. 17,820 shares were placed on the market, and more than twenty times as many were subscribed for. The shares have a nominal value of 200fl., and were issued at 230fl. without any fluctuation. When the International Electricity Company was founded two years ago, its shares with a nominal value of 200fl., were subscribed for some hundred times over, and were issued at 240fl., the present quotation being 260fl. The latter company was founded by Messrs. Ganz & Co. and by the Union Bank, and although Messrs. Siemens & Halske and the Anglo-Austrian Bank, who are the founders of the General Austrian Electricity Company, deserve quite as much confidence from the public, the last issue of electrical shares shows that they have not obtained it.

Mercury Mines in Carniola.—During the past year 1,220 persons were employed in the mercury mines in Carniola, and the output of mercury amounted to 73,395 tons, of which the value was 850,000fl. Of the total amount, 92·6 per cent. was produced by the State mines in Idria, and the remainder at the St. Anna mines. Of metallic mercury there was an output of 528 tons in Idria. The average price of mercury per ton was 2,700fl.

BRUSSELS, 10th March, 1891.

The Iron Market.—There is a complete want of activity in the iron market. There are some large orders, but they are not sufficient to keep all the works fully employed. The supply of orders has slackened, and the closing of rolling mills and the blowing down of blast furnaces is already talked of. There is, however, an order for 200 waggons for the Government of the Netherlands, which has been given to the Dyle Company, and an order for weighing machines and signalling apparatus to Messrs. Divoire, of Malines. An order for staples and bolts has been given to the manufactories of Seneffe, and an important contract has been agreed upon at Salonica which will bring large orders on the market. Prices are as follow:—Iron No. 1, 125fr.; No. 2, 132·50fr.; No. 3, 140fr., delivered at Belgian railway stations; joists, 125fr.; angle iron, 132fr.; iron sheets No. 2, 150fr.; No. 3, 170fr.; No. 4, 240fr.; rails, 125fr.; pig iron (Luxembourg), 55fr. to 56fr.; red short iron, 48fr.; special quality, 58fr.

The Coal Market.—The condition of the market is uncertain. Prices are maintained, but it is thought probable that sellers will have to make reductions during the present month. Business is therefore restricted to present needs. There are rumours of strikes and of other events which would have an important effect on the market. The Belgian State Railways invite tenders for the supply of 11,000 tons of brown coal or patent fuel for the use of steamers at Ostend. The manufacture of coke still gives rise to much discussion. Its price has been maintained at 18fr. by the syndicate of owners of ovens. Statistics show that the importation of black coal from Germany into Belgium amounted to 64,490 tons during the month of January, as compared with 57,000 tons in the same month of last year. This increase has been caused through the high prices of Belgian coals. The import from England has fallen from 94,000 to 27,000 tons, and the import from France has diminished by 8,000 tons. The total reduction from 193,800 tons to 114,270 tons only serves to point out the scarcity of coal in Belgium during the first months of last year. The diminution is the less remarkable because English coal could not be imported during the closing of the Schelde. As regards exports, Germany has taken 6,100 tons during January, as against 11,500 tons in January of last year, and France 313,790 tons, as against 257,000 tons. The total export of coal from Belgium amounted to 358,829 tons, as against 300,900 tons. The import of double coke amounted to 9,927 tons, as against 4,270 tons the previous year, and the exports to 84,931 tons, as against 109,000 tons. The diminution in the export shows an important decrease in the output.

DÜSSELDORF, 10th March, 1891.

The Iron Market.—This market is quiet. The export business is suffering from the high rates of the raw material and the taxes caused by the social laws.

The Coal Market.—During the past week a circular has been issued by the Minister of Commerce, Mr. von Berlepsch, to the Boards of Trade, in which the administrators of the Westphalian coal pits were charged with improperly neglecting their old contracts in order to carry out new contracts at higher prices. As the real cause of recent irregularities in the supply of coal was the deficiency of waggons, and a want of precaution on the part of the State Railways, deep indignation prevails amongst the coal owners against the Government, which, in the first place, neglected its duties, and then made grave charges against coal owners. In order to answer these charges Mr. Fencke, of Essen, the President of the Westphalian Coal Owners' Association, who is also president of the directorate of Mr. Krupp's works, has called upon Mr. von Berlepsch in Berlin, and has obtained a withdrawal of those charges. A declaration has unanimously been made on the part both of the Westphalian Coal Owners' Association and of Mr. von Berlepsch, who is the chief surveyor of the royal mines in the Saar district, concerning the eight hours shift. It says that the shift below the surface is to last eight hours, not including the time for going up and down. During this week there will be a general meeting of all the German coal owners in Berlin for the same purpose. The eight hours shift was one of the demands of the miners, but the opinion prevails that they will not enter upon a general strike. If there should be a strike, it will be only a partial one. Notwithstanding this opinion, there are many who are collecting stores of coals for all contingencies, and not only the railway companies in the eastern provinces, but also important consumers in the western districts, have completed their stores. Amongst others, Mr. Fried. Krupp has just laid down a store of 5,000 tons of English coal in Duisburg. The coal market is very strong, and prices are rising. Smelting coke is at 160 marks, and blast furnace coke at 133 marks.

German Railway Waggon Manufactories.—These manufactories, of which there are twenty-two, are capable of turning out 3,680 passenger carriages and 24,200 goods waggons in one year.

Coal Mining.—Important extensions of the workings in the royal coal mines of the Saarbruck district have been already begun, and will be carried out during the years 1891 and 1892. Eight different sets of workings are to be provided with the newest machinery for increasing the output. In this district complete plants for draining five of the mines, chiefly at deep levels, are being laid down. Several new sets of ventilating machinery are being erected. Electric lighting is to be brought into operation in many cases in the higher levels.

Prussian Railways.—The sum of 145,337,500 marks is to be spent by the Prussian railways during the ensuing year, as follows:—

Construction of new railways...	36 008,000	marks
Widening of existing lines	26,305,500	,,
Enlargement of railway stations	29,427,000	,,
Rolling stock	53,800,000	
Total.....	145,537,500	marks.

AMSTERDAM, 9th March, 1891.

Coal in Sumatra.—The Dutch Indian Government has finally decided to work the extensive Ombilien coalfields in Sumatra itself, and not by granting a concession to private enterprise. It will also construct a railway from the coalfields to the nearest point on the coast for the transport of the output.

Steamers.—Messrs. Meyer & Co., steamship owners and agents for Holt's Company at Amsterdam, propose to commence a line of steamships with the Dutch East Indies, for which purpose they intend to enter into negotiations with the Government for the conveyance of mails, Indian produce, and Dutch Indian officials. In consequence of the attacks which the Ministry had to suffer in the Lower Chamber of the States-General regarding the shipbuilding contracts with the Royal Engine Factory in Amsterdam, the Government has decided to take away from the undertaking, now in liquidation, the contracts for the building of the monitor class ship "Reinier Claeszen," and of the turtle-back ironclad "Wilhelmina der Nederlanden." Both these warships are to be finished in the Government Shipbuilding Yard, and contracts will be made with other firms for the necessary boilers and engines.

Digitized by Google

FIRE AT ROZENDAAL.—The Java Sugar Factory, at Rozendaal, has been entirely destroyed by fire. The buildings, the machinery, and the sugar in course of treatment were all insured, chiefly with English fire insurance companies.

COMPETING STEAMSHIP COMPANIES IN THE ATLANTIC.—The competing steamship companies of Germany, Belgium, and Holland, whose vessels trade in the Atlantic, have come to an agreement whereby the cutting of rates will be stopped. The Hamburg and Bremen Companies have consequently raised their steerage rates by 10s., whilst the Red Star Line Company of Antwerp and the Netherland American Steamship Company of Rotterdam announce their intention of increasing those rates by 15s. a head.

VEGETAL BUTTER.—The Dutch Vegetal Butter Company at Amsterdam, having opened its factory, has now commenced to bring its vegetal butter to market. It is manufactured by the system of Dr. Schlinck, already applied at the only other factory in Heidelberg, and claims to be a pure and wholesome butter substitute, especially in cooking. It is what its name implies, a fatty substance which resembles butter, but contains no fat. It consists only of combinations of vegetal oils extracted from cocoanuts and other plants or fruits which contain oil. Vegetal butter wants an addition of salt when used, as, unlike margarine, no salt is added during manufacture. The retail price of this preparation is 8d. a pound.

STOCKHOLM, 7TH MARCH, 1891.

TRAMWAYS AT GOTHENBURG.—The profits of the Gothenburg Tramways Company, Limited, during the latter half of 1890 amounted to £6,315 12s. 6d., and the expenses to £5,198 17s. 11d. It is proposed to issue 6 per cent. debentures to the amount of £6,000. This sum will be partly used in buying more cars, so as to enable the company to carry on the large traffic anticipated during this summer on account of the show. It is proposed to pay a dividend of 4 per cent. per annum, which requires £1,050.

EXTENSION OF YSTAD HARBOUR.—It is proposed to extend the Ystad Harbour in order to meet the increasing demand for accommodation which the opening of the North Sea-Baltic Canal is likely to bring about. It is intended to be used also as a harbour of refuge.

NEW BEET SUGAR FACTORY.—The beet sugar industry in Sweden is continually being extended, and the erection of a new manufactory at Kristianstad is now being discussed. The project was favourably regarded at a large and influential meeting at Kristianstad, and a committee was formed for the purpose of advancing the plan. At a meeting, at Malmö, last week, of representatives of the various beet sugar manufactories in Skane, the price of beets was fixed at 1·85kr. for autumn and 2·10kr. for winter delivery per 100kgr., which is the same price as has been paid during the last few years. There appears to be some risk of over-production.

CHRISTIANIA, 7TH MARCH, 1891.

THE TRAMWAYS QUESTION.—The question of the extension of the Christiania tramways has been under consideration for a long time, and the adoption of electricity as a motive power has been suggested. The corporation has now appointed a committee to deal with the matter. Various concessions have been applied for during the last two or three years, but it has been found impossible to reconcile the conflicting interests of the applicants. The authorities are adverse to the introduction of steam trams, and seem to favour the accumulator system. Overhead wires are thought to entail various risks which should be avoided.

NEW RAILWAY MATERIAL.—The various Norwegian railways are to have a considerable amount of new material, both rolling stock and machine tools. It having been urged that home manufacturers ought to have the preference as to the delivery of locomotives, tenders were invited from some Norwegian makers, but these proved 15, 20, and 40 per cent. higher than offers from Scotland, and were not accepted.

NEW SEWING NEEDLE MANUFACTORY.—The firm of Messrs. Mustad & Sons, at Gjörik, are extending their works by the erection of a manufactory for sewing needles. Several English workmen have already arrived.

TELEGRAPH INSTRUMENTS OF NORWEGIAN MANUFACTURE.—The well-known firm of Messrs. A. I. Kragh has again delivered a number of Morse telegraph instruments for the State Telegraphs Department, which show good workmanship. In addition to these a similar order is being carried out for the State railways.

COPENHAGEN, 7TH MARCH, 1891.

THE COPENHAGEN FREE HARBOUR.—The proceedings in Parliament with reference to this important measure are now so far advanced that it is hoped the Bill will be eventually passed during the present session.

THE BURMEISTER AND WAIN SHIPBUILDING AND ENGINEERING COMPANY.—The balance-sheet of this company for last year shows that the gross profits were 801,690kr. for work done, and 50,461kr. profit on slip rent, 11,287kr. being carried forward from the previous year. The expenses were 398,948kr. The net profits amount to 464,613kr. The shareholders get 6½ per cent., or 130kr. per share, which amounts to 325,000kr. The buildings at Christianshavn are estimated to be worth 1,660,599kr., the shipbuilding establishment at Refshole 2,959,332kr., and the machinery 2,133,078kr. The share capital is 5,000,000kr.

MADRID, 9TH MARCH, 1891.

FRENCH AND SPANISH COINAGE.—Since the 1st inst., French gold coins of 20 and 10 francs and Spanish gold coins of 20 and 10 pesetas will circulate indifferently in both countries. This interchange of coinage will facilitate transactions between the two countries. If the metrical system had existed in England at the time when railways were first being developed in Spain it is probable that the bulk of the Spanish railways would have been in the hands of English capitalists and contractors.

BRANCH RAILWAY LINES.—A law to facilitate the construction of branch lines of narrow gauge railways will probably be passed by the Cortes at an early date. No less than from 6,000 to 7,000 miles of such railways are projected, and a fair rate of interest has been guaranteed.

INCIO IRON MINES.—A report has been circulated in the daily press of Galicia that some iron ore mines have been discovered in the province of Orense. The ores are stated to be of the finest quality, and are said to amount to 66 millions of tons, which is a larger quantity than is supposed to remain in the Bilbao mines. No reliance on the truth of this report is entertained at present by engineers of repute in the province. The owner of the concession is said to have extensive commercial relations with England. As the affair is of doubtful success, it is likely that much consideration will be given to it before any definite action is taken. Many iron mines in Spain have shown ores of rich and excellent quality at the surface, whilst the ores at a small depth below the surface have turned out to be of inferior quality.

MAIL CONTRACT FOR THE CANARY ISLANDS.—A contract has been offered by the Government for the carriage of mails twice a month between Spain and the Canary Islands. The steamers are to be of 650 tons, and to have a minimum speed of twelve miles per hour. A subvention of £1,000 is to be granted for the whole voyage. The traffic, independent of the mails, is comparatively small and irregular, but may possibly increase. No offer having been made at first, tenders have been again invited.

TENDERS FOR A NEW CRUISER.—The Spanish Government invites tenders for a new cruiser of 9,000 tons. The conditions of tender have been so modified on this occasion that foreign shipbuilders will be able to compete. Spanish tenders are, however, to be compared with foreign ones as if they were 12 per cent. lower than the sum actually stated, and this clause is certainly adverse to foreign tenders. It seems likely that the "Astilleros del Nervion" Company will get the order, and the difference of 12 per cent. should make the contract a profitable one. Sir Charles Palmer was for some time connected with this company, but it was reported lately that he had retired from it.

ROME, 9TH MARCH, 1891.

THE FOREIGN TRADE OF ITALY IN 1890.—The Government returns show that the imports and exports during last year compare unfavourably with those of 1889, as may be seen from the following figures:—

	1890.		1889.		Difference.
Imports ...	£52,663,443	...	£55,646,169	...	£2,982,736
Exports ...	35,030,426	...	38,025,830	...	2,995,404

It is to be noted that there has been an increase in the importation of raw cotton, and a decrease in the importations of cotton yarns and textiles, which shows that this branch of the Italian industries is steadily advancing. The importation of ores, metals, and manufactured articles in 1890 amounted to £6,736,500, and in 1889 to £7,792,227. This difference also shows the progress made in this branch of industry during recent years. There is a decrease in the importation of pig iron, a large quantity being now manufactured in the country. The same is to be said about raw iron and steel. There has also been a large decrease in the importation of locomotives, weaving machinery, and railway waggons. This decrease is due to a decrease in the demand, as well as to the increased capacity of the Italian engineering works. The exports for the same materials show an increase of £533,000, which is mainly due to iron ores, lead and copper ores, iron plates, copper ingots, bars, and sheets, mercury, and guns.

MARINE ENGINEERING.—Messrs. Ancaldo & Co., of Sampierdorno, have fitted three large steamers of the Navigazione Generale Italiana with new triple-expansion engines, of 5,000 indicated horse-power, with a boiler pressure of 110lb. per square inch. These engines are of the usual marine type, with three inverted vertical cylinders, the diameters of which are 0·94m. for high pressure, 1·55m. for medium pressure, and 2·50m. for low pressure. The stroke of the pistons is 1·52m. The steam is generated by four large double-fronted boilers, each of which has six furnaces. The steamers with the new engines have been recently tried, and have been found very satisfactory, giving 74 to 75 revolutions of the propeller, with 6,000 indicated horse-power, and at a speed of 11½ miles per hour.

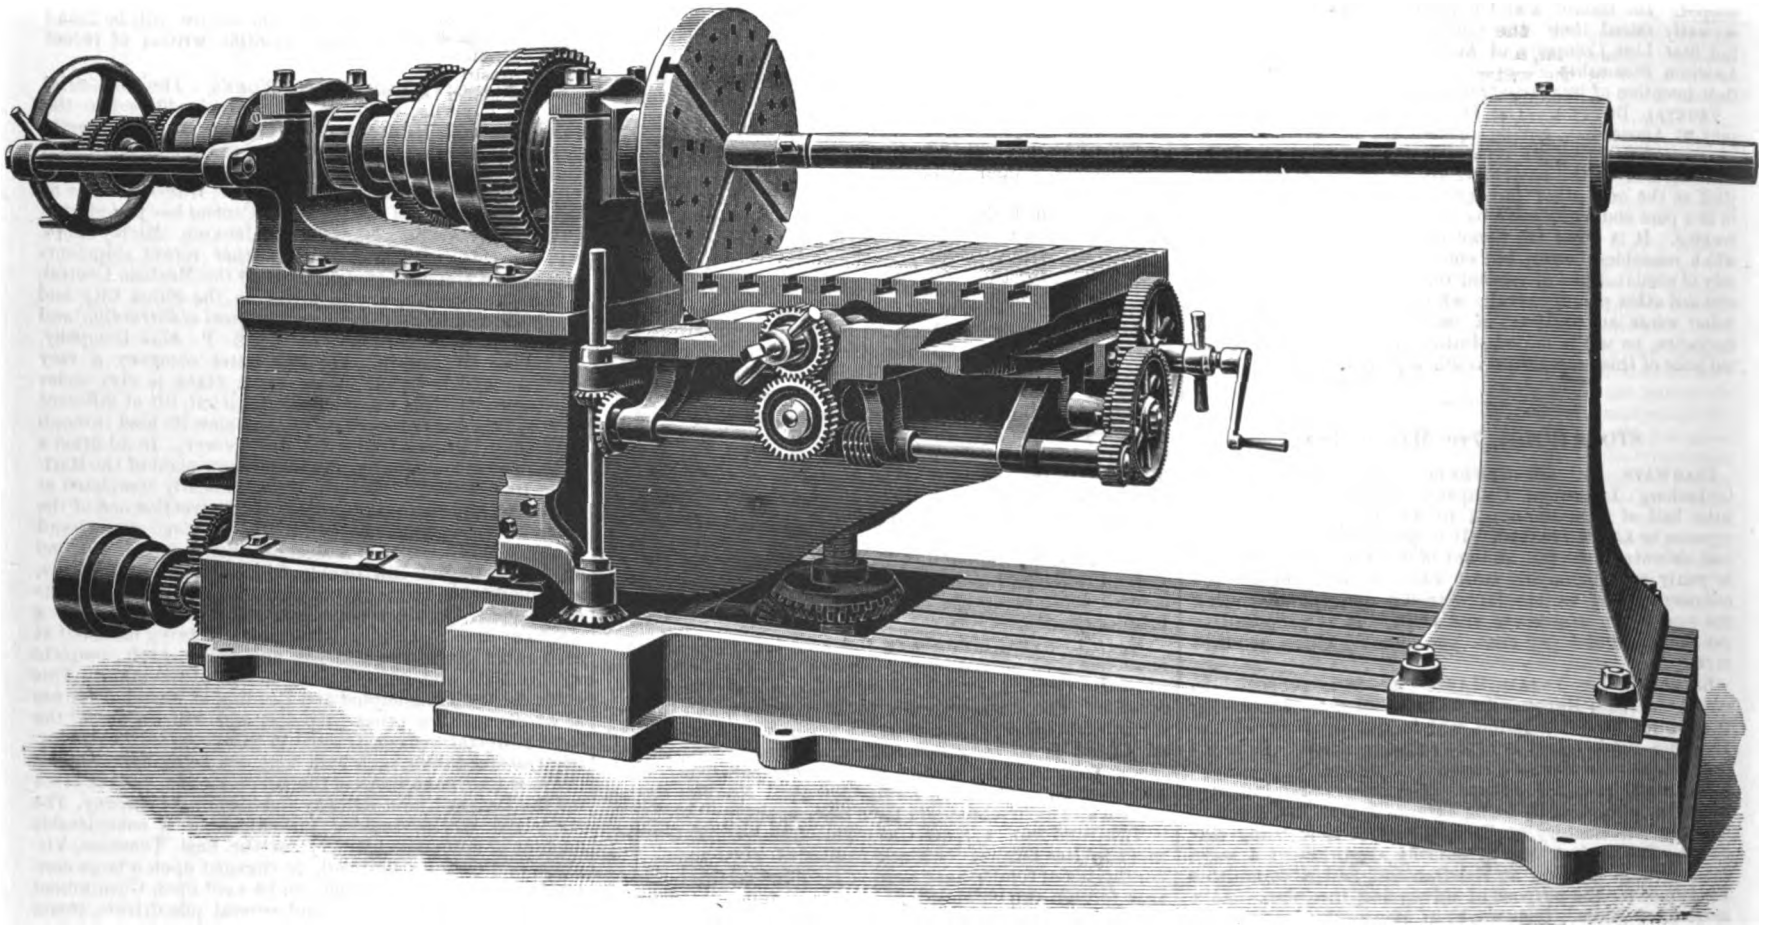
NEW YORK, 28TH FEBRUARY, 1891.

THE LATE MR. JOHN WILEY.—Mr. John Wiley, of the great publishing house of John Wiley & Sons, of New York, died at East Orange, N.J., on the 21st ult. Mr. Wiley was born in Flatbush, L.I., in 1808. At the age of seventeen he went into business with his father, a publisher in New York. Subsequently the firm became Wiley & Putnam, the latter being George Haven Putnam, then John Wiley, and, later, John Wiley & Sons. The house is widely known in the line of scientific publishing. On its list will be found the names of many eminent scientific writers of recent years.

THE BAY CITY INDUSTRIAL WORKS.—The Industrial Works of Bay City, Michigan, has recently shipped to the Union Pacific a steel car mounting two 15-ton capacity very complete cranes, which will be used at Salt Lake City, Utah, in wrecking and construction work. The Lehigh Valley is erecting one of its 20-ton steel transfer cranes at Jersey City, N.J., and the Michigan Central has just started a powerful travelling crane at the Jackson (Mich.) shops, built by this company. Among other recent shipments have been a standard steam shovel to the Mexican Central, at Tampico, Mexico, a pile driver to the Sioux City and Northern, and two steam jib cranes, steel construction, and of 10 and 25 tons capacity, to the E. P. Allis Company, Milwaukee, Wisconsin. For this latter company a very powerful and complete steam track crane is also under construction. This crane will propel itself, lift at different speeds, vary the radius of its jib, and slew its load through a complete circle, all with its own power. In addition a 10-ton power travelling crane for the new plant of the Marinette Iron Works, at Duluth, Minn., is nearly completed at the shops, and there is in process of construction one of the portable rail-sawing outfits for the Chicago and Grand Trunk. This consists of a steel car, boiler, and high-speed engine, cutting-off saw, double drill, hydraulic straightener, and the machinery for properly handling the rail in all of its movements. Another ponderous piece of machinery is a steel car some 48ft. long, upon which is being mounted at each end a 20-ton steam crane and boiler, each complete within itself and entirely independent of the other. This outfit for the Philadelphia and Reading is intended for use at wrecks and for other purposes, and will be one of the most powerful yet constructed in this country. Two electric transfer tables, each 70ft. long, are being built, one for the new Cheyenne shops of the Union Pacific, and the other for the Denver Union Railway and Terminal Company. The Industrial Works, besides just finishing a considerable amount of special machinery for the East Tennesse, Virginia, and Georgia Railroad, is engaged upon a large contract for dredging machinery, to be used upon Government work on the Great Lakes, and several pile drivers, steam shovels, and other tools.

PHILADELPHIA, 27TH FEBRUARY, 1891.

PETROLEUM EXPORTS.—The petroleum stills of the Philadelphia refineries at the beginning of 1890 had a capacity of about 43,000 barrels, and by the transfer to Point Breeze of the stills of the Chester Oil Refinery and the Globe Refinery, and by the regular increase in capacity, this has been increased about 20,000 barrels during the last year. The plant necessary for the shipment of petroleum has also been proportionally increased. The Philadelphia pipe line of the National Trust Company, which has a daily capacity of 9,000 barrels, is being taxed to its utmost, and the new Southern line, which has now been running a week, is sending in 1,500 barrels a day. The total storage capacity has been greatly increased during the year, and now exceeds 1,000,000 barrels. The rapid improvement of the facilities for doing business here promises to secure to Philadelphia a large share of the export petroleum trade of the country.



THE ILLINOIS STEEL COMPANY.—The business of the Illinois Steel Company, which recently increased its capital stock from $25,000,000 to $50,000,000, during the last year turned out 720,000 tons of pig iron, 36,000 tons spiegel, 733,000 tons of ingots, 509,000 tons of rails, 80,000 tons of billets, 54,500 tons of rods, and 70,000 tons of beams, angles, and merchant steel and iron. The receipts of raw material were 3,642,660 tons, of which about 20 per cent. was received by water, and the balance by rail. The company shipped 928,769 tons of finished product by rail, using 209,421 railroad cars for the year's shipments. The wages paid out during the year aggregated $6,863,416 to 9,648 employés.

PENNSYLVANIA RAILROAD.—The trouble between the men and officials of the Pennsylvania road are still unsettled, and every attempt is being made to have matters arranged amicably. The officials of the road insist, however, that the condition of the company's business will not allow an advance in wages, and the men seem equally determined that their demands shall be met. The leading members of all the societies among the employés have been assembling in Pittsburgh for several days, and a meeting of Council of the Federated Order of Railway Trainmen, which will be held in a few days, will probably decide whether there shall be a general strike or not. On the Western lines about 90 per cent. of all the men are members of the various organisations, while on the Eastern lines there are about 75 per cent. A strike will only be ordered as a last resort, and even then the company will receive four days' notice of the intended action.

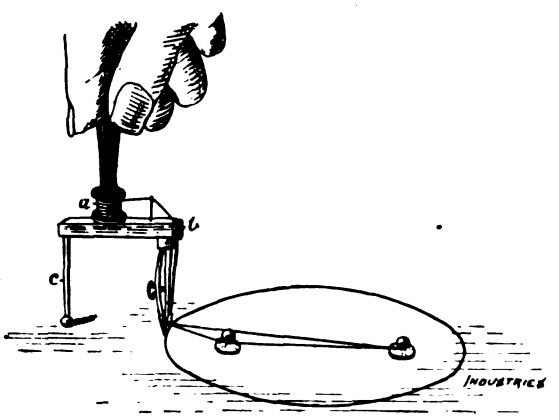
IMPROVED HORIZONTAL BORING AND CHUCK LATHE.

CONSTRUCTED BY THE NORTHERN ENGINEERING COMPANY, LIMITED, HALIFAX.

GENERAL VIEW.

BORING AND CHUCK LATHE.



THE lathe shown above is designed so that when large castings are to be operated upon they can be placed upon the foundation plate. The fast headstock is arranged with a steel spindle enclosed in a cast-iron barrel, and is fitted with self-acting feed motion, with three changes of speed, giving a traverse of 20in. to the boring bar, the outer end of which is supported by a strong standard. A quick withdraw motion is secured by a hand-wheel at the end of headstock. The machine will admit 18in. from centre of boring bar to top of table at its lowest position. The table has a transverse traverse of 24in. and a longitudinal traverse of 6in., or of 10in. when the face-plate is not in use, and this can be further increased by removing the wheels at the top of the knee-bracket. The vertical, transverse, and longitudinal motions of table are self-acting. The makers are the orthern Engineering Company, Limited, Halifax.

THE INSTITUTE OF MARINE ENGINEERS.

A MEETING of this Institute was held on the 3rd inst., and presided over by Mr. F. W. Wymer, when the discussion on the paper entitled "Application of Zinc in Boilers" was resumed. In opening the proceedings Mr. Green gave a supplement to his paper in reply to the discussion of the previous evening. In the discussion, zinc in contact with the boiler plates was advocated, not only in the water but in the steam spaces. It was mentioned that the use of kerosene and white zinc had been found a good preventative to corrosion when the steam spaces affected are painted with the mixture. It was remarked that the weight of zinc required in practice is about 4lb. to 5lb. per square foot of grate surface. Some references were made to the use of zinc in the form of electrogens and zynkara, and experiences were detailed showing where the results from the former had not proved so satisfactory as from the metallic contact with ordinary zinc plates. The author replied in detail to the various points raised in the discussion.

A SIMPLE ELLIPTOGRAPH.

THE accompanying illustration represents a neat and useful little instrument for drawing figures of elliptical form, which has been patented by Mr. C. E. Egner, of Asarum, Karlshaum, Sweden. The principle of the instrument is based upon the well-known method of drawing an ellipse by means of a pencil and a thread whose ends are fixed at its two foci. The instrument consists essentially of a pen or pencil fixed at right angles to a small horizontal bar, at the other end of which is similarly provided a leg *c* with a ball point which acts as a

rest. On the top of the bar a vertical handle, with a small reel *a* (containing a double thread) at its lower end, is mounted. This is revolved in order to lengthen or shorten the thread to suit the size of ellipse to be drawn. The thread passes down practically to the point of the pen or pencil, and is held secure by the small thumb-screw *b* (shown). The ball-headed pins are pressed into the paper at the foci of the required ellipse. The thread is placed around them, and the curve is then completed in the usual way. The instrument is provided with pen and pencil, legs and pins, and is neatly arranged in a small case. The combined set can be obtained from Mr. C. I. Lundstrom, 17, Fleminggt, Stockholm.

LEEDS ASSOCIATION OF ENGINEERS.

AT a meeting of this Association, held in the Chemical Lecture Theatre of the Yorkshire College on the 26th ult., Professor Smithells delivered a lecture on "Rust." He remarked that if they were to do anything on the subject of rust, they must begin by studying the conditions under which rust was formed, getting to know as much as possible about the phenomenon itself. The question was, Was it the chemist or engineer that was to tackle the problem? The answer in this case, as in so many others, was that the two must work together; they must combine theory and practice. His object would be mainly to take the chemist's attitude, and to explain to them the chemistry of rust, and to hint at one or two ways in which attempts had been made to obviate its formation. Rust, of course, was more or less a general phenomenon. It was not restricted to iron, but was most noticeable in the case of iron because iron was the most abundantly used metal, because the rust of iron formed rapidly, because it assumed a scaly character, because of its colour, and because of the fact that rust was a thing that appeared to grow in the case of iron, and it did not grow so rapidly, if at all, in the case of other metals. Most metals, of course, did rust. They knew they could not expose the bright surface of copper or zinc without the surface becoming dim. These metals might, therefore, be said to rust in their respective ways, but the rusting was very slight as compared with iron, which was the most susceptible to rust. Iron rust was found to consist of three elements—iron, oxygen, and hydrogen. That rust did contain water could be shown by the simplest experiments. That rusts were oxides they could easily prove, because they could produce rust by burning metals in oxygen alone, hence there could be no other element present, but the way that might appeal to them would be by getting the metal back again from the rust, and the oxygen as well. The lecturer demonstrated this by experiments with iron rust. The experiment he had done, he remarked, was a very suggestive one, because in getting the iron back from the rust in that particular operation he had done what had to be done so often in the process of soldering. They knew that before they could unite two pieces of metal by solder they must use a flux. The reason was that the two metals might be

Digitized by Google

covered with a thin film of rust, and the solder would not adhere to these two unclean surfaces. What was the cause of iron rust? They all knew that rusting was favoured by the presence of the air, and by the presence of moisture, but they wanted to know which of these two was the active agent, whether both were necessary, and whether anything else took part in the process. They wanted to know why rusting went on so rapidly and at different points, and how it was affected by the different composition and qualities of the metal, and by impurities in the metal, in the air, or in the water. Professor Smithells then showed some specimens of iron in jars, which he had been preparing for some time. One was a piece of iron in dry oxygen, and he explained that that would not cause the iron to rust. Next he showed a piece of iron which had been sealed up in water for some days, remarking that it was found that when they excluded air and other gases from the water no action took place, and a second conclusion was that water alone would not affect iron. The next question was—Would air and water together affect iron? That experiment had been tried, and it had been shown that, wherever action had taken place at all, the action had been exceedingly insignificant, and the question arose—What was it that was absent and that caused the rust? The one ingredient which was present in one of the jars, and was not present in the cases he had shown, was carbonic acid gas. Carbonic acid gas existed in the atmosphere to a small extent, and it was this gas in the air that was all-important in the operation of rusting. Pure air, pure water, pure carbonic acid would not act singly upon iron; pure water and pure air would not act together upon iron, carbonic acid and air would not act upon iron, but when they had carbonic acid, water, and air together, they got rust. It was carbonic acid that really set up the rust action, and when it was formed the carbonic acid was liberated and attacked the layers beneath. That was why rust had got the property of travelling inwards How could they prevent this action of rusting? There were many things which had been tried. They might paint the iron, and if they observed certain precautions they might have an effective method. One precaution was that the metal must be perfectly clean. A spot of rust embedded below a coat of paint would often break out of itself. Then there was the method of covering the iron with oils and tarry matters. There was also the process of galvanising iron; the process of enamelling, which was very useful for small articles, but the enamel was apt to chip off; and there was the Bower-Barff process, which was worked at Keighley, and which was an admirable process. Alluding to boilers, he said that by putting soda into them not only did they correct acidity of the water, but they introduced something which would absorb the carbonic acid gas, and prevent it acting in a rusting capacity.

SHIPBUILDING NOTES.

On the 7th inst. the s.s. "Blenheim," which has been built by Messrs. Wm. Gray & Co., Limited, for Messrs. Wilson & Corner, of Whitby, had her trial trip. She is 295ft. in length, 38ft. 10in. broad, and 22ft. 10in. deep, and takes Lloyd's highest class. The Central Marine Engine Works of Messrs. Wm. Gray & Co. have supplied the engines, which are of the triple-expansion type, having cylinders 22in., 35in., and 59in. diameter, with a stroke of 39in. There are two large steel boilers, working at a pressure of 160lb. per square inch. The performance of the ship and her machinery was highly satisfactory.

On the 9th inst. the s.s. "Acanthus" was launched by Messrs. Alexander Stephen & Sons, Linthouse. The steamer has been built to the order of Mr. J. B. Murray, Glasgow. The tonnage of the vessel is 3,000, and the dimensions are:—Length, 310ft.; breadth, 42ft.; and depth, 25½ft. The main framing is extra heavy, and the hull is divided by longitudinal intercostals. The holds are unobstructed by beams, and are thus suitable for bulky cargo. The engines are of triple-expansion type, with cylinders of 23in., 37in. and 59in. respectively.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, March 13th, at 7.30 p.m. Students' meeting. Paper to be read: "The Lanarkshire and Ayrshire Railways," by Mr. W. A. P. Tait.

Society of Arts.—Friday, March 13th, at 4.30 p.m. Lecture on "The Science of Colour," by Captain Abney, F.R.S.

Royal Institution.—Saturday, March 14th, at 3 p.m. Lecture V., on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

Manchester Association of Engineers.—Saturday, March 14th, at 7 p.m. Paper to be read: "The Construction of Self-adjusting Bearings," by Mr. E. G. Constantine.

NEXT WEEK.

Society of Chemical Industry.—Monday, March 16th, at 8 p.m. Papers to be read: "Observations Made in the Working of Vitriol Chambers," by Mr. W. Crowder; "The Chemistry of Whiskey and Allied Products," by Mr. A. H. Allen.

Society of Arts.—Monday, March 16th, at 8 p.m. Cantor Lecture II., on "Photographic Chemistry," by Professor R. Meldola, F.R.S. Tuesday, March 17th, at 8 p.m. Lecture on "Recent Development of Tasmanian Industries," by Sir Edward N. C. Braddon, K.C.M.G. Wednesday, March 18th, at 8 p.m. "Harbours, Natural and Artificial," by Mr. F. H. Cheesewright.

Institution of Civil Engineers.—Tuesday, March 17th, at 8 p.m. Adjourned discussion upon Mr. J. T. Harrison's paper "On the Subterranean Water in the Chalk Formation of the Upper Thames."

Owens College Union Engineering Society.—Tuesday, March 17th, at 7 p.m. Paper to be read: "The Blowing Room," by Mr. I. Goëtz.

Royal Victoria Hall.—Tuesday, March 17th. Paper on "Thunderstorms," by Mr. A. W. Clayden.

Royal Meteorological Society.—Wednesday, March 18th, at 7 p.m. Paper to be read: "A Contribution to the History of Rain Gauges," by Mr. G. J. Symons, F.R.S.

Newcastle-upon-Tyne Association of Students Inst.C.E.—Wednesday, March 18th, at 8 p.m. Paper to be read: "The Railway Bridge over the River Tyne at Wylam," by Mr. W. G. Laws, M.Inst.C.E.

Institution of Mechanical Engineers.—Thursday, March 19th, and Friday, March 20th, at 7.30 p.m. Papers to be read and discussed: "Fourth Report of the Research Committee on Friction: Experiments on the Friction of a Pivot Bearing"; "On Recent Trials of Rock Drills," by Mr. E. H. Carbutt and Mr. H. Davey.

Royal Institution.—Thursday, March 19th, at 3 p.m. Lecture on "Modern Chemistry in Relation to Sanitation," by Professor C. Meymott Tidy.

Chemical Society.—Thursday, March 19th, at 8 p.m. Papers to be read: "The Molecular Refraction and Dispersion of Various Substances," by Dr. J. H. Gladstone, F.R.S.; "Contributions to our Knowledge of the Aconite Alkaloids. Part I. The Crystalline Alkaloid of Aconitum Nepellus," by Professor Dunstan and Dr. W. H. Ince; "The Crystallographic Character of Aconitine from Aconitum Nepellus," by Mr. A. E. Sutton.

PRICES CURRENT, 11th March, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues inactive, with small business. Published statistics show a decrease in stocks during February of about 1,560 tons. Owing to the slack demand, values of raw copper are receding, Chili bars to-day being quoted £51 2s. 6d. to £51 7s. 6d. cash, with good trade reported. Manufactured steady at £65, "strong."

Tin: Without change, the fluctuations during the past week having been within very narrow limits.

Lead: Quiet; values unchanged.

Spelter keeps very firm, and is scarce.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Business has continued quiet since our last, and there is very little of interest to report. Sulphate of copper is in better request for shipment, and prices have advanced slightly. Green copperas is now more freely offered. Acetates of lime are steady, but little business doing. Borax is firm, and is expected to advance.

HOME INDUSTRIES.

LONDON, 12th March, 1891.

THE MONEY MARKET.—The slight stringency in the money market has quite worn off, and rates are again easy, and seem likely to become more so. The outward drain of gold has ceased for the time, and the Bank's stock is growing in strength. On the Stock Exchange dulness still prevails. There is no business to speak of, and in no quarter, except perhaps among silver securities, is there indication of improvement. Home railways are quiet, and Americans are drooping and neglected. Much attention has been concentrated on the Canadian railroads, owing to the recent elections in the Dominion, and the failure of the Opposition to oust the Government has told favourably on Canadian Pacifics. Grand Trunks have suffered severely through the company identifying itself with the United States party in Canada. Among foreign securities Argentines have been depressed, owing to the revival of financial troubles at Buenos Ayres, which has not been counterbalanced by the conclusion of the coupon-finding arrangements. Mining and miscellaneous shares have exhibited no striking feature.

THE GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company show that the receipts in February, 1891, were £20,800. The total receipts from January 1st to February 28th were £41,600, the receipts for the corresponding months of 1890 and 1891 being £39,400 and £42,000.

THE REGISTRATION OF BOILERS.—A Bill has been introduced into Parliament to ensure the periodical examination and registration of steam boilers throughout the United Kingdom by competent "lay inspectors." The owners of boilers are to be held responsible for the competency of the inspectors, whom they may select. The certificate, which is to be valid for a period not exceeding thirteen months, will state that the condition, construction, and fittings, as well as the setting, general equipment, and surroundings, of the boiler admit of its being worked at a certain pressure for a definite period. The lay inspectors' certificates are to be sent to the Board of Trade, who will issue licences to the owners. The Bill will not require any expenditure of public money, as the expenses connected with the examination and registration of boilers are to be paid for by the owners. Owners of boilers are to be liable to a fine of £1 per day for using boilers which are not licensed and numbered, and a fine of £5 per day may be exacted from owners after a failure to comply with regulations has been notified by the registrar.

THE IMPERIAL INSTITUTE.—On the 5th inst. a meeting of the Organising Committee of the Imperial Institute was held at Marlborough House. There were present—the Prince of Wales, K.G., President (in the chair), Lord Herschell (Chairman of the Organising Committee), Sir Lowthian Bell (Vice-Chairman), and a large number of members of the Committee. Sir Frederick Abel, organising secretary, and Sir Somers Vine, assistant secretary, were in attendance. The progress of the building operations having been duly reported, the draft scheme of constitution, prepared by a special sub-committee, together with regulations for the admission of Fellows to the privileges of the Institute when opened, were considered in detail, and finally approved and confirmed for submission to the Privy Council, as required by the charter of incorporation.

INTERNATIONAL CONGRESS OF HYGIENE.—The Seventh International Congress of Hygiene and Demography will be held in London from August 10th to the 17th. The subject to be discussed by the Congress is that of Section VI., "Architecture in Relation to Hygiene," and deals with (i.) "The Laying out and Extension of Towns; (ii.) "Buildings." All communications relative to this section should be addressed to Mr. E. Turner, 246, Regent Street, W., whilst letters relating to the general business of the Congress should be addressed to the Hon. Secretary-General, 20, Hanover Square, W.

THE EDUCATION CODE AND THE DECIMAL SYSTEM.—A deputation from the Decimal Association last June presented a memorial to the School Board for London, praying that the metric system should be taught in the Fifth Standard, and that decimal fractions should be taught in the Fourth Standard at latest. After due consideration the Board petitioned the Education Department to make the necessary provision in the new Code, and this was subsequently supported by thirty-seven other School Boards. On reference to the Code, it will be seen that the Education Department has inserted the provision desired, the following foot-note having been appended to Schedule I.:—"The scholars in Standards V., VI., and VII. should know the principle of the metric system, and be able to explain the advantages to be gained from uniformity in the method of forming multiples and sub-multiples of the unit. As a preparation for this it will be useful to give in Standard IV. elementary lessons on the notation of decimal fractions."

THE IRON AND STEEL INSTITUTE.—On the 11th inst. a committee of members of this Institute entertained Dr. Raymond, the Secretary of the American Institute of Mining Engineers, at dinner at the Grosvenor Club, New Bond Street, W. In connection with the trip of the Iron and Steel Institute to the United States last year, Dr. Raymond will be long and gratefully remembered on this side for his courtesy, and for the active part which he took in making that trip a great success.

MORLEY MEMORIAL COLLEGE FOR WORKING MEN AND WOMEN.—Scholarships have been offered to those students who pass the best examinations in astronomy, electricity, chemistry, descriptive geometry, and machine drawing in order to enable them to spend some time during the August vacation in attending the summer classes, which have been specially arranged at Oxford and Cambridge for University Extension students.

MANCHESTER, 12th March, 1891.

THE SHIP CANAL.—At a special meeting of the Manchester City Council the recommendations of the special committee appointed to inquire into the desirability of rendering aid to the Ship Canal Company was received. After some discussion, the Council unanimously agreed to the recommendations of the committee, and the Mayor and Sir J. J. Harwood left for London to forward the interests of the proposed Bill. There is a very unanimous feeling in the district with reference to this matter, and a demand for the formation of a public trust to acquire and manage the business is finding many supporters.

TECHNICAL SCHOOL.—A rather novel departure is being made in Oldham. The Mutual Cotton Class in that town, which consisted of an association of overlookers and managers who periodically met to discuss matters of trade interest, resolved a short time ago to start a movement in favour of technical training. They have accordingly taken rooms which they have fitted up, and in which a complete series of machines for spinning cotton have been erected. It is intended that the overlookers, who are by their occupation confined to one department, shall, under the guidance of their fellows in other departments, acquire a knowledge of the method of working the machines with which they are not so well acquainted. The mutual character of the undertaking is to be carefully preserved, and the discussion of practical points is to be continued as hitherto. Already this association, now styled the Oldham Technical School Classes, has done a great deal of useful work, and its value will be largely increased in the immediate future.

THE ENGINEERING TRADES.—There are several signs of a diminished amount of trade, but it is difficult to say whether it is only temporary or permanent. Most makers have plenty of work on hand to keep them going for some months, but in the meantime there is not so much new business coming in. The boiler-making and engine-building departments are fully occupied, and in machine tools the demand has not yet fallen away, orders for new tools having been given out recently. In textile machinery there is as yet a large amount of work being done, and in this branch there is not likely to be much slackness for some months. There is, however, a much worse tone among spinners than there was, and it is not likely that many new mills will be projected for some time to come. In most quarters there is a hopeful spirit shown, and both from home and abroad there are a few orders of considerable magnitude. Coppersmiths have not been so busy during the early months of this year as they were previously, and the weight of manufactured copper going into use is not very great at present. Among miscellaneous machines it may be mentioned that the Theisen condenser, which is made by the Union Engineering Company, is being utilised in one or two places where a supply of water is scarce.

THE LINEN AND JUTE TRADES.—This has been another quiet week, and the situation becomes positively discouraging. Everything seems to be against both manufacturers and shippers. The home demand is decidedly poor, and there is really no branch upon which sellers can rely. It is difficult to see how, under existing conditions, full employment can be afforded to so many looms as were running last year. The South American outlets for trade do not improve, but seem to become worse. The Canadian market is in a poor condition, and the dry goods trade of the Dominion has been adversely affected by the elections and by the fact that farmers are not making their usual purchases. For the United States there is a fair general trade in linens and unions. The Australian and Cape markets, however, are unsatisfactory, and if producers had to depend on these markets for the disposal of their cloth there would not be many looms running. Sales of jute fancy goods are maintained. The demand for articles of this description has for some time been a growing one, and Dundee has secured very good orders from this district, and will probably continue to do so. There is no change of importance in the linen thread trade, which keeps steady. Messrs. Ainsworth are making alterations in their agency here.

GLASGOW, 12th March, 1891.

SHIPBUILDING.—The Inman liner "City of Paris" has arrived at Glasgow for the purpose of having a new set of engines fitted by the builders, Messrs. J. & G. Thomson, Clydebank. At present the vessel lies at Yorkhill Wharf, where Messrs. Howden & Co. are completing the fitting of the boilers with their system of forced draught, the work having been begun at Liverpool while the "City of Paris" was lying there. The vessel steamed from Liverpool to Glasgow propelled by a single engine, the other having been destroyed by the accident which befell the ship last year.—Messrs. Caird & Co., Greenock, have contracted to build two steamers, of 4,500 tons each, for the Dutch Transatlantic Company, for whom the same builders have already built two steamers.—The Greenock Steamship Company are about to establish a line of steamers from Glasgow to Adelaide, Melbourne, Sydney, Newcastle, and Brisbane. Messrs. Caird & Co. are to build a new steamer for this line. The Greenock Steamship Company, Limited, has declared a dividend for the half-year of 5 per cent., with a bonus of 2½ per cent., making in all 12½ per cent. for the year.

SCOTTISH RAILWAYS.—The phenomenal fall in Scottish railway stock, which was due partly to the prospective loss in dividend and increase in working expenses caused by the strike, and partly to the likelihood of traffic returns being affected seriously by the falling off in general trade, has been, for the time at all events, checked. The fall in North British Ordinary and Preference Stocks has been most marked. North British Ordinary has lost £7 3s. 9d. during the course of the last account from the 23rd ult. to the 9th inst. North British Ordinary Preference has lost £8 6s. 3d., while Caledonian has lost £5 5s.; Preferred, £1 10s.; and Deferred, £3 10s. The combined stocks of the North British stood on 6th October, 1890, before the prospect of a strike assumed definite shape, at £137¾; on the 9th inst. they stood at £107½, a fall of about 30 per cent. of the par value. The slight check in the fall is due to the desire on the part of "bears" to cover their sales. Yet the North British Preference Stock has continued to fall. On the 10th inst. it stood at 65⅛. The dividend falls to be declared this afternoon.

CARRIAGE OF PETROLEUM.—The answer given by the Home Secretary to a question put in the House of Commons in reference to the transport and storage of petroleum seems to indicate a disposition on the part of the Government to prohibit the employment of wooden barrels for its storage and transport. The result of any such prohibition would entail the expenditure of a large amount of capital in iron drums, since at present the trade is carried on almost entirely by means of wooden barrels.

ENGINEERING.—Messrs. Kincaid & Co., Limited, have just completed the fourth year of their existence as a joint stock concern. Last year they closed their account with a debit balance of about £500, but this year they have recovered this loss, provided for various contingencies, and have declared a dividend of 10 per cent.

(From our own Correspondents.)

LIVERPOOL, 11th March, 1891.

THE TIMBER TRADE.—The trade during the past month has been very quiet, with no improvement in prices, the stocks being too heavy. There has been a fair consumption of yellow pine waney, but square has not been in demand; the stock of 541,000ft. is more than the trade at present requires. There is little or no inquiry for red pine, and the stock is ample. There is a large stock of New Brunswick and Nova Scotia deals, although the import has been small; prices have not improved in consequence. The stock of oak is heavy with no imports; the consumption is small and the prices unchanged. The arrivals of oak waggon planks have been large, but the deliveries have been larger. The stock is light. First-class planks of suitable scantling command good prices, with an upward tendency. The demand for United States and Quebec walnut has been steady, and the prices at the quays have ranged from 3s. 4d. to 4s. 6d. per cubic foot. There is not much demand for elm, only 3,000ft. going into consumption as compared with 10,000ft. the same month last year. The stock of ash is heavy and the deliveries small. The auction sales of mahogany and other furniture woods were well attended, and satisfactory prices were realised.

TECHNICAL EDUCATION.—In connection with this subject Professor Hele Shaw, M.Inst.C.E., recently read a paper on "The Education of an Engineer" before the Liverpool Engineering Society. In the course of his paper the author stated that a committee of the council of the Society had been appointed to watch the disposal of such funds as might be devoted by the Liverpool City Council to engineering education under the Technical Instruction Act

LEEDS, 11th March, 1891.

THE IRON AND STEEL TRADES.—Business generally is still very quiet, but ironfounders are well employed, as a large amount of construction work is going on. The forges, as a rule, are not running full time, and difficulty is experienced in obtaining orders to fill the place of old contracts which were taken at better prices than at present prevail. As regards the steel trade business is perhaps more brisk than in the iron industry, though prices are kept down, owing to competition from the Continent, especially in girders. For two or three years engineers and machine makers have been kept very busy, but the depression is now making itself felt, and the new orders are not sufficient to replace present deliveries. In regard to the locomotive trade, however, Messrs. Kitson have lately received an order for forty engines from the Midland Railway Company. There is a feeling in some quarters that relief ought to be given by the coal owners, as the prices of fuel are little less than when iron was nearly 20s. a ton higher. The Leeds Forge Company will pay a dividend for the year 1890 at the rate of 8 per cent. on the ordinary and 7 per cent. on the preference shares.

THE COAL TRADE.—There seems to be less briskness in the coal trade, and at some pits stocks are accumulating. Prices remain unchanged.

Digitized by Google

SHEFFIELD, 11th March, 1891.

Iron and Steel.—The prices of manufactured iron and steel show a decided tendency to decline, and if the cost of fuel is reduced the prices of iron and steel will soon follow. The chief interest of this week has been in the receipt of further orders for rolling stock from the home railways. The Manchester, Sheffield, and Lincolnshire Company have placed with Messrs. Ashbury, of Manchester, an order for 660 waggons, of various types, including open and covered goods waggons, brake vans, and timber trucks. This order is an addition to the 500 heavy waggons now being built by Messrs. Ashbury for the company. The tyres, axles, and springs will be made in this district, and the ironwork by Messrs. Ashbury, who have special plant for this class of work. The Glasgow and South-Western Company have ordered 350 waggons from Messrs. Brown & Marshall. Most of the springs and tyres will be made by Messrs. Cammell.

Engineering Trades.—The engineering trades are well employed generally, but it is mainly of a special class. Messrs. Hawksley, Wild, & Co., of the Brightside Works, are turning out some fine boilers. Messrs. Ward & Rhodehouse are making a specialty of telescopic lifts, which are made from weldless steel tubes in a most satisfactory manner. File cutting machines are being exported largely to France and Germany.

Fuel.—There is little change in the market, and prices are high. Local collieries are fully employed. The Sheffield Gas Company have agreed to pay their usual dividend of 10 per cent. The company sell 15 to 16 candle-power gas at 2s. 4d. per thousand. A naphthalene deposit in the service pipes is causing much trouble. The capital account now stands at £654,396 6s. 9d. Last year the company sold 78,000 tons of coke. The staple trades of the town are fairly well employed, especially in work of the best class. Files are not selling well, but the agricultural implement trade is improving. The building trades are in a poor condition owing to the continuance of severe weather.

NORTH STAFFORDSHIRE, 11th March, 1891.

The Iron Trade.—A general curtailment of output is becoming an absolute necessity, and is being extensively carried out, as, owing to the enhanced cost of raw materials, and the disadvantage at which this district is placed in consequence of its landlocked position, present prices of finished material and the crude metal involve manufacturers in a heavy loss. Pig iron is being sold at 42s. 6d. per ton for forge purposes, and common bars are being offered at £6 per ton delivered at Liverpool or port of equal facility.

Trent and Mersey Canal.—On the assurance of the general manager of the North Staffordshire Railway Company that it was proposed to widen this canal throughout the route from Stoke-on-Trent to its junction with the Manchester Ship Canal, the opposition of the local Chamber of Commerce to the railway company's scheme, which was regarded as inadequate, has been withdrawn.

BIRMINGHAM, 11th March, 1891.

General.—There is practically no improvement in the state of trade in this district. New orders in most industries are scarce, though many works are still fairly well employed on old contracts. The bedstead trade is, perhaps, a little brisker, and safe makers have a good many orders in hand. Tube works are busy, and some of the leading makers have good orders for gas cylinders for railway carriages. Cart and carriage axle makers report a fair demand. Makers of light brass castings are not well employed. Coal and coke continue high in price, and ironmasters find it difficult to make profits; notwithstanding this, the prices of manufactured iron seem to be declining a little. Bridge and girder builders are getting a considerable quantity of their material from Cleveland, as the low prices in that district enable them at the present time to bear the cost of carriage and still buy cheaper than from the local works.

Limited Companies.—Messrs. Muntz's Metal Company pay on the ordinary shares a dividend of 7½ per cent. for the half-year ending December 31st last, making 10 per cent. for the year; also a bonus of 5 per cent. on ordinary and a dividend of 5 per cent. on preference shares for the year. Messrs. Allday's & Onion's Pneumatic Engineering Company's annual meeting was held on the 9th inst., and the report of the directors was adopted. The dividend is 10 per cent. on ordinary shares and 5 per cent. on preference, £7,000 being placed to a reserve fund.

LEICESTER, 11th March, 1891.

Wool Spinning and Yarn Trades.—There is little variation in the condition of the local wool market. Prices remain very firm indeed at late rates. Though there is a lack of animation in the market, there is a fairly large consumption, but users buy only for present wants. Bristol wool fair, this week, is regarded as fixing the price of English wool, and many users are postponing their operations till this is over. Spinners are only moderately busy, and the output is rather restricted. There is plenty of new business offered, but prices are so unremunerative that spinners refuse to enter into contracts unless at an advance which is seldom obtainable.

Hosiery Trade.—There is a slow but steady improvement in this industry. For the time of the year there is a fairly good amount of business, and some good contracts have been taken both for home trade and for export. Fancy hosiers are becoming busier. As stocks are low, and buyers are disposed to operate, there is a very cheerful prospect of good trade in the coming season.

SWANSEA, 11th March, 1891.

Tinplates.—The Manufacturers' Association has discussed a proposal for combination in view of the new American tariff. The idea, which meets with general favour, is to reduce as much as possible the stocks in the United States, so that the industry in South Wales may not suffer too sudden and severe a relapse when the tariff comes into operation. Since, however, the falling off in American orders is regarded as an inevitable consequence in the not far distant future, the associated masters have decided to send out men to Ceylon, Japan, and China to teach the natives how to pack tea in tinplate boxes. This endeavour if successful must give a great impulse to the tinplate trade.—At a recent sale, after a keen competition, the Midland Works were sold to Mr. Thomas Bowen, of the Morriston Tinplate Company, at the reserve price of £10,000.—It is interesting to note that the value of tinplates and sheets exported during the first two months of the present year amounts to £1,180,962, as compared with £875,701 during the same period last year. The weights of the said exports, are for the two periods named, 72,322 cwt. and 56,734 cwt. respectively.

CARDIFF, 11th March, 1891.

Iron and Steel.—There is no improvement in the manufactured iron and steel trades, and the outlook is worse than before. Steel bars for tinplate making, which have been the principal article on which steel works have relied lately, do not seem in such demand, on account of the feeling amongst tinplate makers that the McKinley tariff will press heavily on their trade. One furnace at Rhymney has been turned on to spiegel iron. The iron ore market is dull. Rubio ore of first quality is quoted at 13s. 6d. to 13s. 9d. c.i.f. Cardiff or Newport; second quality, 13s. to 13s. 3d.

Coal and Coke.—Shipping operations have been partially suspended on account of the snowstorm, which has also had the natural effect of reducing chartering transactions and sales. There is, however, a fair prospect for the summer months, judging from the number of inquiries for large quantities during the past few days. With the exception of small steam coal, quotations for all descriptions are firm at recent quotations. Steam coal (large) realises:—No. 1 quality, 14s. 6d. to 15s. 3d.; No. 2, 13s. 9d. to 14s. 3d.; No. 3, 13s. 3d. to 13s. 6d.; and No. 4, 12s. 6d. to 13s. Small steam, 5s. 3d. to 5s. 5d. The inquiry for coke is limited, furnace being offered at 20s. to 21s.; foundry, 23s. to 24s.; special foundry, 26s. to 27s. 6d. The supply of Pitwood is largely in excess of the demand, owing to heavy imports and low freights.

BARROW-IN-FURNESS, 11th March, 1891.

Hematite.—A quieter tone is again shown in the hematite pig iron trade this week, and only a very small amount of business has been done. Prices have dwindled down to 49s. 6d. for hematite warrants net cash, and makers are asking 52s. per ton for parcels of mixed numbers of Bessemer iron net f.o.b. Makers cannot produce iron at a less figure than this whilst the cost of raw material remains at its present quotation. Stocks have been diminished this week to the extent of 6,110 tons, and now stand at 199,676 tons, compared with 380,000 tons on January 1st, 1890. Forty furnaces are in blast and thirty-six standing idle.

Steel.—There is no change to note in the steel trade, and the only department in which there is any prospect of good trade is the Siemens-Martin department. Shipbuilders are expected to place good orders for plates and angles, and the Barrow Steel Company have determined to double their output of plates by the erection of a light mill.

Iron Ore.—Although the demand remains very slow, and although raisers of ore are stocking at the pits, prices are maintained at 10s. 6d. to 11s. 6d. per ton, but cheaper rates are expected.

Shipping.—The export trade in pig iron and steel is still depressed. During the week the shipments amounted to 15,053 tons, compared with 22,524 tons in the corresponding week of last year, being a decrease of 7,471 tons. The exports up to date this year represent 159,334 tons, against 187,938 tons exported during the same period of 1890—a decrease on 1891 of 28,604 tons.

Barrow Hematite Steel Company.—The report of the directors of this company shows a net profit of £132,314 during the past year. Of this sum, £18,194 is to be applied in defraying special expenditure upon the furnaces, steel works, and mines, and £25,000 is placed to the reserve fund. £4,616 is carried forward, and the remainder will be applied in paying dividends on the preference and ordinary shares. The report states that the capital account of the steel works has been increased by £7,197 2s. 10d. This sum represents expenditure upon new compressing machinery, a new machine shop for dealing with steel castings, and a hot metal mixer, the latter being for the purpose of obtaining a more uniform quality of iron taken from the blast furnaces to the steel works.

Chemical Wood Pulp.—The Kellner-Partington Pulp Company, at Barrow, has accepted the tender of Mr. Peters, of Rochdale, for a large extension at the works at Barrow. It is proposed to make not only the pulp, but also special qualities of paper for which there is a great demand.

MIDDLESBROUGH, 11th March, 1891.

Pig Iron.—There was a very large attendance on 'Change yesterday, but the market was dull and the tone despondent. Scarcely an order or inquiry was reported, and the only sales or purchases were for early delivery. The inquiry from the Continent is disappointing, and the present weather will not improve matters. For the present the demand from Scotland is well kept up. Merchants generally quote 41s. per ton for prompt f.o.b. deliveries of No. 3 G.M.B., and makers have asked and in some cases realised that price, but buyers, as a rule, would not give more than 40s. 9d. Middlesbrough warrants are at 40s. 7½d. buyers, and 40s. 9d. sellers. Forge pig is a little weaker, as the re-lighting of the furnaces in Scotland will ultimately cause a lessened shipment of Cleveland forge to Scotch works. The price is quoted at about 40s. per ton. Grey iron is 40s., mottled 39s., and white 39s., but buyers offer 3d. below these prices. East coast hematite pig is 53s. per ton at furnaces for mixed numbers. The stock in Connal's stores on the 9th inst. was 125,921 tons, an increase of 1,353 tons on the previous week.

Manufactured Iron and Steel.—No change has taken place since last week. Manufacturers are still able to keep their mills in regular operation, and do not reduce their quotations. Common iron bars and ship plates are £5 12s. 6d. to £5 15s.; best bars, £6 2s. 6d.; boiler plates, £6 12s. 6d.; ship angles, £5 10s.; engineering angles, £5 12s. 6d.; steel ship plates, £6; steel angles, £5 17s. 6d.—all less 2½ per cent. discount. Steel rails are very dull, and may be obtained at from £5 12s. 6d. to £5 15s. net at works.

The Coke Trade.—Good blast furnace coke can be bought here at 15s. to 16s. per ton, and the price is tending downwards.

Shipments.—The shipments are very well kept up, considering the weather, and amount to 19,190 tons for this month up to the 9th inst. Of this 12,910 tons have gone to Scotland, 2,100 tons to England and Wales, 2,100 tons to Germany, and 1,505 tons to other countries.

NEWCASTLE, 10th March, 1891.

The Coal Trade.—The very sudden change in the weather has, as might be expected, greatly stimulated the demand for household coals, and prices have in consequence been somewhat strengthened. In some other departments of the local coal trade a tendency to improvement may be seen, but this is, perhaps, attributable to the unsettled state of the trade in Durham, resulting from the long-continued strike at the Silksworth Colliery. The output at most of the Northumberland collieries is quite up to the average, and full time is generally being worked. The shipments of coal and coke at Tyne Dock for the week ending the 7th inst. amounted to 102,731 tons, being a decrease as compared with the shipments in the corresponding week last year of 2,105 tons.

The Disputes in the Shipping Trade.—In the struggle between the Shipowners' Federation and the Seamen and Firemen's Union the former is rapidly gaining the upper hand. At a large meeting of union men held at South Shields on the 9th inst. it was decided to accept the Federation programme, which simply pledges the holder to proceed to sea in any vessel he may "sign" for, whether the other members of the crew belong to a seamen's union or not. The number of steamers laid up in the Tyne increases daily, and cannot now be less than 120, representing an aggregate tonnage of 150,000 tons.

Stoppage of Work.—A very heavy fall of snow, which took place on the 8th inst., has caused a general cessation of operations in outdoor employments, the shipbuilding industry included. The number of men laid idle in the district cannot be estimated at less than 20,000, and as the stoppage of work is likely to last for several days, the loss to the industrial and commercial sections of the community will be very serious.

Overtime in Engineering Shops.—A conference between representatives of the employers and the operatives in the local engineering trade was held in Newcastle on the 10th inst., the object being to discuss a claim put forward on behalf of the men in reference to the restriction of overtime. The result has not yet transpired, but it was expected that a basis of settlement would be agreed upon.

DUNDEE, 11th March, 1891.

Jute and Flax Trades.—Business in both branches of the Dundee trade continues quiet. In the jute branch it looks as if production were in excess of requirements. The demand from South American markets is greatly curtailed, and prices are with difficulty maintained. Advices from New York indicate a weaker market. Burlaps, 40in. 10½oz., are quoted at 5c. per yard, and light weights at 4 13/16c. per yard. The linen trade is steady. In flax considerable sales on contract are reported. The market for flax and tow yarns has been rather active. Makers of linens are fairly busy, but canvas continues dull.

THE "KINGDON" INDUCTOR DYNAMO.

CONSTRUCTED BY MESSRS. WOODHOUSE & RAWSON UNITED, LIMITED, 88, QUEEN VICTORIA STREET, LONDON, E.C.

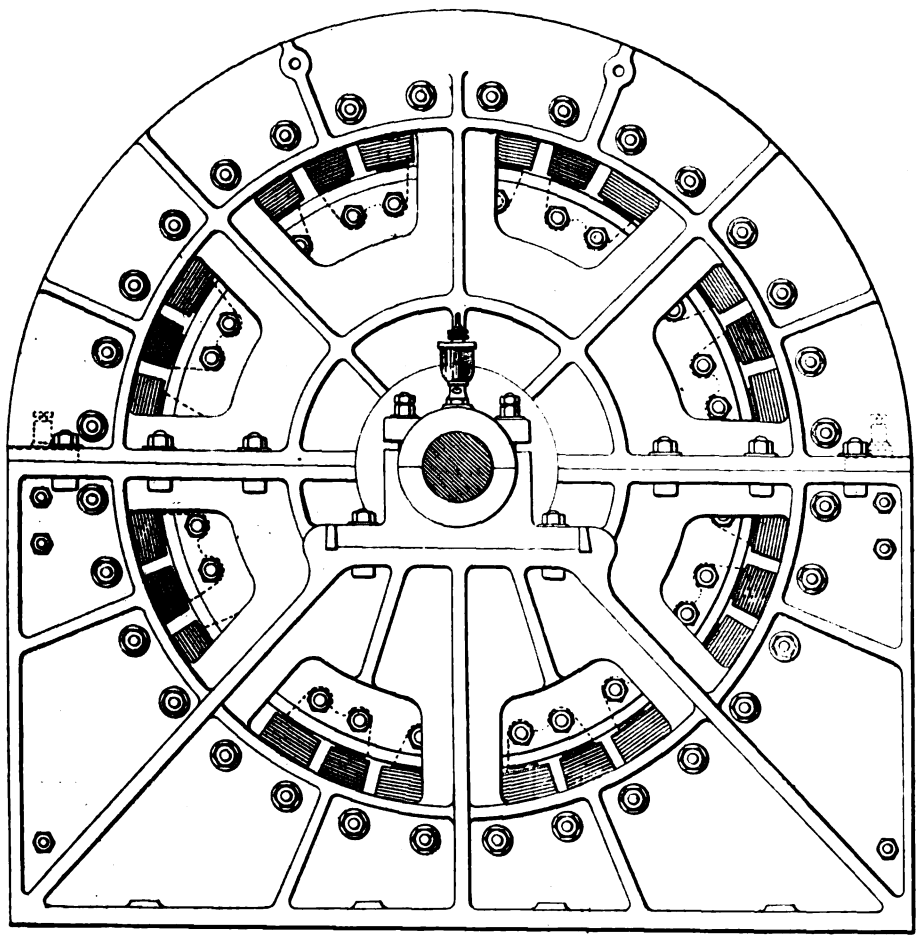

FIG. 1.—SIDE ELEVATION.

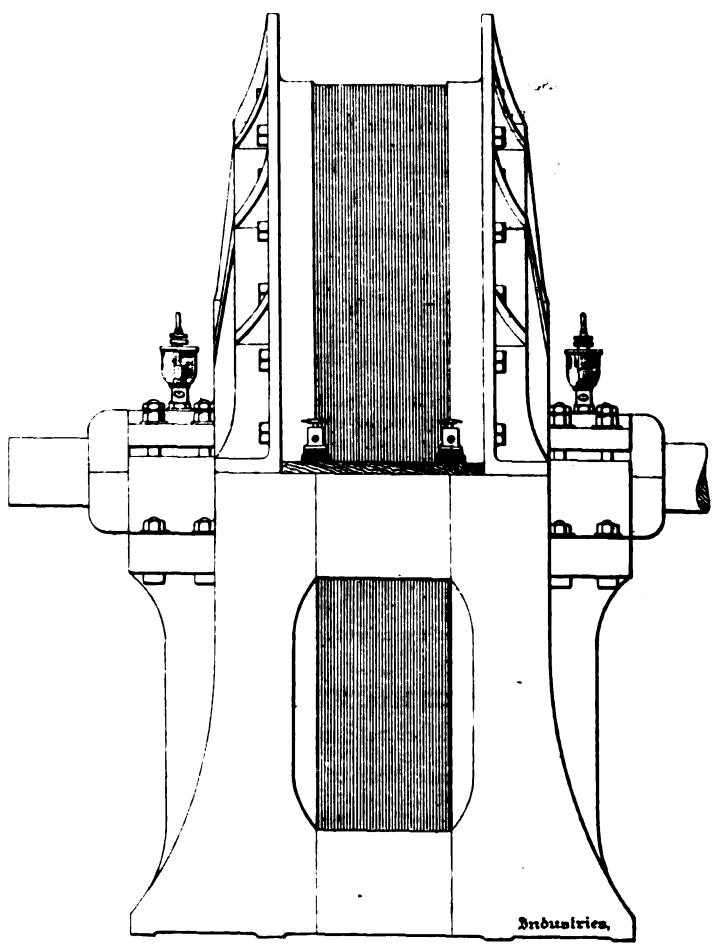

FIG. 2.—END ELEVATION.

THE "KINGDON" INDUCTOR DYNAMO.

THE illustrations given above (Figs. 1 and 2) represent one of the 70 unit alternating current dynamos designed by Mr. J. A. Kingdon for the central station at Woking. In this machine the coils, which correspond both to the armature coils and to the field magnet coils of an ordinary alternating current dynamo, are fixed, while the revolving wheel carries a number of

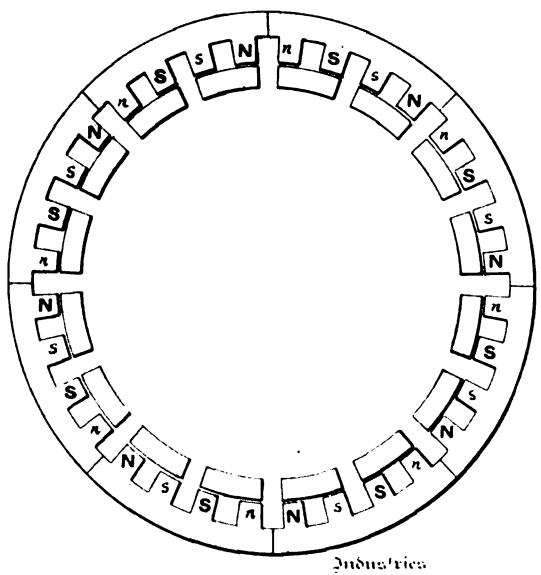

FIG. 3.

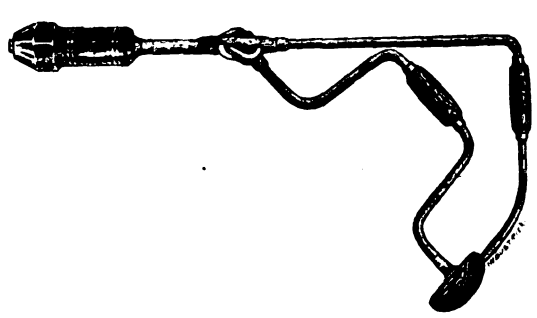
laminated masses of iron or inductors, which produce by their motion magnetic changes in the iron cores of the armature or secondary coils. The magnets of the dynamo are built up of a number of stamped iron plates, each plate being of the shape shown in Fig. 3, and having four projecting core pieces. These plates are bolted between two stout cast-iron frames, which also carry the pedestals. The machine is divided horizontally along the centre lines, so that the top can be lifted off and the wheel taken out. There are thirty-two magnet cores projecting from the magnet ring, and sixteen of these are fitted with the primary or exciting coils, and sixteen with the secondary coils in which the alternating current is generated, primary and secondary coils being placed alternately. In the diagram (Fig. 3) the poles marked N S N S are primary poles, and are magnetised by means of an exciter with the polarities indicated. The intermediate poles *n s n s* are the secondary poles, and have their magnetism constantly changed as the inductor wheel rotates. The number of inductors, which consist of a number of stamped iron plates bolted between two steel discs carried on a hub on the shaft, is sixteen, being equal to half the number of the magnet cores.



The action of the machine is as follows:—In the position of the wheel shown in Fig. 1 the secondary poles have the polarities indicated, being magnetised by the primary poles with which they are connected through the inductors. When the inductor wheel has rotated through one thirty-second of a complete revolution, the secondary poles will all have their polarities changed, being now magnetically connected through the inductors, each with the primary magnet on the other side. The inductor wheel thus acts as a magnetic commutator, and as it rotates continually changes the polarities of the secondary magnets. Alternating currents are accordingly generated in the coils wound on the secondary magnets. The polarity of the secondary magnets being changed thirty-two times during each complete revolution, the number of alternations per revolution is thirty-two, being equal to twice the number of the inductors, and being quite independent of the number of primary or secondary coils.

The dynamos at the Woking Central Station are coupled direct to triple-expansion engines running at about 260 revolutions per minute. The periodicity of the machines is therefore 70. Each machine is divided into halves, each half giving 15 amperes at 2,000 volts at the speed mentioned. Either the top half or the bottom half can be used alone or the two halves may be used together as one machine. When the load on a machine is less than 30,000 watts, one half only of the primary magnets are excited, and current is taken from the corresponding secondaries. The principal dimensions of the machine are:—Length, 6ft. 8in.; height, 6ft. 8in.; width, 3ft. 9in. The inductor wheel is 4ft. 6in. in diameter. The inductors measure 12in. by 8in. on the face. The magnets are 3in. long, and measure 12in. by 3in. on the face. The resistance of eight primary coils connected in series is 2·7 ohms, and of eight secondary coils 1·8 ohm. The total weight of the machines is about 7½ tons.

The Kingdon inductor dynamo is manufactured by Messrs. Woodhouse & Rawson United, Limited, of 88, Queen Victoria Street, E.C., at their heavy engineering works at Kidsgrove, near Crewe, where also the engines and boilers for the Woking Central Station were made.

THE "AMIDON" CORNER BRACE.

THE accompanying illustration represents a new corner brace made by Mr. C. H. Amidon, 1451, Niagara Street, Buffalo, New York State, intended for boring holes in corners, where the ordinary type of brace could not be used. As will be seen, the brace handle works at an angle with

the bit spindle by means of a Hooke's joint, the pressure being applied directly through the vertical arm instead of through the handle. The want of a simple brace of this description—particularly in electrical installation work—must have been long felt, and as the brace is equally adaptable for ordinary positions it should have an extended use. Our illustration is taken from the *Electrical Engineer* of New York.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 76, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 13TH MARCH, 1891.

RAILWAY WORKING EXPENDITURE AND RAILWAY RATES.

THERE are two items that give concern to every railway engineer, and which he is always endeavouring to bring under better control. The one, and the most important, of these is the item of labour; the second, which is hardly less important, is the price of materials. The average working expenditure per train-mile in the United Kingdom is about 2s. 6d., and of this amount probably fully 1s. 6d. is made up of the two items that have been named, leaving only 1s. to go towards the cost of fuel, general expenses, rates and taxes, and so forth. The recent labour disputes on the Midland and Scotch railways are likely to cause greater uneasiness in the future in reference to labour movements, but it would, perhaps, be unwise to attach too much importance to these circumstances, or to connect too closely the present unsettled condition of the labour market and the exceptional position of railway servants as regards long hours and low rates of wages. It is nevertheless evident that the railway companies themselves are by no means too easy about the matter, since they have attached special importance to the future relations of labour in the controversy they have lately had with the traders as to their maximum rates and charges, while they are preparing to insist on the same points with all the strength at their command in the inquiry that is about to be held on the Bills now before Parliament. So far as it is possible to glean the information from the somewhat defective returns embodied in the accounts of the railway companies, it would appear that the recent tendency of labour has been towards increased cheapness rather than towards a higher cost—taking for comparison a period of ten or twelve years. Whether this is due to any absolute decrease of the rate of wages, or to the working of longer hours by the individual, or to getting the functions of labour aided by mechanical auxiliaries so as to reduce the number of hands employed relatively to a given result, or whether all these and other causes combined have had something to do with the fact, we do not pretend to say with precision, but we give below a statement of the actual amounts paid for labour on the longest system in Great Britain—namely, the Great Western Railway—for the years 1877 and 1888:—

	1877.		1888.
Maintenance of way	£258,800	...	£229,600
Locomotive power running	277,200	...	356,900
Repairs and renewals	213,500	...	218,500
Carriages	56,000	...	95,500
Waggons	68,600	...	83,700
Traffic expenses	694,300	...	825,500
Totals	£1,568,400	...	£1,809,700
Train-miles run	25,709,200	...	31,708,500
Average wages per train-mile	1·26s.	...	1·16s.

Here, as between the two dates, we find an average reduction of about one-tenth of a shilling in the ascertainable amount paid for wages. The sums given above do not, however, include all the wages paid by the company, since there are many minor departments as to which no actual returns are available. The only thing that can be said is that, as the figures that have been adduced cover the greater part of the labour employed by the company, it is fair to assume that the remainder will follow the same tendency, and bring out a closely approximative result. And as with the Great Western, so, in all probability, with the other great lines of the United Kingdom, of which this particular system is fairly representative. Evidently, therefore, up to the end of 1888, the railway companies had not much reason to complain of the way in which they were effected by the general movement of the labour market, and this fact may be commended to the attention of the Labour Commission that has just been constituted, since no description of labour is more typical than that employed on our great railway lines. No doubt, since 1888, the cost of labour has increased as a general rule, but it has increased less in relation to railway working than it has done in relation to industrial operations generally, and it is not probable that the slight margin of increase that has undoubtedly taken place is likely to place the railway companies in a worse position in reference to the train-mile cost of labour than they occupied between 1873 and 1887.

The reduced cost of the materials that are used on a large scale in railway working has enabled the companies to show a remarkable economy over the period that has been selected for comparison. In this direction the companies have made more striking reductions than in any other. Comparing the returns of the same railway company for the same two years we find the following results:—

COST OF MATERIALS PURCHASED BY THE GREAT WESTERN RAILWAY.

For—	1877.		1888.
Maintenance of way	£413,556	...	£184,429
Repairs and Renewals—			
Of locomotives	131,536	...	141,145
Of carriages	54,030	...	72,270
Of waggons	78,985	...	77,754
Totals	£678,107	...	£475,598
Total train-miles run	25,709,200	...	31,708,500
Average per train-mile	6·31d.		3·60d.

The working out of a very simple problem in arithmetic will show that, if the company had expended the same amount per train-mile in 1888 that they did in 1877, the total sum paid for materials in the former year would have been £833,670 instead of £475,598, and this would apply, no doubt, with equal force to the other companies throughout the United Kingdom. The lower prices recently paid for railway materials have enabled the companies to have at their disposal a larger sum for improvements and alterations in other directions, but it is doubtful whether they have always wisely bestowed their surpluses thus obtained. But of the fact that the industries of the country have enormously benefited the railway companies by placing cheaper materials at their command, there cannot be any doubt whatever.

As the railway companies, in presenting their case before the Board of Trade, have made a good deal of the possible increase of expenditure entailed by the higher cost of labour and materials, it is well that the actual facts, as brought out in the above analyses, should be presented to Parliament. The railways of this country have paid relatively less for

Digitized by Google

labour, for fuel, and for materials of construction during recent years (excluding 1889-90) than they have ever done before, and this should have enabled them, but for their extravagance in other directions, to have reduced their working costs all round. It is to the traders, whom they now wish to saddle with the burden of higher rates, that they primarily owe these notable advantages, and it is to be hoped that the traders will not fail to see that Parliament is made acquainted with the details of this part of their case. The time is now close at hand when the railway companies' charter must be settled one way or the other. The Board of Trade have submitted what they believe to be satisfactory and equitable schedules, and a classification, that are perhaps not perfect, but certainly much better than those proposed by the companies. The Board of Trade look to the traders to support the proposals which they have put forward, and the traders would be unwise if they neglected the opportunity.

THE NAVY AND BRITISH COMMERCE.

The debate in the House of Commons on the motion proposed by Sir J. Colomb on the growth of colonial sea commerce, and the consequent increase of British responsibilities, did not excite very much interest among the members—at least, if we are to judge from the small number which attended. The motion suggested that the growth of the sea commerce of the British colonies and dependencies, and of the war fleets of foreign Powers, render it desirable that the annual Navy Estimates presented to Parliament should in future be accompanied by a return showing the total number of warships of each class in commission, in reserve, and building, the annual aggregate revenue, the annual naval expenditure, the aggregate tonnage of the mercantile marine, and the approximate annual aggregate value of the sea-borne commerce of the British empire, and of each foreign Power possessing warships, and a further return showing the annual naval expenditure on sea-going forces, and the approximate annual value, exclusive of interchange with the United Kingdom, of the sea-borne commerce of British North America, British South Africa, British Australasia, and British India respectively. All this looks a rather innocent request for information, but the tone of the speech by which it was backed was decidedly alarmist, and intended to show that our naval arrangements were not kept up to the requirements of our rapidly extending commerce. As to the latter, Sir J. Colomb pointed out that the outlying empire —that was to say, the empire exclusive of the United Kingdom—showed a value of exports and imports in one year of £460,000,000, of which the interchange with the United Kingdom was only £187,000,000, and, therefore, the independent trade of the outlying empire was £273,000,000. We were approaching a period when the sea-borne commerce of the colonies would exceed that of the mother country, and for that reason Sir J. Colomb submitted that the information for which he asked should be attached to the annual Navy Estimates, so that the House and the country, responsible for this gigantic empire, and the safety of this gigantic sea business, should be able to judge whether the preparations were adequate, and whether the Government were taking the steps necessary to secure these interests.

The First Lord of the Admiralty agreed to grant the return in a modified and condensed form, but he could not assent to the motion as it stood, as he found that the longer the documents presented to Parliament the fewer members read them. He differed from Admiral Colomb in the opinion that increase of commerce necessarily meant increase of naval danger. We ought, he thought, to try to keep up our Navy so that it would maintain in every part of the world its fighting supremacy, and for that purpose the Navy should be independent of any assistance from the merchant cruisers. Having performed that duty, we ought to give the most adequate protection possible to our commerce, and in that task our merchant cruisers could, to a certain extent, be associated with the Navy, and it was on these lines that the Government were now working.

Although Sir William Harcourt may have exaggerated the assistance which would be received from neutral flags in time of war, still, on the whole, we think that his remarks were needed by those naval members of Parliament who seem to think it is necessary to be constantly trying to induce the increase of the already enormous expenditure of the country on naval and military defence. He pointed out that during the past two years Her Majesty's Government had brought in two measures, one called the Imperial Defence Act, and the other called the Naval Defence Act, which provided for an expenditure of £24,000,000, and in that they had not merely made a present provision, but had really mortgaged the resources of the future.

There is nothing worse for the Navy than periodical panics, and even the most severe critics of the Government in naval matters admit that at present there is no cause for alarm. They have during their tenure of office done much to strengthen the Navy, and they have gained the confidence of the country by the business-like way in which they have gone about it. Our advice has always been to go on steadily maintaining the power of the Navy, and to show that we are conscious of our strength, and thus do much to remove the causes of the periodical alarms to which we are subject. The modified returns which have been agreed to by the First Lord of the Admiralty will be useful in showing that the policy which is being pursued both in the Navy and the mercantile marine is as much as reasonable men will be inclined to demand.

THE PROPOSED FORTH AND CLYDE SHIP CANAL.

The proposed Forth and Clyde Ship Canal, which has now been before the public for a considerable time, and to which we have several times directed the attention of our readers, has again been somewhat prominently brought into notice by the motion made by Mr. Wilson, representing the South of Scotland Chamber at the recent meeting of the Associated Chambers of Commerce, held in London, to the effect "that, seeing the establishment of a ship canal connecting the Forth and Clyde would be of great advantage to commerce between the Continent of Europe and all ports on the west coast of Britain and countries beyond, and that it would at all times be of national value, this Association urges the appointment of a Royal Commission to inquire into the merits and cost of such an undertaking." Mr. Wilson gave a sketch of the advantages and of the financial and engineering questions connected with the canal. These we have referred to on previous occasions, and therefore need not repeat them here. We may mention, however, that a very interesting *brochure* on the subject, especially in its relation to the development of commerce, by Mr. J. Law Crawford, has just been published by Messrs. Maclaren & Sons, Glasgow and London, in which will be found a report by the engineers of the route of which he is a supporter, and in which the importance of such a canal in time of war, and its value in the development of international traffic, is fully dwelt upon. We may simply mention that the proposal is to construct a ship canal 29 miles 6 furlongs and 196 yards long, 26ft. deep, and 100ft. wide at the bottom, capable of bearing on its waters large ocean-going steamers and men-of-war, and extending in a direct line across the narrowest part of Britain, from Yoker on the Clyde to Grangemouth on the Forth. Mr. Crawford estimates the cost at £8,000,000, and the annual income at £600,000. The promoters of the scheme had, we think, every reason to be satisfied with the amount of support which it received from the Associated Chambers of Commerce. Mr. Esslemont, M.P., however, pointed out that it was doubtful whether it was advisable to press upon the Chamber the expediency at the present stage of appointing a Royal Commission, as it required some discussion, and was a matter of great interest, as to whether it was going to be a Government undertaking. If it was to be a Government undertaking no doubt a Royal Commission would readily suggest itself, but it was a question whether the scheme could be taken out of the arena of private enterprise, especially as the sanguine engineers might really demonstrate that this was a commercially sound undertaking, and, if that were so, capitalists would find the money for it without Government intervention. He therefore suggested that the matter be considered for another year, and then they would have more information to go upon. This view was supported by the President and Sir Michael Hicks-Beach. The latter pointed out that it was not his business to influence their decisions because of his official position, but without expressing any opinion upon the real subject at issue, whether it was a work of general national importance or not, he might say that he did not see how it would be possible to defend the suggestion of a Royal Commission unless it was a work of national importance. Obviously, if it were merely a work that could be carried out, like the Manchester Ship Canal, by private capitalists, they would form the best commission for themselves. He thought the matter had been by no means sufficiently considered in the country as yet to justify the decision that it was a work of such national importance that the Government should aid it, and if the Government should not aid it, he could conceive no reason for the appointment of a Royal Commission. Ultimately the resolution was adopted, with the omission of that part referring to the appointment of a Royal Commission.

EXPLOSION AT DIXON'S IRONWORKS, GLASGOW.

An explosion, attended by the loss of at least five lives and the destruction of a considerable quantity of plant, took place on Tuesday at the well-known ironworks of Messrs. Dixon, Glasgow. The works are situated near Gushetfaulds Station, one of the stations of the Caledonian Railway on the confines of Glasgow. About three years ago plant for the recovery of sulphate of ammonia from the gas employed in the smelting furnaces was erected by the firm. The plant was designed and supplied by Messrs. R. & A. Dempster, of Manchester, and was of capacity sufficient to deal with 60,000,000 to 70,000,000 cubic feet of gas per day. During the suspension of pig iron production the works were wholly idle. Only a few weeks ago the furnaces in the district began to be re-lighted, though only a fourth of the normal number had yet been set going. At Messrs. Dixon's, although several furnaces had been re-lighted, the apparatus for the recovery of ammonia was only on Tuesday being put into working order preparatory to its being used. The manager, the foreman engineer and his assistant, the two latter being brothers, along with several men, were engaged in the work when the explosion occurred, by which the manager, three engineers, and a workman were killed, others being more or less seriously injured. It appears that the works had been unused for about five months, and that air had been blown through them at intervals in order to secure that no gas remained in the condensers or in the scrubbers. The details are not yet fully obtainable. It is said by one witness that the gas had been turned on, and by another that it had not. That there must have been gas in the apparatus is, however, certain. The immediate seat of the explosion was a tower, one of a series of five about 150ft. high, and this tower was partially destroyed by the explosion, the upper half having been completely demolished. The men who were killed were found at the foot of the tower buried in the *débris*. The work of attempted rescue was attended with no little difficulty, since minor explosions occurred at intervals until the gas was exhausted.

THE LATE MR. J. L. STOTHERT.

Mr. John Lum Stothert, for more than thirty years the principal member of the firm of Messrs. Stothert & Pitt, of Bath, died on the 5th inst. His health had been failing for several years, but no immediate danger was anticipated two days previously to his death. Although he had relinquished for some time much of the active business of the firm, he retained to the last the chairmanship of the company. Mr. Stothert was a man of great energy, and shrewd practical common sense. He was a mechanical engineer of the old school, and the well-established reputation of his firm is due to the fact that he would tolerate no inferior workmanship. The reputation of the firm for cranes and for block-setting machinery for harbour works is well shown in the works at Jersey, Madras, Mandaree, Colombo, Tynemouth, Hartlepool, Douglas, and those going on now at Peterhead. During the Bath meeting of the British Association in 1888 Mr. Stothert worked indefatigably as one of the hon. secretaries. It says a great deal for Mr. Stothert's tact in the management of men, that during the thirty-five years in which he was engaged in business he never had a strike or any serious dispute with his workmen. Mr. Stothert was a devoted student of astronomy. He had a well-appointed observatory in his grounds. This, with a private little workshop, fitted with some of the best English and American tools, occupied his leisure movements. Mr. Stothert died in his sixty-third year.

CLYDE SHIPBUILDING FOR FEBRUARY.

With regard to new contracts, business was altogether much quieter than in the preceding month, the amount of tonnage secured being only 12,000 tons—a little more than half the aggregate output. The largest order was booked by Messrs. William Denny & Bros., Dumbarton, for a steamer 430ft. long and of 6,500 tons, for the dead meat trade of the New Zealand Shipping Company. The same firm also contracted to build three other steamers, each of about 200 tons. Orders aggregating 3,500 tons were placed with Messrs. Scott & Co., Greenock, which include two twin-screw and two single-screw steamers, for general trading purposes; and Messrs. Blackwood & Gordon, of Port Glasgow, were instructed to build a twin-screw steamer of 1,400 tons, for a London firm. The output of tonnage reached a total of 22,710 tons, and included eleven steamers, of 13,650 tons; five sailing vessels, of 8,310 tons;

Digitized by Google

and five barges, of 750 tons. Considerably more than one-third of the total tonnage launched was built for German owners, and the principal steamer contributing to the month's output—the "Weimar"—was launched from the stocks of the Fairfield Shipbuilding Company, Govan, for the North German Lloyd of Bremen. The dimensions of this vessel are:—Length, 431ft.; breadth, 48ft.; depth, 33ft.; and tonnage, 5,400. Her engines are of the triple-expansion type, with three cylinders of 31in., 52in., and 83in. in diameter respectively, with a stroke of 54in. The high-pressure cylinder is fitted with a piston valve, while the medium and low pressure cylinders are each fitted with the ordinary double-ported slide valves. Two double-ended and two single-ended boilers are fitted to supply steam at a working pressure of 150lb. per square inch.

The third of the second-class twin-screw cruisers built by Messrs. J. & G. Thomson, of Clydebank, for the British Admiralty, was launched during the month. She is in every respect similar to her sister ships, "Thetis" and "Terpsichore," being 300ft. in length, 43ft. in extreme breadth, with a displacement of 3,400 tons on a mean draught of water of 16ft. 6in. The propelling machinery consists of two sets of triple-expansion engines, capable of developing 9,000 horse-power under forced draught, from which a speed of 20 knots is expected.

The following are the particulars of vessels launched during the month:—

SINGLE-SCREW STEAMERS.

"Esmeralda" (steel), 1,500 tons, built by Messrs. William Hamilton & Co., Port Glasgow, and fitted with triple-expansion engines by Messrs. Hutson & Corbett, Glasgow, for Messrs. A. Russell & Co., London.

"Gnat" (iron), trawler, 150 tons, 300 horse-power, built and engined by Messrs. Mackie & Thomson, Govan, for the North Sea fishing trade.

"Norman" (iron), 300 tons, built by Messrs. M'Gill & Co., Irvine, for Messrs. J. & G. M'Farlane, Glasgow.

"Premier" (steel), 200 tons, built by Messrs. S. M'Knight & Co., and fitted with compound surface-condensing engines by Mr. W. Kemp, Govan, for Mr. J. Wood, Halifax, Nova Scotia.

"Rover," sister ship to the "Gnat," by the same builders.

"Somerville," sister ship to the "Gnat," by the same builders.

"Sheik Borkhud" (steel), 400 tons, 500 horse-power, built and fitted with triple-expansion engines by Messrs. Scott & Co., Greenock, to the order of the Perim Coal Company.

"Weimar" (steel), 5,400 tons, built and fitted with triple-expansion engines by the Fairfield and Shipbuilding Company, Govan, to the order of the Norddeutscher Lloyd, Bremen.

Steel screw steamer, 1,500 tons, built by Messrs. Wm. Denny & Brothers, Dumbarton, and fitted with triple-expansion engines by Messrs. Denny & Co., for the Union Steamship Company, Dunedin.

TWIN-SCREW STEAMERS.

H.M.S. "Tribune" (steel), 3,400 tons, 9,000 horse-power, built and fitted with triple-expansion engines by Messrs. J. & G. Thomson, Clydebank, for the British Government.

Steel dredger, 500 tons, 500 horse-power, built and engined by Messrs. Wm. Simons & Co., Renfrew, to the order of the French Government.

SAILING VESSELS.

"Baroda" (steel), barque, of 1,350 tons, built by Messrs. Archibald McMillan & Sons, Dumbarton, to the order of Messrs. W. & J. Crawford, Greenock.

"Centurion" (steel), four-masted ship, of 1,700 tons, built by Messrs. Russell & Co., Port Glasgow, for Messrs. G. T. Soley & Co., Liverpool.

"Gowanbank" (steel), four-masted ship, of 2,200 tons, built by Messrs. Russell & Co., Port Glasgow, for Messrs. Andrew Weir & Co., Glasgow.

"Othmarschen" (steel), 1,700 tons, built by Messrs. Chas. Connell & Co., Scotstoun, for Hamburg owners.

"Pax" (steel), barque, of 1,360 tons, built by Messrs. Russell & Co., Port Glasgow, for Mr. J. H. Hastede, Elsfleth, Germany.

In addition to the above, Messrs. Murdoch & Murray, Port Glasgow, shipped five lighters, each of 150 tons, to Rio de Janeiro.

Letters to the Editor.

THE LONDON SMOKE AND FOG PLAGUE.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Your correspondent, "B.B.," in the opening part of his letter, adds an eloquent argument in favour of action in some way to remove the Smoke and Fog Plague of London. Those who have a highly nervous temperament undoubtedly suffer most from the devitalising influences of an ambient atmosphere, impregnated as it is with carbon atoms, carbon monoxide, sulphuric acid, &c., in combination with the vaporous results of organic exhalations.

The vitality and electric influences of the solar rays are practically destroyed by the non-conducting layers overhanging London, and thus the atmospheric oxidising influences (by which the organic suspended matter at the breathing level is rendered effete and harmless) are arrested, so that the fatal effects of fog and smoke are widened, and are thus difficult to calculate with precision, but the number of deaths and extent of disease attributable to the modern London plague must be sought for in other classes than the merely respiratory and even zymotic ones.

Your correspondent, "B.B.," asks a question which, I think, rather premature at present, as to the manner in which it is proposed to carry out the undertaking. This will probably be determined either by the London County Council or by the present Metropolitan Gas Directorate in combined union.

If the London County Council decide to promote the scheme, which is worthy of their attention in a greater and more urgent degree than is the proposal to acquire the London water supply undertakings, and would be far and away more lucrative, the ordinary Parliamentary procedure for obtaining the necessary borrowing powers would, of course, have to be followed.

If the Metropolitan Gas Directorate syndicate the scheme, they already have existing powers to carry out a great part of the work necessary. These powers could be extended to the required extent. There would of course be the usual opposition of vested interests; but if London is fairly unanimous the opposition would clear away like a smokeless mist before the sun. There would, I believe, be no difficulty in obtaining the necessary capital to carry out the undertaking. The actual money expenditure on Metropolitan and district gas undertakings is said to exceed 17 millions sterling, whereas my alternative project is estimated to cost 10¾ millions only.

If the Gas Directorate carry out the project, part of the existing generating plant and distributing arrangements would remain intact. At present the gas companies of the Metropolis deal with, say, ⅓th of the total annual weight of the fuel consumed in the Metropolis; the fuel gas project would require to deal with the ⅓th of the fuel now used in the solid form.

Although the thermic *raison d'être* of heating proposed by "R. S." is more adequate than the usual open grate system, I am quite sure that the majority of the London citizens will still cling to the Englishman's and Scotchman's hearth with its many episodes, so closely associated with our domestic history

> But a sight sae delightfu' I trow I ne'er spied,
> As the bonnie blythe blink o' my ain fireside.

Our hearths and cheery firesides are words that have a meaning too dear to be obliterated in our age.

> See, the fire is sinking low,
> Dusky red the embers glow.
> * * * *
> Every quivering tongue of flame
> Seems to murmur some great name.
> * * * *
> Then the flicker of the blaze
> Gleams on volumes of old days.
> * * * *
> Suddenly the flame sinks down;
> Sink the rumours of renown.

Mr. Armer in his letter points out the advantages that would accrue to the middle classes by the carrying out of the project; it would restore peace in many a household disturbed by incessant internal conflicts with servants, owing to the existing dirty and barbarous system of obtaining heat for domestic requirements. As Mr. Armer suggests, there is no reason why the large provincial towns adjoining the main pipe lines should not be fed with fuel gas and even lighting gas if required. It is simply a question of supply and demand; if there was sufficient demand to warrant the laying down of an extra pipe this could be done. As to the question of the main pipe line, consisting of three service mains of 5ft. diameter, calculation, and actual data of experience, show me there need be no difficulty, especially now that light and reliable mild steel plates at a low figure and economic electric welding are features easily obtained.

The residual nitrogenous recovery plant would produce the nitrogenous constituents, ammonia sulphates, in the centres of agriculture, and where wanted.

In reply to Dr. Bailey's important contribution to the discussion, his remarks as to the deadly character of the smoke plague should produce a lasting impression on all who read them, and clench with ponderous force the hygienic argument in favour of the project. It is sad to know that Manchester, the city of Dalton, Joule, and Whitworth, should be also afflicted with a plague even more deadly than that of London. I am quite sure that, if Dr. Bailey explains the meaning of the statistics he gives to Manchester men, some steps will be taken to carry out a scheme similar to that suggested for London. Once the City Council recognised the fact that the existence of an avoidable system which they control is fatal to life, they will endeavour to remove it, because they are morally just as responsible for deaths that occur from an avoidable and mischievous system, which they have power to control and alter, as are the owners of defective machinery that kills the workpeople. In the latter case legislation has brought in a measure of recompense, but there is no penalty for the evasion of municipal or civic duty.

Dr. Bailey states that the coalfields are nearer to Manchester than they are to London. This is quite true, but in the application to London there is an initial financial advantage of a greater margin of profit owing to the increased cost of carriage. This profit alone would justify the expenditure necessary to carry out the project. The cost of coal in London is about double that of Manchester, and if the project is to go through at all, it will be due principally to the fact that not only will its accomplishment abolish the black fog and smoke plague, but it will effect an enormous profit, by which much of the startling misery of East London might be relieved; besides, the architectural beauty of the London and Government buildings would be cleared from its mask of soot, and the rays of the sun could rest occasionally on the faces of London's almost countless citizens.

> But for the smoky Fog, the Sunbeam then would go
> Into the darkest places, all filled with want and woe,
> Until sad hearts look'd upwards—there would it brightly shine—
> Shine till they thought of heaven, their sweet home and thine.

I quite agree with the last paragraph in Dr. Bailey's letter to the effect, that no scheme, lacking in thoroughness and completeness of application, would be an adequate remedy for the evil.

Since writing the foregoing, other letters of more or less sympathetic criticism and support have appeared, and require answering. Some of them have already received attention by anticipation. In "F. G. D.'s" communication the part of his letter not already answered in the original articles is that referring to the amount to be paid for existing vested interests. This question of compensation has already been settled by the fate of the Bill to compensate publicans. Any existing trade or industry involving in its carrying on a national waste, and a standing injury or danger to the health of the neighbouring residents, can be justly suppressed, without compensation. Do the Government compensate the owners of industrial undertakings proved by the noxious vapours inspectors to be an insupportable nuisance? If this indictment is proved, the works are summarily stopped by injunction, and no compensation is allowed, and, therefore, I am fully justified in neglecting the compensation feature in my estimate of the cost of the pipe line project. "F. G. D." will observe that I do not propose the hot air from basement system of heating.

"D. H. N." gives an explanation of the exorbitant prices charged to the London poor for coal. Undoubtedly if the proposed project became *un fait accompli*, and the penny prepayment system was adopted, this would prove a great boon to the "submerged tenth," and to the denizens of the East End, and the occupation of the gang of "coal Shylocks" would be gone. "D. H. N." emphasises the fact that should not be forgotten by Londoners—viz., that the great profits earned by the gas departments in the Northern and Midland provincial towns go a long way towards meeting the annual cost of the other and sanitary departments, and if London is to have its sewage scheme enlarged, and this will cost, according to the engineer's estimate, £8,000,000 sterling and £80,000 a year for maintenance—and if the London water supply undertakings are also to be acquired by the London County Council—taxation in London will run up to a very seriously high figure unless such a project as that I propose is carried out, by which the London government would be enabled to secure an annual and considerable profit. The water supply department will only be able to cover its expenses, and the sewage scheme will be a dead financial loss and yearly outlay, so that Londoners had better commence to inquire who is going to "pay the piper."

In reply to Mr. Jesse Lovett's interesting communication, I do not doubt but that the project will eventually be carried out by some combination of the gas companies with the London County Council.

This might be effected as follows:—The present gas undertakings and distributing systems to be purchased right out by the London County Council for a figure to be determined on—say, £30,000,000—on the understanding that the London County Council bonds equal to this amount, and bearing the usual corporate rate of interest, should be accepted by the present shareholders of the gas companies as purchase money. The necessary additional capital—say, 10¾ millions—to be borrowed at the usual corporate rate of interest—say, 3 per cent.—to enable the complete project to be carried out. By this arrangement the whole of the gas undertakings and the complete carrying out of the project would be exceedingly simple, and its adoption would smash any opposition of vested interests.

It may be mentioned here that a low-priced heating gas would be a boon to the electric lighting companies for gas motor purposes. This would enable the central electric lighting stations to be more numerously and conveniently established, and thus reduce the loss of electric efficiency by conductor resistance and waste by leakage.

Mr. Lovett asks the pertinent question as to the calculated price per 1,000 cubic feet of the proposed cheap heating gas. This all depends upon the photometric and calorific value of the gas supplied. If a low luminous value of gas is produced it might be supplied to customers at prices varying from 1s. to 1s. 2d. per 1,000ft.; if 8-candle gas, from 1s. 3d. to 1s. 6d. per 1,000ft. might be charged, and of 12-candle gas, from 1s. 7d. to 1s. 11d. would be the probable cost. So much will depend upon the Government restrictions as to quality, that it is impossible to closely calculate and define the selling price of the fuel gas.

The objections raised in some quarters to the modern open gas fires are not justified. Given a cheaper gas and a higher gas pressure, there should be no difficulty in converting the present gas fires so as to radiate an average thermic value equal to an ordinary coal fire, which has an attribute of variable efficiency. With cheaper gas there will be no insuperable difficulty in increasing the heat producing and radiation area of the gas fire so as to compensate for the inferior local intensity. I should think Mr. T. Fletcher, or Messrs. G. Wright & Co., and others, with their experience, might demonstrate the possibility of this in a manner to satisfy the most exigent.

I fully appreciate the suggestion of Mr. Lovett that the plant should be, if not actually in duplicate, of such an approach to comprehensiveness of detail, that if one element should fail another can be immediately put on. He will also notice that the pipe line will be on the tripartite plan. This enables each generating station to have its own distributing main, and allows higher pressures to be established with less weight of metal thickness of conduits. Mr. Lovett considers that the railway and carters' interests would be met by Mr. Armer's proposed modification, but why perpetuate the costly and wasteful absurdity of carrying a material that can be made to travel in gaseous form? Just as foolishly perpetuate the old town pump and water-carts, instead of the present water distributing systems from watershed sources miles away from the place of consumption to where it is piped. Mr. Lovett's last paragraph, by logical incidence, shows that the financial proportions of the scheme would not throw it out of the area of practical application.

I fully concur in all that "B. B." states in his second letter.

The subject heading of this correspondence has recently been before both Houses of Legislature, and has been acknowledged by the Press to be the dark, if not the burning, question of the hour. It is proposed by Lord Campbell's Act to invade the

Digitized by Google

sanctity of the Englishman's castle to remove or abate the smoke evil, but, as Lord Salisbury justly inferred, the law will become a dead letter, and prove worse than useless. Englishmen will endure the smoke fog rather than have their privacy encroached upon by officious smoke inspectors. No; let us couple legislative enactment with the production of a cheap fuel gas and its distribution to every house, compelling by this legislative enactment the general use of this cheap gas, or of a smokeless substitute, and then the demon smoke fog will be exorcised once for all.

Mr. James Knowles, of the *Nineteenth Century*, has proposed in the non-technical press a midway scheme alternative to that of mine. Mr. Benjamin Ward Richardson goes nearer in his suggestion to the scheme I have outlined. A technical contemporary infers that "the only true remedy is to draw the smoke from the chimney into specially constructed savers." I leave this latter proposal to the judgment of your readers. I confine myself to the remark that such a proposal can hardly have been made seriously. If it has been, calculations and chemical considerations will show it to be impracticable and absurd in the highest degree.

Yours, &c.,
B. H. Thwaite.

Liverpool, 9th March, 1891.

THE PRESENT POSITION OF THE ALKALI TRADE.

To the Editor of "Industries."

Sir,—May I beg a little more space in which again to refer to the above subject? And first let me ask readers to substitute "to" for "in" in lines 8, 10, and 13 of the third paragraph of my letter printed in your issue of the 27th ult.

In your foot-note to my last letter you quote an opinion that "the struggle between the older and newer processes is no longer doubtful," and you add: "The words 'newer processes' will, we take it, be quite clear to the mind of our correspondent." Will you allow me to say, without any equivocation or reserve, that to the best of my knowledge and belief the products which, as stated in my letter of the 25th ult., are the basis of the Leblanc alkali trade—viz., caustic soda, bleaching powder, chlorate of potash and sulphur—are not made commercially by any other "newer processes" than those worked by the United Alkali Company. In fact, if we leave out of account the old Sicilian sulphur trade and a very small quantity of caustic soda made from cryolite, it would be almost literally true to say they are not produced by any other processes, either new or old.

The expression "newer processes" in the quotation given can only refer to the ammonia soda process, the success of which (in this country at least) is so well known. But that process produces only soda ash, and not any of the above-named principal products of the Leblanc process. And to say that because the manufacture of soda ash by the ammonia soda process is more profitable than the production of caustic soda, bleaching powder, chlorate of potash, and sulphur by the Leblanc process, therefore those engaged in the latter industry should abandon it and adopt the more remunerative process, would be as illogical as to argue that because the smelting of copper is more profitable than the making of iron or steel, therefore iron and steel smelters should demolish their costly plant and enter the copper trade. Or, to carry the analogy a step further, it would be almost as absurd as to reason that because shipping pays (let us say) 15 per cent., while railways average only (say) 5 per cent., therefore railway companies should dispose of all their valuable property of every kind and invest the proceeds in steamships.

The world still needs bleaching powder, chlorate, &c., but does not require an unlimited supply of ammonia soda ash. If those engaged in producing the former could, by some stroke of magic, transfer their capital to the latter industry, that very transfer would entirely alter the relative positions of the two processes, so far as their profit-earning power is concerned, and the last state of the said capitalists would be worse than the first.

Yours, &c.,
M.

Newcastle-on-Tyne, 6th March, 1891.

[By a slip, which we regret, the word "process," in the brief note appended to our correspondent's last letter, was printed "processes." The "newer process," in the official report from which we quoted, refers, of course, to the ammonia soda process, and we admit, with our correspondent, that caustic soda, bleaching powder, chlorate, and sulphur are not at present made by it. Both processes are, however, primarily soda ash processes, and in this respect the ammonia soda has beaten its predecessor, and it could readily manufacture caustic soda if the Union gives it the opportunity. Our correspondent defends the Union on the ground that bleaching powder, chlorate, and sulphur are still needed by the world; but we have in our review for the year, and in our article, endeavoured to show that the world is not needing these things in the same sense as formerly. There is a tendency for bleaching powder to be replaced by caustic, by hydrogen peroxide, by ozone, and by bleaching products, made direct from magnesium and calcium chloride by electrolysis, not to speak of the patents of Solvay, Eschellmann, Weldon and Pechiney, Wilde and Rechler, Mond, and many others, which, although not worked commercially, would, no doubt, be attempted, if there was a belief in the lasting nature of the demand for bleaching powder or in the permanency of the Union. There is also a tendency for chlorate to be made at Stassfurt in combination with some one or other of these various processes, and there is a possibility of sulphur being produced by the Chance-Claus kiln from coal gas, as well as from alkali waste. It is these various indications of progress in alternating processes which induced us to state in our article that the Leblanc process as such was dying, and that the Union can only be a success by affiliating some or all of these, as they become successful.—Ed. *Industries.*]

MR. KAPP'S CANTOR LECTURE.

To the Editor of "Industries."

Sir,—In your issue of the 27th ult. the Secretary of the General Electric Power and Traction Company, Limited, at the request of his managing director, publishes a correspondence in which it is stated that the Tables IV. and V. of Cantor Lecture given by Mr. Kapp at the Society of Arts, on Monday, the 16th ult., are entirely misleading, &c.

Now Table IV. shows the cost of the equipment of the Barking Road line with half a dozen 52-passenger accumulator tramcars, carried out by the writer in the spring of 1889 for the Electric Traction Company, Limited, every item of which is accurate, and their details can be furnished, the amount being £6,191 16s. (see *Industries* of February 20th). The cars proper are not included in the table, as only those items connected with the running expenses are dealt with. To include the cars would add £1,200 to the total, making it £7,391 16s., which is, perhaps, not what is desired.

Table V. gives the running expenses for the full mileage of the line—*i.e.*, five cars in service running a total of 100,844 miles per annum, being 8·068d. per car-mile. This corresponds to the year ending June 30th, 1890 It is accurate. It must also be very nearly true, indeed, for the present time, since the five most important items—namely, batteries, wages at depôt, drivers, fuel, steam plant—remain unchanged, and these five items represent 88 per cent of the total. The life of the batteries is ten months, or 300 discharges up to present time. The cars have now been on the road twenty-one months, and are working with their second renewals. It is to be hoped that the K type plates may prove more durable; the end of present year will show their merits or demerits as compared with the ordinary type. It is to be observed that the 8d. per car-mile corresponds to the full mileage of 100,844 miles per annum, and that the wages at depôt are a fixed charge—£677 6s. a year.

The mileage run during the first half-year of 1890, under the charge of the writer, was 44,047 car-miles. The mileage run during the second half-year (the installation now becoming the property of the General Electric Power and Traction Company, Limited) was 33,794 car-miles, or a decrease in miles run, period for period, of 10,252. Is this a measure of the improvements? This low mileage runs up the proportion of shed wages from 1·612d. to 2·407d., making the car-mile run 8·861d., which is unpleasantly near to 9d.

I must remind Mr. Mackenzie that I left the Electric Traction Company, Limited, at the time of its liquidation, and was in no way connected with the company to which he is secretary.

Yours, &c.,
T. Frazer.

114, Broadway, Plaistow, London, E.,
5th March, 1891.

To the Editor of "Industries."

Sir,—I regret to be compelled again to trouble you upon this subject, but if Mr. Kapp intends to convey the impression, which I presume he does, that on his visit to the Edinburgh Exhibition he found Mr. Frazer acting as cicerone on behalf of this company, it is my duty to point out to Mr. Kapp that Mr. Frazer was never employed either by the old Traction Company or by this company in any capacity whatever at the Edinburgh Exhibition. The engineer in charge of our installation was Mr. Lloyd B. Parsons.

On the occasion of the inspection of the launches run by my company on the canal at Edinburgh, Mr. Frazer was, by our courtesy, a passenger on the boats like other members of the Institution of Electrical Engineers. I am, therefore, quite at a loss to understand how Mr. Kapp could have made such a mistake as to Mr. Frazer's position there. In all the Press reports of the visit of the Engineers on that occasion, I do not find any mention made of Mr. Frazer having acted in the capacity of cicerone. Mr. Frazer himself states in his published letter that he was in no way connected with my company.

I have to thank Mr. Kapp for his offer to publish the authorised figures of the Barking Road installation. When my Board think it advisable to do so I shall have no difficulty in bringing them before the public. The effort that is being made to prove that five cars cannot operate at the same cost as 300 is quite unnecessary. I would only add that in response to invitations from various tramway companies and corporations owning tram lines my company have been and are issuing tenders to electrically equip and maintain tram lines by the overhead, conduit, and accumulator systems. If electric traction by accumulators were more expensive than horse traction the North Metropolitan Tramways Company, who have now had something like two years' experience of the work of these cars, would not be, as they are at present, applying to Parliament for powers to extend the system at a capital outlay to themselves of £50,000.

Yours, &c.,
W. J. M. MacKenzie, Secretary.

The General Electric Power and Traction Company, Limited,
New Broad Street House, 35, New Broad Street,
London, E.C., 9th March, 1891.

Legal Proceedings.

Pinto *v.* Badman.

This was a case tried in the Court of Appeal in connection with a trade mark action tried by Mr. Justice Day and a special jury in the Court of Queen's Bench in January last, of which we gave our readers a report at the time (see *Industries*, Vol. X., page 112). It will be remembered that in the Court below the jury found a verdict upon two issues to the effect that the trade mark used by the defendant was a colourable imitation of the plaintiff's trade mark, and that the defendant had been guilty of fraudulently passing off as and for the goods of the plaintiffs goods which were not his. From that judgment the defendant appealed upon the ground, among others, that the plaintiff's trade mark had been improperly registered. The appeal was supported by Mr. J. Fletcher Moulton, Q.C., Mr. J. W. Willis Bund, and Mr. Herbert Reed. For the respondent-plaintiff in the Court below appeared Mr. Aston, Q.C., and Mr. McCall, Q.C.

For the appellant it was argued that the plaintiff had no registrable interest in the trade mark because he had acquired from his predecessors in title only a right to use the mark, and not the goodwill, of the business in connection with which the mark had been used. In proof of this reference was made to the deeds by means of which the plaintiff had deduced his title to the mark, and it was contended that these deeds amounted to an assignment of the mark "in gross"—that is to say, by itself, and not as a mere part of the goodwill of a business which was being sold. The deeds being drawn up in Spanish, and executed in Mexico, some difficulty was experienced by the Court in coming to any conclusion as to their effect, but eventually it was held that they conveyed, as has been said, no goodwill or business, but only an independent right to the use of the mark. This being so, it was held that the registration was bad, and that the plaintiff, therefore, was not entitled to maintain the action in which he had recovered judgment. The judgment was accordingly reversed and entered for the defendant, but without costs.

The principle embodied in this decision is of the very greatest importance in trade mark law, and should be constantly borne in mind in any transactions in which the transfer of rights to such marks is involved. It is in the public interest, and not in the interest of the parties, that the rule has been laid down that a trade mark shall not pass without the trade to which it is attached. The reason of this is plain enough. It is no doubt greatly to the interest of the owner of a trade mark that the public should recognise the brand as designating his goods, but it is so because and only because it is to the interest of the purchaser to be able by this means to identify the article which he is purchasing. Now, if the owner of a trade mark were at liberty to sell his mark while he retained his trade, it is clear that the public might be deceived by having the whole meaning of a known mark surreptitiously altered. This might not matter to the contracting parties, but it would amount to a fraud upon the public, and for the repression of such fraud the rule has been introduced. The present was a very striking case of its application. There was no evidence that the assignment was not perfectly valid. According to the law of Mexico—the country in which it had been executed—it was admitted in the fullest possible manner that the person originally entitled to the mark who had assigned it to the plaintiff had parted with his own rights, but nevertheless, as the title which the plaintiff set up affected the rights of the British public, it was held that the transaction and the registration founded upon it could not be supported in a British court of law. There seems no room for doubt that the judgment correctly expresses the law, and it must be taken therefore that in no circumstances will the courts be likely hereafter to depart from the strict principle which has been so emphatically asserted in the present case.

Books Received.

Reports and Statistics of the Mining Department of Victoria for the Quarter ending September 30th, 1890.

The "Electrician" Electrical Trades Directory and Handbook for 1891. London: The *Electrician* Printing and Publishing Company.

Ventilation. By Wm. Paton Buchan. London: Crosby Lockwood & Son.

A Treatise on Chemistry. By Sir H. E. Roscoe and C. Schorlemmer. Vol. III. London: Macmillan & Co.

First Principles of Electrical Engineering. By C. H. W. Biggs. London: Biggs & Co.

Lockwood's Builders', Architects', Contractors', and Engineers' Price Book for 1891. Rewritten and edited by Francis T. W. Miller. London: Crosby Lockwood & Son.

Mineral Resources of the United States for Calendar Year 1888. T. David, Chief of Division of Mining Statistics and Technology. Washington: Government Printing Office.

Hydraulic Machinery Employed in the Concentration and Transmission of Power. By G. Croydon Marks, A.M.I.C.E., M.I.M.E. Manchester: The Technical Publishing Company, Limited.

Annual Report of the Postmaster-General of the United States for the Fiscal Year ending June 30th. 1890.

The Electro-Platers' Handbook. A Practical Manual for Amateurs and Young Students in Electro-Metallurgy. By G. E. Bonney. London: Whittaker & Co.

THE FERRANTI ELECTRICITY METERS.

THE Ferranti meter, which we illustrate in Fig. 1, is a sort of "nonpolar," or "unipolar," or "one turn" motor. Ferranti, Faure, and others have converted the rotating conductor of the physics text-books into a commercial meter. Messrs. Ferranti have been indefatigable in attacking the difficulties of the apparatus. The essential principle of the meter is the measurement of the rotation of a bath of mercury, through which the current passes from the periphery to the centre after energising a magnetic field, the lines of force of which are at right angles to the radial direction of the current in the mercury. The speed of rotation is proportional to the current, and the movement is transmitted to the register by a fan which is mounted on a light spindle and immersed in the bath. The registering of the meters is as simple as their mechanism. The faces are marked with six dials—units, tens, hundreds, &c.—and the amount registered on these when divided by the constant stated in the instructions will give the number of Board of Trade units consumed. An important feature of the Ferranti meter is the extremely small power needed to work it, and the consequent absence of any appreciable drop in volts. There is only one moving part, and this is perfectly enclosed in a metal case, entirely outside the range of the defects to which a more open form must sooner or later be subject. It is unaffected by external influences; indeed, the correctness of the record is not impaired (as would be the case in some other direct-current forms) by a magnet being placed near it, as might be done by a dishonest consumer.

To overcome the initial friction an auxiliary shunt coil is provided, and is shown in Fig. 1 over the letter N. A resistance placed at the bottom of the case is in series with this. If the shunt current were strong enough, the meter would, of course, slowly revolve, but it is arranged so as to be just too weak to do this. A very small current through the main coils will, therefore, start the meter, whose readings are then proportional to the current. Figs. 2 and 3 are diagrams showing the method of ascertaning the constant of each instrument.

The following tests show the accuracy of the instruments:—Forty ampere alternate current mercury meter, shunted; started with three ampere; mean constant, 7·56 over twenty-fold range; variation—above 1·85 per cent., below 2·12 per cent. One hundred ampere direct current meter; starts with five amperes; mean constant, 2·838 over fifty-range; variation—above 1·3 per cent., below ·99 per cent. Ten ampere continuous current mercury meter, unshunted; started with two amperes; mean constant, 23·56 over twenty-fold range; variation—above 3·98 per cent., below 2·37 per cent.

THE AMERICAN NATIONAL ELECTRIC LIGHT ASSOCIATION.

(*From our New York Correspondent.*)

THE last meeting of this Association was held at Providence, Rhode Island. The city of Providence is very favourably situated for the holding of a convention of this character, being on the direct line of travel between New York and Boston, 175 miles from the former and fifty miles from the latter. In point of numbers it was the largest gathering of the kind yet held, there being over 500 members and guests present. The proceedings were of unusual interest to the electrical profession at large by reason of its having been the occasion for the celebration of the decennial of the commercial application of electricity for lighting. The first session was held on the morning of February 17th. After introducing Mayor Smith, who officially welcomed the Association to the city, President Perry delivered his annual address, which was devoted to a general review of the past history of electrical development. The first business was the report of Chairman Brown on the copper tariff, who reported that by the McKinley Bill the duty on copper had been reduced to 20 per cent. of the former rate, and that the object of the Committee having therefore been accomplished, he asked for the formal discharge of the Committee, which was ordered.

A paper was then read by Mr. W. H. Markland, of the Pennsylvania Railroad, on "Electric Lighting as Applied to Steam Railroads." He said that the Pennsylvania Company had introduced electric lighting at its shops in Altoona in 1881, which was followed in 1885 by the installation of a plant for lighting the station sheds at the same place. This led to the consideration of the question whether the illumination of the yards by electricity could be successfully carried out with a view to reducing the damages arising from the breakage of cars and contents caused by handling the cars during the night. The problem was different from street lighting, as a brilliant light was not so necessary as even distribution. To accomplish this end the lamps in the Altoona yard were placed on 65ft. poles set 8ft. in the ground, so located as to illuminate switches and cross-overs where the yards were narrow. Where yards were wide and long the lamps were placed about 600ft. apart, a row on one side of the yard and a row in a broad alley that was wisely left between tracks near the opposite side of the yards, the lights of the two rows being zig-zagged to prevent shadows and better diffuse the light. This plan does not make a brilliant light at any one point, it being possible, but difficult, to read fine print. The result was something of a moonlight effect, and very good in practice. A clear globe was found objectionable on account of the shadows thrown by the side arms. A lower-half ground globe was found preferable, it being better to lose a little light than to have shadows. This system enabled the car inspectors to perform their duties more satisfactorily, and there was a decrease in the amount of pilferage from the cars, while the breakage of cars and contents was but little in excess of that which occurred in the daytime. The arc lights were of great assistance in shifting cars, as the trainmen are enabled to see the tracks and the position of cars nearly as well at night as by day on account of the light shining on the rails. Also in coupling and dropping cars the men are able to gauge the distances with sufficient accuracy to avoid jar or danger. The switchmen in the towers are also able to tell when a car passes over the switch. Experience has proved that the arc lamp is much superior to the incandescent for shed lighting. With incandescents the necessary volume of light is costly to maintain, and the bulbs soon become dirty from steam and smoke, or require considerable labour to keep clean. The arc lamp is very satisfactory for freight transfer stations, as the men are enabled to see the marks readily, while the foreman can keep watch of his men. One 2,000 nominal candle-power arc lamp to about 1,500 square feet of floor space will generally suffice for a freight transfer station where the lamps are zig-zagged. Where stations are narrow more light per square foot should be allowed. On a platform 10ft. wide one light every 60ft. gives good illumination. The author doubted if the arc lamp could compete with gas so far as cost was concerned, yet, considering the saving in labour and from pilferage, he believed electric lights more than paid for themselves. He believed also that the men worked much more cheerfully and with better results where the light was bright and cheerful. In the new Altoona shops of the company 100,000ft. of floor space is lighted exclusively by electricity, not a foot of gas pipe being run in the buildings. All the travelling cranes are also operated by electricity.

A paper on "Distribution of Steam from a Central Station," by Mr. F. H. Prentiss, was read by Judge Armstrong in the absence of the author. It was devoted to the problem of the utilisation of exhaust steam for heating purposes by underground pipes leading from electric light stations. From the paper and discussion it appeared that this practice had proved financially successful in many instances.

The morning session on February 18th was devoted exclusively to memorial exercises in commemoration of electrical advances during the past decade. During the afternoon session Dr. Louis Bell, Chairman of the Committee, submitted a preliminary report on "Rating the Candle-power of Incandescent Lamps." The simplest method of classification the Committee believed to be was by the watts consumed; the actual power for which the consumer pays, but with a specification as to candle power to limit the efficiency of the lamp to a practical value—that is, a value that will not, on the one hand, produce an inordinate waste of energy, or, on the other hand, force the lamp far above its proper candle-power, and consequently burn it out rapidly. The Committee was emphatically of the opinion that the mean horizontal candle-power should be specified, taking the average of the horizontal illumination in all azimuths. The largest variation from this standard should not exceed 1 candle-power on either side of 16. Without specifying the efficiency, the Committee suggested that a lamp giving over 15 and not over 17 mean horizontal candle-power on a consumption of less than 60 and not less than 55 watts represents the average conditions of central station practice better than any other type of lamp that could be readily found. Several difficulties are encountered in determining the mean horizontal candle-power upon which the standard lamp is to be based. There is, however, one way of determining it—that is, by spinning the lamp about an axis as it is being tested. If a lamp be mounted in a rotating socket and spun rapidly about its own axis, the mean horizontal candle-power can be obtained at once if the velocity of rotation rises to about

Digitized by Google

300 or 400 turns per minute. This process is used in at least one lamp factory with uniform and unvaried success.

A paper was afterwards read by Professor Elihu Thomson, on "The Electric Arc and its Use in Lighting." In the early years of the growth of arc lighting, said the author, the effects obtained were not of the best. Unsteadiness was the rule, and it required much persistent effort to discover the causes and find the remedy. The prominent defects were, and are still, hissing, sputtering, flaming, and general unsteadiness. Hissing or frying comes, of course, with too short an arc, and may be connected with too vigorous vaporisation. They may also be due to a carbon of too coarse grain. Sputtering may arise from impurities in the carbons, and flaming from too long arcs from impure carbons, or from carbons insufficiently baked and containing unexpelled gases. Running an arc at a length between the long arc condition and the short arc condition may cause great unsteadiness of light. There is, in fact, a critical point in the length below which there is a considerable fall of luminosity and a drop of nearly one-third of potential. As an arc lengthens by consumption of its carbons beginning below this critical point, great unsteadiness will be manifest on arriving at the critical state, and a little longer arc brings about a sudden and marked increase of potential, of illumination, and of steadiness. Any observer may easily detect these conditions without special effort. Another important matter in relation to carbons is that the size of section or diameter must be proportioned to the current used. Where attempts have been made to prolong the hours of burning of a carbon by enlarging its diameter beyond certain limits, they have resulted in injury to the character and distribution of the light. Large diameters of carbon may burn too blunt to let the light out between them. Likewise, where attempts have been made to prolong the hours of use by employing a harder or denser carbon than before, it has frequently been found that a sacrifice of light has been incurred, rendering the results much less satisfactory. The fall of resistance with increase of current has an important bearing on the construction of dynamos for arc lighting and the running of lamps on constant potential or incandescent circuits.

The remainder of the afternoon session was devoted to the hearing and consideration of the Report of the Committee on Legislation.

The morning session on February 19th was opened with the reading of a paper by Mr. Caryl D. Haskins descriptive of the "Ferranti System" as installed in London. It was confined chiefly to the machinery used at the earlier stages of the work, the author having severed his connection with Mr. Ferranti some time since.

A paper was afterwards read by Mr. T. Carpenter Smith, on "The Distribution and Care of Alternating Currents," in which he said that the majority of accidents which have occurred from overhead wires have been due to poor construction.

During the afternoon and closing session of the convention, an address was delivered by Mr. Edward Weston, "On Electrical Measuring Instruments, and their Methods of Use and Care." The following officers were elected to serve for the ensuing term:—President, C. R. Huntley, Buffalo, N.Y.; first Vice-President, James I. Ayer, St. Louis, Mo.; second Vice-President, M. J. Francisco, Rutland, Vt. It was voted that the August meeting be held in Montreal, Canada, the exact date to be fixed by the Executive Committee. In accordance with the practice at the more recent of the preceding conventions, an electrical exhibition was established in a separate hall, at which all descriptions of electrical machinery and supplies were exhibited.

THE PHYSICAL SOCIETY.

At a meeting of this Society, on the 27th ult., Professor W. E. Ayrton, F.R.S., being in the chair, a paper, entitled "Proof of the Generality of Certain Formulæ Published for a Special Case by Mr. Blakesley: Tests of a Transformer," was read by Professor W. E. Ayrton, F.R.S., and Mr. J. F. Taylor.

The authors said that in 1888 Mr. Blakesley published a number of formulæ relating to the measurement of power, &c., in alternating current circuits by means of electro-dynamometers, one of which had its two coils independent and placed in different circuits. These formulæ were deduced on certain assumptions, the chief ones being that the currents and magnetisations varied harmonically, and that the magnetic stress in the iron was proportional to the ampere turns. The present paper shows that the above assumptions are not necessary to the truth of the resulting formulæ. To take the case of a transformer, let alternating current ammeters be placed in the primary and secondary circuits, and a direct reading "split dynamometer" have a coil in each circuit. Let D_p, D_s, and D_{ps} be the respective readings of these instruments, then whatever be the law of variation of the currents,

$$D_p = \sqrt{\frac{1}{T}\int_0^T A_p^2\,dt}$$

$$D_s = \sqrt{\frac{1}{T}\int_0^T A_s^2\,dt}$$

$$\text{and } D_{ps} = \sqrt{\frac{1}{T}\int_0^T A_p A_s\,dt}$$

where A_p and A_s are the values of the primary and secondary currents at any instant, and T the time of one complete alternation.

If i be the total induction in the core, P and S the numbers of turns of wire on the primary and secondary respectively, V_p and V_s the terminal pressures, p the resistance of the primary coil, and s the resistance of the whole secondary circuit, then the following equations hold at any instant:—

$$V_p = pA_p + P\frac{di}{dt}$$

$$\frac{di}{dt} = \frac{s}{S}A_s$$

Therefore $V_p = pA_p + \frac{P}{S}sA_s$.

Multiplying both sides by A_p we get $A_pV_p = pA_p^2 + \frac{P}{S}sA_pA_s$, and integrating from $t = 0$ to $t = T$, and taking the mean—

$$\frac{1}{T}\int_0^T A_pV_p\,dt = \frac{p}{T}\int_0^T A_p^2dt + \frac{P}{S}\frac{s}{T}\int_0^T A_pA_s dt;$$

or watts in primary $= pD_p^2 + \frac{P}{S}sD_{ps}$, quite independent of the laws of variation of A and V.

The power lost in heating the iron core was also shown to be $s\left(\frac{P}{S}D_{ps} - D_p^2\right)$.

Other formulæ, such as that given by Mr. Blakesley expressing the primary volts in terms of the dynamometer readings, are shown to be true generally.

On the subject of transformer magnetisations, the authors state that it is desirable not to speak merely of the ampere turns, but also of the self-induction, for they have reason to believe that the magnetising value of an ampere turn varies. Defining the self-induction of the secondary by the equation $L_s = \frac{dN}{dA_s}$, N being the total flux through the secondary, they show geometrically (assuming harmonic variations) that if $L\rho$ diminishes, the efficiency increases, and at the same time the phase angle θ between the primary and secondary currents, and the magnetic lag ϕ, decrease. On comparing this theoretical deduction with the results of experiment they find a good agreement, as will be seen from the following table:—

Frequency.	Efficiency.	$L\rho$	θ	ϕ
160	96·3 %	·0017	113°	0° 24′
160	92 %	·0368	169°	18° 24′
160	85·4 %	·1241	174·6°	45° 36′

Similar results were obtained in different sets of experiments. It was also noticed that as the secondary current is increased, the efficiency rises to a maximum, and then diminishes, whilst $L\rho$, θ, and ϕ diminish and then rise again; the current which gives the maximum efficiency coinciding almost exactly with that which gives minimum values to $L\rho$, θ, and ϕ. The methods employed in making the tests are described in the paper, and the formulæ used in working out the results are there demonstrated. Amongst the facts deducible from the experiments are the following:—

1. With constant frequency, the ratios $\frac{V_s}{V_p}$ and $\frac{D_s}{D_p}$ increase as the primary volts rise.

2. With frequency constant, and primary volts constant, $\frac{V_s}{V_p}$ decreases and $\frac{D_s}{D_p}$ increases as the secondary current increases.

3. With constant secondary current, $L\rho$ decreases as the primary volts are increased.

4. With small constant secondary currents the efficiency diminishes as the frequency increases.

5. For large secondary currents the efficiency is approximately independent of the frequency.

6. Shunting the secondary with a condenser increases the efficiency.

Afterwards a paper, entitled "Further Contributions to Dynamometry," was read by Mr. T. H. Blakesley, M.A. The object of Mr. Blakesley's paper was in the first place to show what sort of physical quantities could be advantageously evaluated by using electro-dynamometers of two coils of low resistance in circuits conveying electric currents. The meaning of a dynamometer reading was explained to be the mean value of the product of two currents, either steady, or undergoing any periodic variations with sufficient rapidity. In mathematical language, such an instrument measured $\frac{1}{T}\int_0^T C_1C_2\,dt$, where C_1 and C_2 were the instantaneous values of the currents in the two coils, including, of course, the common case where these currents are identical. Any physical quantity whose value was such a product C_1C_2, multiplied into something which was independent of the time, and which, therefore, on integration came outside the integrator, was well adapted to have its mean value given by such instruments. Power was such a quantity, being merely (current)^2 × resistance. The square of an e.m.f. was another such quantity, but he did not wish to restrict the method to such evaluations. It follows that any quantity whose instantaneous value can be expressed by terms each quadratic in current, and whose other factor was independent of time, could have its mean value expressed in dynamometer readings. In addition, the particular place and mode of coupling of the dynamometers was indicated by the instantaneous equation, as well as the factor to be applied to each reading. Thus the equations are made to indicate the practical arrangement to be adopted, and the use to be made of the observations in each case.

Examples were given for the cases of transformers in series and parallel, and special applications of the method were suggested in the measurement of the power employed in such diverse apparatus as voltameters subject to direct or variable currents of any sort, welding machines, parallel generators, tuning fork circuits, vacuum discharges, and imperfect condensers. For parallel generators the power of each could be separately estimated, and in the case of electric welders the power employed in the welding circuit was shown to be measurable without introducing any resistance whatever into that circuit.

In the discussion following the paper, Mr. J. Swinburne said the author's assumption that there is no back or forward e.m.f. in the primary and secondary circuits of transformers except that due to $\frac{di}{dt}$, where i is the total induction in the core, was unwarrantable, for in all real transformers there was a "drop" due to waste field, and this made the split dynamometer method useless. It makes the full load efficiencies too high, and this, he thought, accounted for the extraordinary results obtained by Professor Ayrton and Mr. Taylor. If a dynamometer be used at all, it should, he said, be used as a wattmeter, as shown in Fig. 1, the moving coil of the dynamometer D consisting of one turn being joined in series with a non-inductive resistance R, and put as a shunt to the primary. The power absorbed by the instrument itself should be then determined by opening the switch. The power given out by the secondary should be measured by the same or a similar instrument, if the secondary be not non-inductive. Any errors due to self-induction in a wattmeter are, he said, equally present when it is called a split dynamometer, and, in addition to this, the wattmeter as a split dynamometer precludes the possibility of measuring power.

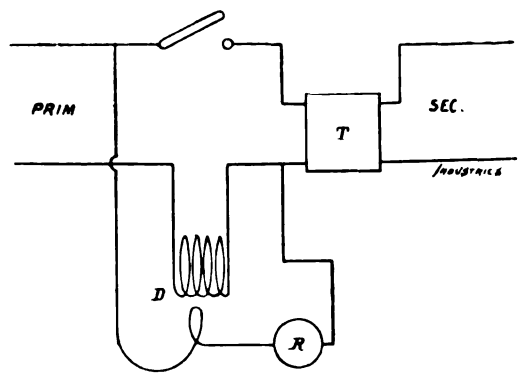

Fig. 1.

Mr. Mordey said the results obtained by Professor Ayrton and Mr. Taylor confirmed experiments he had made himself by an entirely different method, for he found that the losses in the iron decreased considerably as the secondary current increased, and this gave increased efficiency. In his experiments he kept the load constant until the transformer obtained a steady temperature, and then substituted a direct current for the alternating one, varying its strength until the same steady temperature was maintained. The power thus supplied is a measure of the loss in the transformer under the working condition. A 6-kilowatt transformer tested by this method gave a loss of 110 watts at no load, and at full load 205. Of this 205, 176 was accounted for

Digitized by Google

by the loss in the copper coils, leaving only 29 watts as the iron losses at full load. Figures which he quoted from Professor Ayrton and Mr. Taylor's paper showed the same general result.

A "Note on Electrostatic Wattmeters," by Mr. J. Swinburne, and a paper on "Interference with Alternating Currents," by Professor W. E. Ayrton, F.R.S., and Dr. Sumpner, were postponed.

MODERN CHEMISTRY IN ITS RELATION TO SANITATION.

Professor C. M. Tidy delivered his first lecture on the above subject, at the Royal Institution, on the 5th inst. He commenced by quoting the statistics of the Registrar-General for the Administrative County of London for the year 1890, in which it is shown that out of every 1,000 deaths 259 are of infants under one year of age, 425 under the age of five, 594 under twenty, while 156 are of persons whose age is between twenty and forty, and 207 between forty and sixty. Thus, out of every 1,000 persons born only 43 reach the age of sixty and upwards. The death-rate may be likened to a bridge of sixty arches, over which the population passes in a continuous stream, but on which are numerous pitfall and traps, through which many drop to the river below. Less than half succeed in passing the twentieth arch, and of those that struggle on only 43 in every 1,000 who start to cross succeed in reaching the opposite bank. Modern science is endeavouring to place danger signals along the bridge, which may warn the travellers of the pitfalls and evil genii of the road, which are all the more dangerous because invisible. That living organisms accompany disease is a well-ascertained fact, and bacteriologists have proved that special organisms are always present with special diseases. Thus, wool-sorters' disease is always accompanied with the presence of an easily recognised organism, called the *bacillus anthracis*, and the first question to be answered is to decide whether the micro-organism is the cause or the consequence of the disease. If it be the cause, then it must always be present in the early stages of the disease, and must be capable of producing the disease in other individuals. The absence of the bacteria in parts not affected may also be urged as a proof that they are a cause of the disease. It is difficult, however, to demonstrate that the organisms can produce the disease, since it is well known that the lower animals respond differently to human beings in the case of poisons, and that, therefore, the non-production of disease in the case of the injection of micro-organisms into a guinea-pig is not sufficient proof that the organism does not produce the disease. An analogy exists in the case of vegetable poisons, since belladonna leaves have no injurious effect upon rabbits, and morphia is without soporific influence upon pigeons. The lecturer next proceeded to consider the conditions requisite for the growth, development, and activity of the bacteria. These may be shortly summarised as (*a*) good seed; (*b*) good soil; (*c*) proper receptivity. The term zymotic disease, as used by the Registrar-General, indicates that the subject is allied to fermentation, and the facts established by Pasteur and others when working on the formation of alcohol from sugar throw light on the problem of the spread and growth of disease. Alcoholic fermentation is determined by four principal conditions:—(1) The presence of a ferment (yeast); (2) the presence of a body which will ferment (sugar); (3) contact between these two; (4) a temperature between 0° and 50° F. It has been shown that the products of fermentation vary with the temperature, March and October brews, for example, being probably of a uniformly good character from the temperature conditions being similar in these two months.

Probably as the yeast converts sugar into alcohol, so in disease the bacterium converts healthy tissue into subtle chemical poisons, to which the evil effects of the disease may largely be attributed. It is difficult, however, to isolate these chemical poisons, even when a pure cultivation of the bacterium in some nutritive medium has been obtained. Brieger and others have proved that bodies of an alkaloidal nature are produced in many forms of zymotic disease, and the future of preventive and curative medicine depends on further progress in the chemistry of these bacteriological changes. In fermentation, it is well known that the action ceases if the sugar solution be too strong, and when the quantity of alcohol produced exceeds a certain amount, and it seems to be established that similar phenomena are true in the case of disease. In Koch's fluid the active properties are due to the presence of the chemical product or products of the diseased bacilli, and although its action cannot as yet be completely explained, the tuberculin present is death to the bacilli which produced it. Dr. Tidy then proceeded to show that infection, or the atmospheric conveyance of disease from a patient to a healthy person, is due to either a spore, the bacterium itself, or its poison (probably a crystalline body) being present in the air. It has been urged by some that infection could not be caused by a chemical poison acting in this way, owing to most diseases having a latent period before development, but nitro-benzene and mercuric methide are examples of chemical poisons which have well-ascertained latent periods before their toxic action is manifest. A spore may be the common source of infection as many pathogenic organisms have been proved to form spores, which are not only very potent in their action, but are more resistant to change than the bacteria from which they originate, and are known to retain their vitality through long periods of quiescence. A disinfectant to be of any use must be capable of destroying all these three forms of possible infection, and it is obvious that very few substances can be looked upon as fulfilling these requirements of a true disinfectant. Substances used for disinfection must be carefully distinguished from antiseptics, which only retard or prevent the growth of micro-organisms, and deodorisers, which sometimes destroy and sometimes only mask the unpleasant smells which arise from putrefaction. In order to arrive at the best artificial disinfectant it is well to study how nature herself prevents infection. Natural disinfection is brought about by (1) the action of the air; (2) of water; (3) of earth. Air acts in both a mechanical and chemical way. Public opinion on the objections to close rooms, close courts, and houses with no back ventilation, has obtained for each person a given quantity of air at night, but legislation is yet required to ensure the poor against infection arising from over-crowding during the day in the factory and elsewhere. The increase in mortality during cold weather is probably due to persons being more confined to close rooms in winter than in summer. Ozone is a powerful chemical disinfectant present in the air, and although not very abundant, may, by starting the destruction of infection, enable the atmospheric oxygen to bring about a change which it otherwise would be unable to accomplish.

SOCIETY OF CHEMICAL INDUSTRY.

LIVERPOOL SECTION.

At a meeting of this section, held on the 5th inst., Mr. J. Leith read a paper on "The Use of Sulphydrate of Calcium in the Manufacture of Alkali and Bye-Products," in which the author described the method of working his joint patent with Mr. Haddock for the manufacture of sodium carbonate without the production of alkali waste. The author, after pointing out that although the Chance-Claus sulphur recovery process has in a great measure overcome the difficulty the Leblanc manufacturers had of disposing of their waste, yet the bulk and weight of material to be removed is increased by this process, and thus entails greater expense for removal and depositing. The author, after experimenting with the Simpson and Parnell process, in which the waste is distilled with ammonium chloride, finally in conjunction with Mr. Haddock proposed to supersede the distilling operation altogether by using sulphate of soda instead of salt in the carbonating towers, and thus dispensing with the use of ammonia. The operations involved in the modified process are briefly as follows:—Salt cake is made in the ordinary way, and 50 per cent. of the "make" converted into caustic by the Leblanc process, the alkali waste from which is then worked up into a thick cream with water, and transferred into egg-ended upright cylinders arranged in series. Weak sulphuretted hydrogen from the carbonators is then blown through these vessels for some hours, when the calcium sulphide of the waste is converted into soluble calcium sulphydrate thus:—

$$CaS + SH_2 = Ca(SH)_2.$$

In this way nearly the whole of the sulphur in the waste is obtained in solution, the loss of about 8 per cent. of the total sulphur being inevitable in any sulphur recovery process. The solution also contains any alkali which may not have been removed from the waste, and which is finally recovered as soda. The solution in each cylinder is next allowed to settle for some hours, and is then run off into settling tanks, where the last traces of any sediment at all likely to discolour the sulphate of lime, produced at a later stage, is removed. The process so far is essentially one for rendering the lime soluble, and is equally applicable to the sulphides of the other alkaline earths, which may be economically obtained by heating the corresponding sulphate with coal if the new method is to be worked independently of the Leblanc process.

The second part of the process consists in first forming a saturated solution of the remaining 44 per cent. of sulphate of soda, and, after neutralising it by lime or by some of the mother liquor from a later operation, transferring it to a wooden mixing tank, into which the clear sulphydrate solution is also allowed to flow.

The reaction which then takes place is as follows:—

$$Na_2SO_4 + Ca(SH)_2 + 2H_2O = 2NaSH + CaSO_4 2H_2O.$$

The sodium sulphydrate solution thus found is separated from the precipitated calcium sulphate by filtration, and the latter, after pressing and drying, is ready for sale as pearl hardening, while the solution, after the addition of a little mother liquor from the bicarbonate of soda to remove any calcium sulphate which may be present by precipitation, is run off into Solvay's or other ordinary carbonating towers. Lime-kiln gases, as free from oxygen as possible, finally convert the sodium sulphydrate into bicarbonate and sulphuretted hydrogen, the latter being used to form a fresh quantity of calcium sulphydrate, as already described. The decomposition takes place as follows:—

$$2NaSH + 2CO_2 + 2H_2O = 2NaHCO_3 + 2SH_2.$$

The solid bicarbonate is blown on to a filter, freed from mother liquor and wasted to soda ash, while the liquor is concentrated to obtain soda crystals. It will be thus seen that from the raw materials, salt, sulphuric acid, limestoke, coke, and Leblanc waste, the patentees obtain caustic soda, hydrochloric acid, sodium carbonate as ash or crystals, calcium sulphate, lime, and sulphur.

Digitized by Google

The following figures give the quantities of material required and the yield obtained for 1 ton of soda ash manufactured:—

Materials.		*Products.*	
Salt cake	28 cwt.	Soda ash	20 cwt.
Limestone	22 „	Sulphate of lime...	32 „
Coke	3½ „	Sulphur	5 „
Leblanc waste ...	60 „	Lime	15 „
Fuel.....	say 50 „		

The table on page 259 shows the comparative cost of working the new method with that of the Leblanc and ammonia soda process.

It will be seen that the new process claims to utilise all the materials employed, and that there are practically no waste products. The calcium sulphate produced is not only marketable as pearl hardening, but is available as a substitute for china clay in calico finishing, and as plaster of Paris, while the lime-kiln gases, which are wasted as carbonate of lime sludge in the Chance's recovery process, are present in the sodium carbonate produced. As all the stages of the process are wet ones, the loss which necessarily attends all furnacing operations are obviated, and these in the Leblanc process are known to be very high.

MANCHESTER SECTION.

At a meeting held on he 6th inst., Mr. Ivan Levinstein being in the chair, the first paper read was by Mr. Rowland Williams, on "The Relationship Between the Composition of Grey Cloth and Its Liability to Mildew." It was well known, the author said, that grey cloth having starch in its composition was liable to mildew, and there were few manufacturers who had not suffered loss in this respect. He had lately been investigating the subject on thirty samples of cloth representative of the Manchester market. He did not think that the heavy sizing so prevalent of late years was mainly responsible for the increase of mildew cases; in fact, under certain conditions, a pure cloth was attacked by fungoid growths more readily than a heavily sized one. Starchy matters, such as flour and farina, tallow and other fatty substances, china clay, and the chlorides of zinc calcium and magnesium were used in the grey cloth manufacture, especially in the lower grades. Some antiseptic was generally added to the sizing mixture to prevent mildew. Zinc chloride was generally employed, from 1 to 3 per cent. of this salt being added to heavily sized goods. In his experiments the samples of cloth were moistened with water, and subjected, in stoppered bottles, to a heat of 95° Fahr., and the time taken before mildew appeared was noted. The results were recorded in tables, and, in concluding his paper, Mr. Williams said the results, as a whole, showed that there was not so close a relationship between the composition of the cloths and their respective tendencies to become mildewed as might have been expected. He referred more particularly to the ratio between the $ZnCl_2$ and $MgCl_2$ and the total size. The figures, however, certainly showed that $ZnCl_2$ in sufficient quantity exerted a preservative influence on cloth containing large quantities of $MgCl_2$.

Three short papers were afterwards read by Dr. Kneckt, the first being entitled "The Carbonising of Wool in Presence of Silk." By the term carbonising the author meant the destruction of one fibre in a mixture. It was commonly applied to the separation of cotton from wool, whereby the cotton was destroyed and the wool recovered. A method was wanted to separate wool from silk in a mixture; in this case the wool was to be destroyed. He had found that wool was acted on by alkalies, and to a less extent by acids, but found that after all water alone accomplished the object. If the fabric was heated for three hours in high-pressure steam at 130° C. the wool was quite destroyed, and could be rubbed to a powder, leaving the silk unaltered. He showed a piece of fabric with a woollen weft and silk warp where the wool was quite rotted by this process.

The next paper was a note on "The Formation and Direct Fixation of Insoluble Tartrazine on Animal Fibre." Much attention, the author said, had lately been paid to the application of tartrazine to silk dyeing. Hitherto the colours had not been fast, but fast colours were now produced. The colour was prepared by mixing equal quantities of dioxytartaric acid and phenylhydrazine, both dissolved in hydrochloric acid. The solution, which at first was colourless, developed a deep yellow colour on boiling, and in this silk could be dyed a fast yellow.

The third paper was by Dr. Kneckt and Dr. Koechlin, on "The Application of Alizarine in Leather Dyeing." Alizarine, though chiefly used in cotton dyeing, had of late been used for wool, and even for silk, and its superiority for wool dyeing was now recognised in the market. For wool and silk a chromium mordant was used, the temperature of the bath being gradually brought up to 90° C., and maintained for half an hour. In applying alizarine to leather the authors found that the leather would not stand a higher temperature than 50° C., and that the best method of procedure was as follows:—The leather is first brushed over with an alkaline solution of alizarine, and afterwards passed through a bath containing the chromium mordant. By this method a fast dye had been obtained.

Notes.

THE FRENCH NAVY.

The estimates for the French navy for the year 1891 amount to 218,767,702fr. (£8,750,708), of which about 50,000,000fr. (£2,000,000) are reserved for the construction of new vessels or the alteration of existing ones. During the present year there will be in course of building in the Government Dockyards six ironclad battle-ships, two first-class and four second-class cruisers, two torpedo cruisers, two transport avisos, two torpedo avisos, one second-class transport steamer, and one sailing frigate, and of these nearly one-half are expected to be completed during the year. The vessels under construction in French private yards include two ironclad battle-ships, two armoured cruisers, two third-class cruisers, seventeen first-class torpedo boats, two sea-going torpedo boats, and two vedette boats. Of these there are expected to be completed during this year one ironclad battle-ship, two third-class cruisers, and all the torpedo and vedette boats.

ARTIFICIAL RUBIES.

The experiments of MM. Fremy and Verneuil on the artificial production of rubies have been in progress for some years, but it appears from their recent communication to the *Comptes-Rendus* that they have now successfully overcome the difficulties which attend their manufacture, and are obtaining much larger crystals. The artificial rubies have already been employed as pivots in watches, and are said not to be inferior to the natural stones in hardness. The process consists in heating alumina and a trace of potassium bichromate with barium fluoride or a mixture of fluorides of the alkaline earths to a high temperature for several days. Recent progress has been due to the discovery that the addition of a small quantity of potassium carbonate to the mixture, so as to render the fused mass alkaline, facilitates the formation of the crystals. It is believed that the crystals are produced directly from the interaction of the volatile compounds produced, and by employing crucibles of several litres capacity in gas furnaces as much as 3 kilos. of rubies are obtained in a single operation.

CLONMEL WATERWORKS.

The new waterworks at Clonmel, which are to be constructed according to a scheme prepared by Mr. W. H. Radford, will supply a population of 12,000, and the quantity of water required is 225,000 gallons a day. The water will be taken from the Glenmorgan mountain stream about three miles from the town, which affords an ample supply even in the driest summer. There is a watershed of 1,700 acres on the old red sandstone, and there are many constant springs above the intake. The water will be taken from below the surface and roughly screened at the intake through filter baskets. There will be a 7in. supply main, 3,680 yards long, from intake to reservoir, with a fall of 82ft., and delivery of 506,000 gallons a day. The reservoir and filter beds will be placed together on a hill near the town. The filter beds will be 450 yards in area, and divided into four parts for convenient cleansing. The service reservoir will be constructed of concrete, and covered with concrete arching. The capacity of reservoir will be 450,000 gallons, or two days' supply. The 9in. service main from reservoir to town will have a working hydraulic gradient of 1 in 139, and at that gradient it will deliver water 30ft. above the eaves of the highest building. At the hydraulic gradient it will deliver 38,640 gallons an hour; the average hourly consumption being only 9,375 gallons an hour.

THE MINERAL WEALTH OF INDIA.

We sometimes hear of the great possibilities of the industrial resources of China, on account of her vast mineral deposits, but hitherto those of India have been supposed to be confined chiefly to those depending directly or indirectly on agriculture. A book by Captain C. C. Townsend, R.A., of the Indian Ordnance Department, has been published by Thacker & Co., of Bombay, which seems to open up such a boundless vista of possibilities that we feel compelled to look forward to India as the future iron and steel producer of the whole world, and to see it a busy field of industrial enterprise long after the furnaces and factories of Britain shall be black and silent. Captain Townsend does not deal with the precious metals or stones of India, to which already considerable attention is being paid, but confines his attention to the vast deposits of iron ores and of minerals necessary to the iron and steel industry, and he indicates several localities in which all that is wanted to start large establishments could be found within a convenient area. He gives many suggestions which would be found of use to those who may turn their attention to a matter, which, if taken up in earnest, may have a great effect on the future of the industrial world, if Captain Townsend's facts are to be depended upon. He does not pretend to treat the subject in an exhaustive and scientific, but rather in a suggestive and commercial manner, and thus appeals to a wider circle of readers.

THE CONDITION OF MINERS IN HUNGARY.

The number of persons employed in the mines of Hungary is 35,533, of which 29,830 are men, 5,000 boys from twelve to sixteen years of age, and the remainder are women. The wages earned, according to the *Revue Industrielle*, are less in the mineral mines than in the coal mines, the average daily wage earned in coal mines being from 2s. to 2s. 6d., while in the mineral mines it is only 1s. 4½d. to 1s. 6½d. per day. In the mineral mines work is not usually carried on in the night, but in cases where it is done the day is divided into three shifts of eight hours each. In some newly-started mines the hours of labour are from 6 a.m. to 6 p.m., with a stoppage of one, and sometimes two, hours for meals, while in others the number of hours is eight, two shifts being employed. In the coal mines work is usually carried on both night and day by means of a double shift, each shift working twelve hours, with an allowance of two hours for meals. The miners are generally housed in houses built by the mining companies, the rent for the smallest house being £1 per year! Several of the large companies also provide their workpeople with all necessaries at cost price. Mutual help societies exist among the miners. Strikes among the Hungarian workers are fortunately rare, and when such occur, as in 1875, 1880, and 1887, are not of long duration, and have usually been found to have been caused by the incitation of foreign workmen.

THE CENTESIMAL METHOD OF MEASURING ANGLES.

At a congress of makers of surveying instruments, recently held in Bremen, an attempt was made by Dr. Foerster to ascertain to what extent the decimal division of the quadrant was employed by German instrument makers. Inquiries were forwarded to 150 firms, and twenty-two answers have been received. Of this number eight firms make use of the centesimal graduation to a certain extent, as shown in the following table:—

Firms.	Instrument with Decimal Graduation.
3	Less than 10 per cent.
2	More than 10 per cent.
1	More than 20 per cent.
1	More than 50 per cent.

The new graduation appears to be used most extensively in Baden, where, since 1820, it has been employed on the Government surveys. A leading firm of instrument makers in Carlsruhe report that, with the exception of the instruments they make for export, almost all the theodolites they sell are graduated centesimally. One dividing engine is used both for the 360° and 400° divisions. The centesimal division may easily be added to any existing dividing engine, so that there need be no mechanical difficulties to prevent the adoption of the decimal graduation. The explanation of the unpopularity of the centesimal method in this country and in the United States is to be sought rather in the unsatisfactory character of the trigonometrical tables available. All the tables calculated for the centesimal method, such as those of Borda, Hobert, and Plauzoles, are not arranged so clearly as Chambers' tables. The advantages of the new method are urged by Mr. T. G. Gribble, Assoc.M.Inst.C.E., in a work he has recently published on surveying, and the matter is one which certainly deserves the attention of surveyors.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

23rd February, 1891.

3220. W. Rothwell & Co., Ld., & Rothwell ..... Cutting knitting machine needle beds.
3224. Heywood & Holland ... Reciprocating "pegging" machines.
3226. Smyth, S. R. (of the Steel and Iron Company, Ld.) ..... Apparatus connected with the treatment of ores and metals in furnaces.
3231. Claridge, J. W..... Machine for drilling holes of various shapes.
3233. Fairweather, W..... Tilting gear for rolling mill plant.
3235. Begg, W..... Looms.
3238. Hales & Ramsden..... Machine for making corrugated paper.
3240. Williams, W. ..... Apparatus for ventilating mines.
3243. Rothwell, T..... Machines for opening and cleaning cotton.
3244. Higham & Appleton..... Pickers for looms.
3258. Steinmetz, S..... Machines for cleaning, husking, and preparing cereals.
3261. Weiss, O. ..... Petroleum engines.
3268. McGlasson, R. ..... Apparatus for governing and operating marine engines and propellers.
3269. Dunlap, F. W. ..... Mechanical telephones.

24th February, 1891.

3275. Petrie & Petrie ..... Machinery for washing, scouring, and cleansing cotton waste, rags, &c.
3280. Bateman, D. C. ..... Apparatus for grinding the points of wire cards.
3281. Holden, J. ..... Looms.
3285. Green, Green, & Clarthero ..... Rotary engine.
3288. Titus & Werner ..... Feed water purifiers.
3293. Eades, W. T. ..... Tube expanders.
3298. Young, W. ..... Railway signalling and facing point locking apparatus.
3302. Craven, P. P..... Spinning frames.
3316. Galtier, M. H. A..... Recording clinometer.
3322. McFarlane & Reid ..... Self-lubricating sheaves, pulleys, and wheels.
3324. Eddy, A. H. ..... Screw machines.
3325. Thompson, W. P. ..... Metallic railway sleepers (*Sweet*).
3327. Thompson, W. P. ..... Die stocks and dies (*Fletcher & Emmert*).
3329. Spencer, C. M. ..... Screw machines.
3330. Glover, J. ..... Apparatus for excavating.
3333. Hallowell, J. K..... Apparatus for treating ore.
3334. Dinstuhl, G. ..... Steam traps.
3337. Lake, H. H..... Vacuum pumps (*Berrenberg & Nickerson*).
3350. Coffey, B. H..... Gas engine.
3352. Lake, H. H. ..... Vacuum pumps (*Berrenberg & Nickerson*).
3368. Richards, G. B. (of Messrs. Westray, Copeland, & Co., Ld.) Marine and other steam engines.
3371. Mannesmann, M. ..... Apparatus for forming, rolling, and calibrating tubes.
3377. Clark, A. M. ..... Vacuum pump (*Bornholdt & Glatz*).

25th February, 1891.

3391. Atkinson, J. ..... Gas engines.
3396. Martin, E. ..... Filtering machinery.
3413. Lyon, C. W. ..... Apparatus for charging and discharging gas retorts.
3419. Munns, W. H..... Scroll sawing machine (*Laird*).
3420. Munns, W. H..... Car coupling (*Phelps*).
3422. Munns, W. H..... Wrench (*Huntsinger & Marshall*).
3454. Lake, H. H. ..... Apparatus for the manufacture of screw-threaded bolts or pins (*The Russell and Irwin Manufacturing Company*).

26th February, 1891.

3464. Michaud, J..... Rotary printing machines.
3466. Hetherington, J. M. ... Opening and scutching machinery.
3468. Young, J. ..... Machinery for making bobbins.
3503. Anderson, C..... Apparatus for exhausting the products of combustion from locomotives.
3511. Singer & Dombrain..... Apparatus for extraction of liquids from pulverulent materials.
3514. Wilcox, B. ..... Apparatus for condensing steam or vapour (*Fouché*).
3525. Chandler, J. C. ..... Apparatus for purifying gas.
3526. Loveday, Loveday, & Loveday ..... Slide valves of steam engines.

27th February, 1891.

3548. Lyon & Fearn ..... Machines for reeling yarn and thread.
3551. Boult, A. J. ..... Pneumatic ordnance (*Eichbaum*).
3555. Thompson, W. P. ..... Concrete mixing machines (*Hotchkins*).
3564. Bailey & Bailey ..... Sight feed valves for lubricators.
3568. Aimers, J. ..... Valve gear for steam engines.
3574. Hurtley, J..... Machines for balling warps.
3582. Mountain, B. ..... Machinery for rolling metallic rings and for making wire.
3583. Alpe, R. J. ..... Drilling machines.
3585. Phipps, T. ..... Stop valve for gases.
3586. Hill, C. W..... Balance piston arrangement for the valves of high speed engines.
3593. Schönberg, I. ..... Saw sharpening machine.
3599. Tyler & De Vesian..... Locomotive steam engines.
3601. Vanoutryve & Le-paintebr..... Machinery for the manufacture of chenille and like threads.

28th February, 1891.

3628. Postlethwaite, G. R.... Dynamometers.
3631. Wild, J. ..... Steam traps.
3635. Hoyle, E..... Steam engine governor.
3641. Brierley, W..... Taps and valves (*Hoyle*).
3672. Bradley & Crossley ... Igniting and starting apparatus for gas engines.
3682. Wertenbruch, F..... Gas and hydrocarbon engines and the pistons thereof.
3685. Horn, W. W. ..... Hub boring machine (*Bonner*).
3687. Horn, W. W. ..... Engine-reversing gear (*Barnes*).
3688. Whitehead, E. E..... Apparatus for cutting tubes.

ELECTRICITY.

23rd February, 1891.

3239. Raworth, Callender, & Webber ..... Underground conduits.
3262. Gimingham, E. A. (of the Edison and Swan United Electric Light Company, Ld.) Incandescent lamps.
3265. Grandinger, H. F. ..... Process of electro-plating.

24th February, 1891.

3331. Currie, S. C. C. ..... Storage batteries.
3336. Lake, H. H. ..... Electric welding apparatus (*Lemp & Schmidt*).
3349. Dewey, M. W. ..... Electric welding apparatus.
3364. Lake, H. H..... Incandescent lamps (*Nickerson & Berrenberg*).
3383. Kingdon, J. A. ..... Dynamos.

25th February, 1891.

3404. Elliot & Furtado ..... Switches for telephone circuits.
3426. Dowsing, H. J. ..... Brushes and brush holders for electric machines.
3449. Rabbidge, P. ..... Telephones.
3450. Power, W. H. ..... Primary batteries.
3455. Birkin, W. A'C. G. ..... Percussive rock drills.

26th February, 1891.

3495. Dorman & Smith ..... Switches.
3518. Guyard, E. ..... Inking device for telegraphic instruments.
3524. Sanders, R. D. ..... Manufacture of metal tubes by electro-deposition.

27th February, 1891.

3538. Mackie, J. ..... Apparatus for automatic stop motions and analogous applications in spinning, twisting, winding, and other machines.
3553. Thompson, W. P. ..... Conduit electric railways (*Reed*).
3589. Lake, H. H. ..... Electric batteries (*Dowse*).
3592. Whitehead, W..... Alarm apparatus.
3609. Hartmann & Braun ... Electricity meters.

28th February, 1891.

3673. Seibold, A. C. ..... Arc lamps.
3675. Edwards, E. ..... Apparatus for the transmission of messages by direct or alternate currents.

CHEMISTRY.

23rd February, 1891.

3222. Clark & Clark ..... Reducing metallic oxides.
3230. Ascough, J..... Manufacture of borax and soda and other compounds containing sodium or boron or both.
3270. Fischesser, A. ..... Azo colouring matters.

25th February, 1891.

3387. Lapone, H. ..... Manufacture of aluminium from aluminia.
3439. Willcox, B. ..... Azo dyes (*Farbenfabriken vormals Friedrich Bayer & Co.*).

27th February, 1891.

3557. D'Andria, M. N. ..... Manufacture of barium nitrate and strontium nitrate.
3657. Howitt, J. J. ..... Apparatus for the manufacture of carbonates of soda.
3622. Vidal, R. ..... Production and separation of methylamines, ethylamines, phenylamines, and naphthylamines.

MISCELLANEOUS.

24th February, 1891.

3276. Whitaker, R..... Wood screws.
3358. Dvorkovitz, P. ..... Manufacture of gas from fluid hydrocarbons.
3359. Jagenburg, R. ..... Valve packing.

25th February, 1891.

3416. Smethurst, J. ..... Lock nuts and bolts (*Gledhill*).
3444. Horn, W. W. ..... Nut lock (*Barlet*).

26th February, 1891.

3510. Lang & Wigham ..... Process for protecting iron and steel wire against corrosion.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

1237. Mannesmann.
1238. Mannesmann.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Gas Engine Governors.—*C. D. Abel, London. (The Gas Motoren Fabrik Deutz, Köln-Deutz, Germany).*—The governor constructed according to this invention is shown in the annexed illustrations applied to a gas engine of vertical construction. A is the gas valve, the rod of which is connected by a bell-crank lever B to a sliding rod C, opposite which is a rod C^1 pivoted to

a slide D, and having a weighted arm D^1 fixed to it, the slide D having a to and fro motion imparted to it by a link E, connected to the rod F that works the gas slide G of the engine. G^1 is the discharge valve of the engine, closed by a spring and opened during the discharge period by means of a bell-crank lever H H^1, the arm H of which bears with a roller I against a cam J on the countershaft that works the gas slide. The bell-crank lever has a tail with a projecting stud K, and a lever L pivoted to the engine frame, has a hooked end M, which catches over the stud K when the bell-crank lever H H^1 has been moved inwardly by the cam J, in which position it holds the discharge valve open, the lever L being acted upon by a spring N, which tends to hold it in this position. The other end of the lever L is connected by a rod O to the rod of the valve A, so that when the valve is forced open by the action of the parts B C C^1, the lever L is at the same time moved so as to release the stud K, whereupon the discharge valve G will be closed by its spring when permitted to do so by the cam J. From the above description it will be seen that every time the discharge valve is opened by the cam J it will be held open by the catch M until this is withdrawn again on the opening of the gas valve A, so that when this fails to be opened by the device C C^1 of the inertia governor, on the normal speed of the engine being exceeded the discharge valve remains open, allowing the products of combustion to be drawn back again into the cylinder from the discharge pipe, until by the reduction of the speed the inertia governor again causes the gas valve to be opened during the charging stroke, whereupon the discharge valve will close again. Three claims are made.—No 4164. March 17th, 1890. 8*d.*

Hydrocarbon Engines.—*H. A. Stuart, Bletchley, Buckinghamshire, & C. R. Binney, London.*—The invention relates to those engines operated by the explosion of mixtures of combustible vapour, &c. Referring to the accompanying illustrations, Fig. 1 is a sectional side elevation, Fig. 2 an end elevation, and Fig. 3 a cross section of the vaporiser of such an engine of the two-cycle type. The piston A of the cylinder B is connected to the crank-shaft C in the usual manner. At the back of B and communicating with it is the vaporiser D formed with ribs D^1 (Fig. 3), as described in a prior patent No. 15994 of 1890, and with an air valve E. The vaporiser D is surrounded by a casing F provided with a damper F^1. The frame work of the engine contains the hydrocarbon tank G from which the oil is drawn by means of a pump H actuated through a bell-crank lever I, a cam J on a counter-shaft K, and suitable gearing from C, through a spraying nozzle L into D. A suitable valve, placed in the pipe connecting G with H and governed by a governor M, actuated from C (Fig. 2), serves to regulate the supply to H and so control the speed of the engine. The exhaust valve N, communicating with the rear end of B, is actuated through the lever N^1 from a second cam J^1 on the shaft K. Claims: In an engine operated

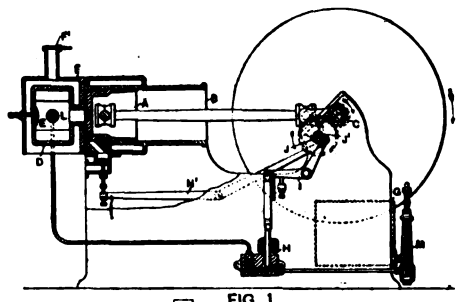

FIG. 1

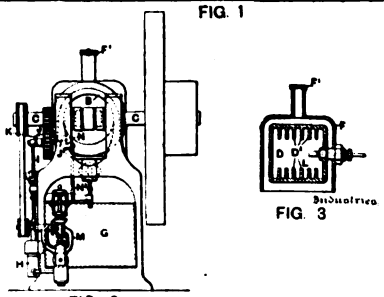

FIG. 3

FIG. 2

by the explosion of hydrocarbon vapour and air—(1) The employment of a vaporiser in direct communication with the working cylinder, which vaporiser is maintained at the requisite degree of heat by the combustion of the combustible mixture therein, and also serving to ignite the combustible charge; (2) forming the mixture of gas and air by introducing the gas or vapour into a charge of air under compression; (3) the combination with a vaporiser of a cover surrounding the same and provided with upper and lower openings; (4) the employment of governing mechanism to operate upon the suction valve of the oil injecting pump in such a manner that, when the engine is running above its normal speed, a reduced supply of oil will be delivered into the vaporising chamber for the purpose described; (5) the manufacture and use of the improved hydrocarbon engine, described and illustrated.—No. 7146. May 8th, 1890. 8*d.*

High-pressure Valve Taps.—*A. W. King, Eastbourne, Sussex.*—Sliding in a straight portion of the valve body is a tightly fitting tube, to one end of which is connected, by means of suitable webbing, the valve proper, which, by moving the tube carrying it longitudinally in the body of the valve, can be forced against a suitable seating in the said body. This seating is formed separately, and has projecting from its outer periphery a flange, which is firmly held between flanges formed on the two parts of the valve body. These parts are suitably bolted together, so securing the valve seating. A flange, slightly smaller than the interior of the valve body, projects from the underside of the valve seating, between which and the former the reduced end of the tube carrying the valve proper slides. This tube is moved longitudinally by means of a rod connected thereto and passing through an inclined slot formed across the valve body. Thus, by moving this rod to the right or the left, the tube will be moved in one or the other direction by the rod following the direction of the slot. Claims: (1) In a valve cock an inclined slot in the outer casing to impart a vertical movement to the valve by rotating a handle projecting through said slot, and connected to the valve; (2) in combination with a valve cock, a cushion, consisting of an indiarubber ball, containing air confined therein, the ball being situated in the waterway to avoid concussion in the pipes.—No. 2973. February 25th, 1890. 6*d.*

Crushing Machines.—*D. Brennan, Bayonne, New Jersey State, U.S.A.*—The machine embraced by this invention is for the purpose of crushing ores and such like material by means of two adjustable rollers, and is shown in the annexed illustrations, of which Fig. 1 is a sectional side elevation, Fig. 2 a plan, and Fig. 3 an end elevation. On the hollow bed A are bolted the fixed heads B carrying suitable bearings for securing the spindle of the roller C driven from D. Opposite C is the adjustable roll C^1 running in bearings in heads B adapted to slide on A, but held thereon by bolts E sliding in slots A^1 in A. The heads B B

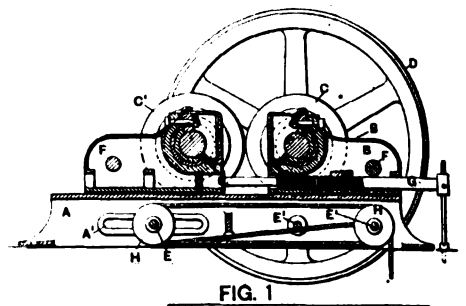

FIG. 1

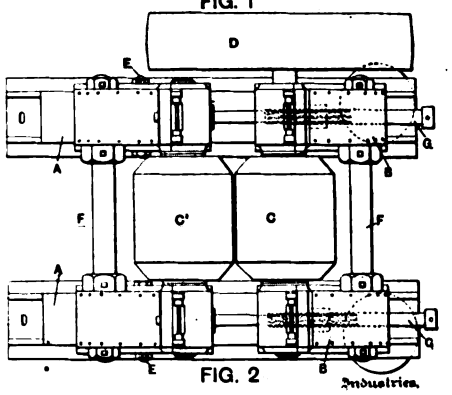

FIG. 2

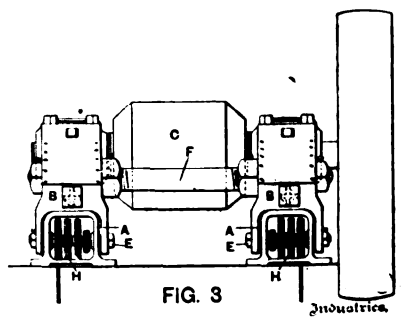

FIG. 3

are bolted together by bolts F. The space between the two rollers can be increased or diminished to suit the fineness to which the ores and other material are to be ground, by means of screwed adjusting rods G, working through the lower portions of the heads B. Carried on the bolts E E in B B are sheaves H, around which pass suitable wire or other ropes, having one end fixed to the bolt E^1, and the other end carrying a suitable rod (not shown). The lower end of this rod is flanged, and supports a helical spring, upon which are placed suitable weights, the number of these, of course, depending upon the pressure it is desired to put on the rollers. The bearings in the heads B B are of a form substantially as shown in Fig. 1, suitable passages being made therein to allow the waste oil to pass from the backs of the bearings on to the surface of A. Eleven claims are made.—No. 20531. December 16th, 1890. 8*d.*

Brick Machines.—*J. & R. T. Dixon, Horwich, near Bolton.*—The object of the present invention is to close the top of the trough after the shale is fed into it, and before the ram enters, so preventing the escape of the shale. For this purpose a plate arranged to work in slides on the top of the receiving trough is used, such plate being held in a parallel position with the back ram by the slides and operated by a rocking shaft having two arms and coupling links connected to the plate, the rocking shaft receiving its motion either from the fly wheel or from the back ram shaft which has two projections fastened to it, so as to come in contact with a cam on the rocking shaft. The motion of the plate closes the opening into the trough after the ram has received its full charge of shale or clay, so converting the trough into a box, and, this remaining shut, the shale is pressed into the mould. The slide then moves back and the trough receives a new charge. Claims: (1) In brick machines the use of a slide for closing and opening the trough or feed box as and for the purpose described; (2) the combination of parts as described.—No. 5188. April 3rd, 1890. 6*d.*

Railway Chairs.—*G. W. & R. B. Rittersbach, both of Philadelphia, Pennsylvania, U.S.A.*—Two bed-plates of a suitable length, width, and thickness are secured to the opposite ends of a tie. These plates have formed on each end of them upwardly extending hollow ears, between which ears the rail is placed. Suitable cheek pieces are then passed through these ears so that the inner ends thereof press upon the lower flange of the rail, so securing it. Suitable holes are formed in the outer ends of these cheek pieces and in the bed-plates, so that when the cheek pieces have been placed in position the holes coincide, so allowing the securing spikes to be driven through them into the tie. Claims: (1) A railway chair, consisting of a bed-plate with ears and cheek pieces horizontally entering said ears, the plate and pieces

Digitized by Google

having openings and slots for securing devices as described; (2) the bed-plate and cheek piece formed and secured as described; (3) a bed-plate formed of wrought metal with ears pressed out of said plate to form apertures with the surface of the plate, in combination with cheek pieces adapted to be inserted horizontally, said plate and piece having openings for the reception of securing spikes; (4) the arrangement as described.—No. 18632. November 18th, 1890. 6*d*.

LET-OFF MECHANISM OF LOOMS.—*J. & R. Lindsay, both of Dundee, N.B.*—The mechanism referred to in this patent is for the purpose of rendering the tension of the warps as uniform as possible, and is shown applied in the accompanying illustrations, of which Fig. 1 is a side elevation and Fig. 2 a plan. The weighted lever A pivoted at A¹ carries a hinged lever B, which,

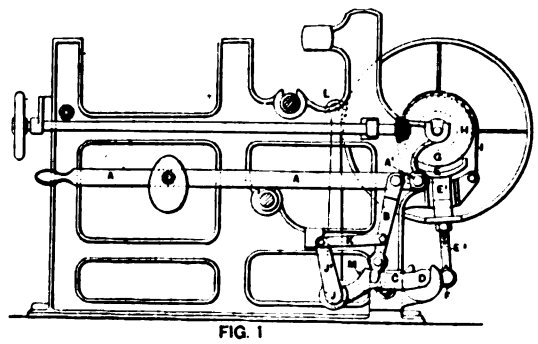

FIG. 1

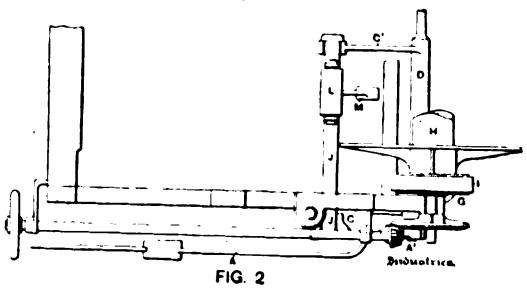

FIG. 2

operating upon the radial arm C of a spindle D, transmits the pressure to the frictional block E, which is supported by a block E¹ and rod E², the latter being pivoted at F to a second radial arm on D. The block E presses against a drag head G fixed on the warp beam H, and so causes it to be retarded in its motion by the frictional band I. Revolving in bearings on the end of the arm C and a second radial lever C¹ on D is a shaft J connected by radial arm J¹ and link K to B. Formed on J are two radial arms carrying a roller L adapted to be pressed against the yarn beam by weight M. It will thus be seen that as the yarn beam diminishes in size the shaft J will be gradually revolved, so causing, through arm J¹ and link K, B to operate on C nearer its fulcrum, thus diminishing the frictional pressure of block E. Claims: In let-off mechanism of looms for weaving, applying to the warp beam frictional apparatus in which the pressure is transmitted from one or more weighted levers through one or more strut links acting on one or more curved levers, the said strut link or links being moved nearer the fulcrum of the curved lever or levers in proportion as the diameter of the yarn on the warp beam diminishes by a lever or levers which keeps in contact with the yarn on the beam, the parts being arranged, combined, and operating substantially in the manner described.—No. 4334. March 20th, 1890. 6*d*.

APPARATUS FOR INSULATING ELECTRIC CONDUCTORS.—*S. Pitt, Sutton, Surrey.* (*J. B. Atherton, New York, U.S.A.*)—The apparatus embraced by this invention is for the purpose of winding one or more narrow strips of insulating material around a wire of any suitable diameter. In the accompanying illustrations

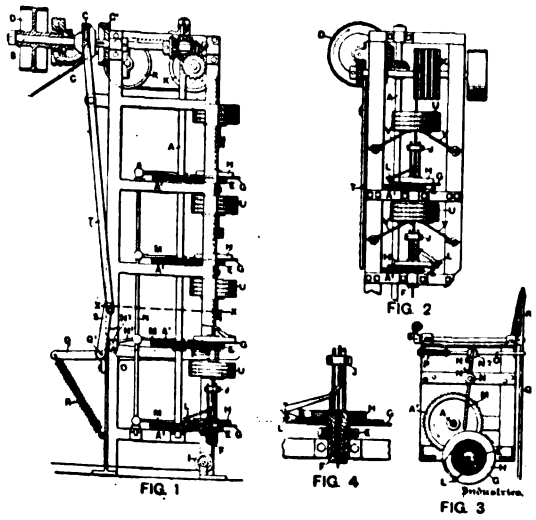

FIG. 1

FIG. 2

FIG. 4

FIG. 3

Fig. 1 is a side elevation, Fig. 2 a front elevation of the upper part of Fig. 1, Fig. 3 a sectional plan on line X X, and Fig. 4 a sectional detail of such a machine. In a suitable framework runs a vertical shaft A geared by intermediate gearing with the driving shaft B, on which slides the frictional clutch block C, capable of either engaging with the sleeve of the loose driving pulley D or being inserted in the stationary frictional block C¹. At suitable intervals along A are fixed gear wheels A¹, each of which gears with a pinion E on a short hollow shaft F mounted in bearings in the front cross-bars of the framework. Each of these shafts carries a plate G, on which are fixed the bobbins H of insulating strips. The wire to be covered is fed in around I, passes up through the shafts F, receiving a covering of paper from each of the bobbins H, which is smoothed by means of die blocks J supported on G, and is taken up by rollers K K driven by means of a worm and worm-wheel from B. The insulating material is fed from the outside of the bobbin, and passes around a knock-out latch L, so preventing the latter falling. Upon the breakage of the ribbon this latch falls, and its end is thrown into the path of a rod M projecting from a vertical shaft N. The momentum of the plate G causes the latch L to partially turn the shaft N, and by means of a rod N¹ working between ears N² on a horizontal sliding rod O, this rod is moved endwise against the pressure of its spring P and the end of the rod O, which dogs the hand-lever Q, carried by a rock shaft Q¹ is withdrawn from the lever, and by the action of a spiral spring R, the rear end of the lever is drawn down, the rock shaft turned, and by means of a crank S thereon the lever T is thrown outwardly, and the clutch C is pressed against the clutch surface C¹ and the motion of the machine immediately arrested. Suitable spare bobbins U are supported on arms V above G, and may be applied to the latter when the other bobbins are exhausted. The inventor also describes a modification of the above in which the shafts F are placed side by side, and not one above the other. Seven claims are made.—No. 911. January 17th, 1890. 8*d*

FLUID PRESSURE BRAKE MECHANISM.—*R. Battye, Sydney, New South Wales, Australia.*—The invention relates to mechanism used for controlling the action of railway and tramway brakes, and is so constructed as to be extremely sensitive to the smallest appreciable reduction of pressure in the brake-pipe, so rendering the application of the brake practically instantaneous. It further consists of the introduction between the brake-pipe and piston chamber of a controlling valve, and the use of a piston and quadruple valve in combination therewith. Referring to the accompanying illustrations, of which Fig. 1 is a sectional elevation, and Fig. 2 a sectional plan on line X X, A is the upper

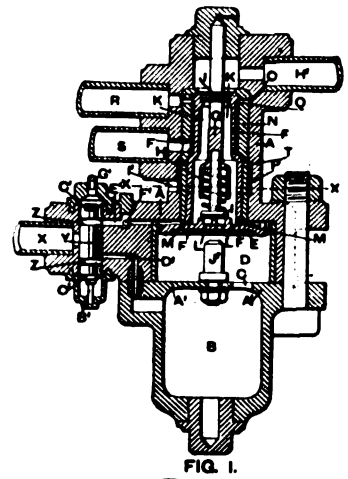

FIG. 1.

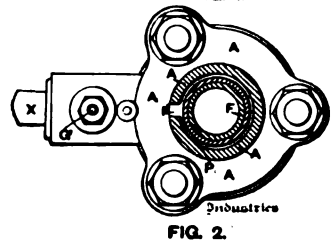

FIG. 2.

casing and A¹ the lower casing, B drip cup, C port in B communicating with piston chamber D, E cup-headed piston, F quadruple cylindrical slide valve, G centre valve spindle cupped to receive spring H of the central valve I, J screw plug attached to G and having perforations K, L port in E, M perforations in F, N O P annular grooves around F, Q slots leading from N to O, and also brake pressure and release cylinder pipes R and S, T slots leading to P; X train pipe connection, Y chamber of controlling valve Z operated by spring B¹ and having diaphragms C¹, D¹ passage leading from Y to B, E¹ passage from Y to M, F¹ back pressure valve in E¹, G¹ pipe connecting diaphragm chamber with auxiliary reservoir, H¹ pipe to auxiliary reservoir, I¹ exhaust port in A. The manner of operation is as follows:—Air being introduced at X, passes through Y along D¹ into B, thence through C into D, and pressing E upwards opens I, and passes through L into F, thence through K into H¹, which has the effect of introducing the pressure to the reverse side of E through perforations M. The downward movement of E unseats the valves formed by shoulders on F, causing Q to open, establishing communication with Q, and thence by R, to brake pressure cylinder. By the excess of pressure in the train pipe E and F are forced to their position of rest, and communication is opened between R Q O and S, thus putting off the brake by using the air from the brake pressure cylinder. The air so used will remain in the brake release cylinder until a downward movement is given to E and F, when such movement will establish communication between S N T I' and I¹, thus discharging the air from the brake release valve into the open air. The action of the controlling valve is as follows: When the pressure in the auxiliary valve has diminished sufficiently to allow B¹ to operate, C¹ is moved so as to open E¹ and close D¹, which will have the effect of introducing the air along E¹ through M, thence through K to H¹, instead of by D¹ to B, through C to D, and as E is then resting on a stud J¹ it is obvious that communication is also established with R. The inventor also describes a modification of the above. Five claims are made.—No. 16283. October 13th, 1890. 8*d*.

STEAM BOILERS.—*J. Kirkaldy, London.*—The steam boiler is made of a vertical cylindrical form with a dome top, and furnished at the bottom with an inner cylindrical fire-box, the top of which is also domed and has an outlet passage extending sidewise from it and carried to an opening formed through the cylindrical shell of the boiler. Above this opening another large opening is formed through the shell, and a corresponding large opening on the opposite side is made. Outside each of these openings is secured a flat tube plate, each tube plate flanged and shaped around its edges in such a manner that it may be secured to the exterior of the boiler shell. A number of tubes are passed across the interior of the boiler from one tube plate to the other. The products of combustion from the fire are led from the side outlet from the fire-box to one end of the tubes by a sheet metal casing secured to the exterior of the shell, and, passing through the tubes, enters a second sheet metal casing covering the other end of the tubes, and from which a chimney passes. In two claims the inventor embraces the construction of steam boilers substantially as described.—No. 5278. April 5th, 1890. 6*d*.

SINGLE-ACTING ENGINES.—*G. Richards, Altrincham, Cheshire.*—In the annexed illustrations, of which Fig. 1 is a front sectional elevation and Fig. 2 an end sectional elevation, is shown an

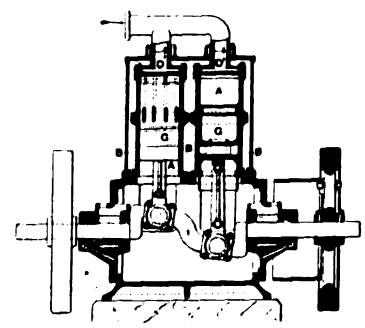

FIG. 1.

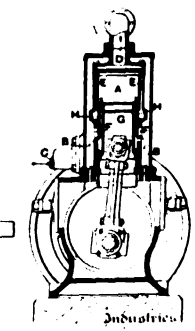

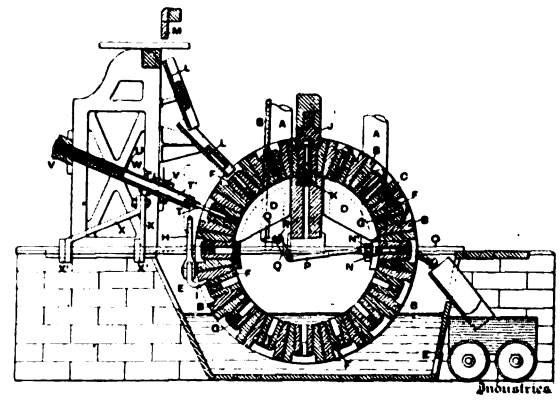

FIG. 2.

engine embracing the principle of this invention, both cylinders being in this case supplied with steam at the same pressure. The cylinders A are surrounded with a casing B, the interior of which is connected with the exhaust pipe C. The cylinder covers are made hollow and are connected with the supply pipes D, and small passages E in the cylinder casing pass therefrom to ports at about the centre of the cylinders. Similar exhaust ports F are formed in the cylinders below the supply ports, but not in the same vertical plane. Formed in the piston G are passages H connecting the upper end of the piston to ports at about the centre thereof. The crank pin I is set at an excessive angle, as shown, in order to rotate the pistons sufficiently to bring the ports therein successively opposite the supply and exhaust ports. The inventor also describes a compound engine constructed in a similar manner. Claims: (1) In a single-acting engine with one or more cylinders having the steam admitted and exhausted by a partially rotating piston, the method of arranging and constructing the ports for admitting and exhausting the steam for the purpose of reducing the angularity of the crank as described; (2) in a compound single-acting engine provided with high and low pressure cylinders arranged with two or more steam cylinders and having the steam admitted and exhausted by a partially rotating piston, the method of arranging and constructing the ports for the purpose of reducing the angularity of the crank.—No. 21002. December 24th, 1890. 11*d*.

RIVET-MAKING MACHINES.—*H. Fletcher, Greenwich, & T. C. McFarlane, Newcastle-on-Tyne.*—The accompanying side sectional elevation is that of a machine constructed according to this invention. A are columns for supporting the driving mechanism of the machine. B are wedge-shaped blocks connected together at the sides by pairs of links C to form a ring that is supported upon a saddle D and dips into water in a trough E. Each block B carries a die F fitted with a sliding stopper G that normally forms the bottom of the die. H is a rod that is reciprocated from the

driving mechanism of the machine and carries a finger or projection I, by which the drum is intermittently rotated. L are pivoted shoots, down which metal blanks cut by a movable shear blade M from a metal rod fall in regular succession into the dies as they are brought one by one below the lower edge of the lower shoot. The rivet blank is passed between the heading tool J and a bridge-shaped anvil K. N is a horizontal pusher, which by acting against the inner end of each stopper as it comes into a horizontal position, forces the stopper from the inner to the outer end of its corresponding die and thereby ejects the finished rivet from the die. The pusher N is carried by a cross-bar N¹ arranged to be reciprocated on guide rods O by a link P, crank arms Q, shaft R, and rods S from the driving mechanism of the machine. Each of the stoppers G has a groove formed in it in which is placed a spring which normally holds it in the die. The stoppers G are pushed back to the inner end of the dies after delivering a finished rivet by means of the pusher T carried by a rod T¹ held in a tube U sliding in guides V. This tube is reciprocated by the bifurcated part W of a frame X, provided with transverse bearing

Digitized by Google

pieces X¹ arranged to slide upon guides O, and operated from the driving mechanism by similarly arranged levers and pusher N. Claims In rivet making machines of the kind described the stoppers G and special pusher T substantially as set forth.—No. 2889. February 22nd, 1890. 8*d*.

HYDRAULIC PRESSES.—*F. Horn & T. Keetman, both of Duisburg, Germany.*—Fig. 1 is a side elevation, and Figs. 2, 3, and 4 details of a press constructed according to this invention. The framework A, formed as shown, carries all the mechanism for actuating the hydraulic cylinder B sliding in guides C and carrying on its lower end the movable stamp D. The plunger of B is

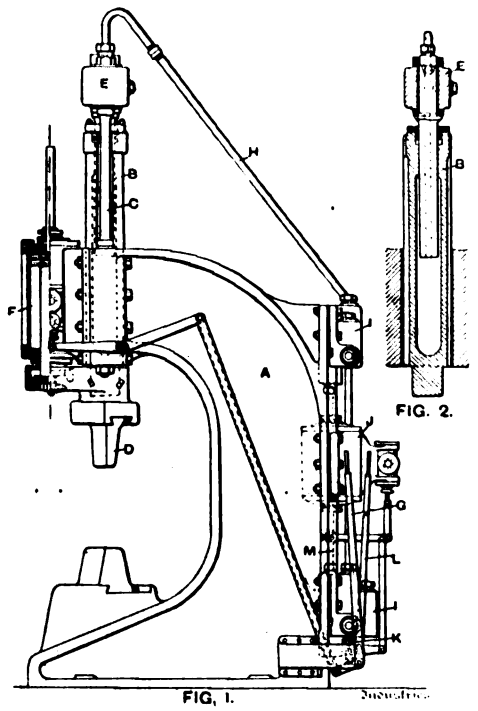

FIG. 2.

FIG. 1.

held by means of a cross-head E carried by C. The cylinder B is raised and lowered by means of the piston of the steam cylinder F, to the rod of which it is connected. The supply to the cylinder F is regulated by means of an unloaded piston slide valve operated by means of a hand lever G and suitable connecting levers. Water is supplied to the cylinder B through the plunger thereof (Fig. 2) and pipe H, the other end of which is connected with pumps I, the latter of which are connected with a water reservoir and are actuated from the piston of the steam cylinder J. The ascent of the hydraulic cylinder takes place upon the discharge of water, but as all the pump valves act as check valves a valve such as K (Figs. 3 and 4) is provided and is operated through hand lever G when this is moved to raise the steam piston in F. Figs. 3 and 4 are sectional views showing the connection of pressure pipe H with the suction or reservoir pipe past valve K. The pumps I are worked from steam cylinder J through hand lever L by displacing points. The effect of such displacement is, on the one hand, that the slide opens one of the admission ports bringing the pumps to work, and on the other hand that the slide by the movement of piston rod M, is brought back to close again, therefore a changed position of the hand

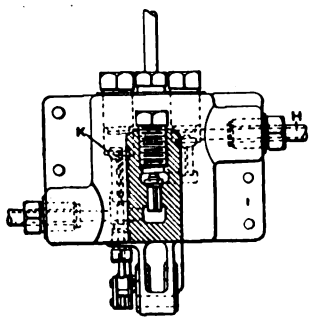

FIG. 3.

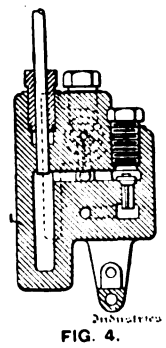

FIG. 4.

lever L brings about a proportionately changed position of the steam piston so that only such a movement of the slide valve is given as will effect a travel of the piston or pressure from stamp D corresponding to the nature of the work. Three claims are made.—No. 20675. December 18th, 1890. 8*d*.

GAS WASHERS.—*J. A. Kelman, London.*—The washer or scrubber constructed according to this invention is of a square or rectangular shape, and has a series of partitions, on which short tubes are mounted. Each tube has at its top end a dome shield fixed over it, the underside of which is provided with tangential vanes for breaking the gas up as it issues from the dome. Each of the partitions, which are fixed horizontally, is provided with an overflow for leading the water, which enters at the upper part of the casing from one partition to the other in succession. The pipes, through which the gas is first supplied to the lower chamber, project into this chamber above the water line, and have caps covering the upper ends thereof. Each of these caps is of curved formation on one side, and the dip from the curved portion is perforated for the passage of the liquor to the tar and liquor outlet, this having a check tube with openings at the bottom for the first exit of the tar, so leaving water on the surface, through which the gas has to pass. Each lower partition has its overflow pipe within a seal to prevent the gas rising except through the dome-covered tubes. The inventor also forms a condenser of a series of chambers superposed, and by a slight clearance around the tubes the gas flows from the upper chamber downwards. Seven claims are made.—No. 4824. March 19th, 1890. 8*d*.

ELECTRICITY.

INSULATED CONDUCTORS.—*E. F. A. Obach, Old Charlton, Kent.*—The invention relates to a method of preventing the action of sulphur in the insulating material upon the copper wires and their metal sheathings when used. For this purpose the inventor coats the wire with a gelatinous substance, such as glue, isinglass, and the like, and applies the vulcanised indiarubber or other insulating material containing sulphur. If a metal sheathing is used, the insulating material is then coated with a coating of gelatinous substance, and the sheathing applied immediately over it. Claims: Protecting electric conductors with their metallic sheathings from the action of sulphur contained in the material employed for insulation by interposing between the metal and the insulating material a coating of gelatinous substance, with or without paper or textile fabric, as described.—No. 4821. March 27th, 1890. 4*d*.

ELECTRICITY METERS.—*E. Hartmann & W. Braun, both of Bockenheim, Frankfurt-on-Main, Germany.*—The invention relates to an apparatus for measuring and registering at suitable intervals the quantity of electricity passing through a conductor. Referring to the annexed illustrations, Fig. 1 is a front elevation, Fig. 2 a side elevation, and Fig. 3 a detail of an apparatus for this purpose. The solenoid A, through which the current to be measured passes, has a core B formed (Fig. 3) of a piece of soft sheet iron wound around a spindle B¹ supported at its upper end by a spring C. The lower end of B¹ is connected to a lever arm of a spindle D geared with the registering mechanism E, the gear wheel, however, being only rotated in one direction by pawl E¹, and provided with a coil spring F acting by tension in opposition to the force exerted by A upon B. The spindle D also carries a pulley D¹, around which is wound a cord G connected to the armature H of an electromagnet H¹ wound with coils of high resistance and provided with a retarding device such as the piston and cylinder I. The pointer D² carried by D and working over a suitably graduated plate J is moved back to zero at

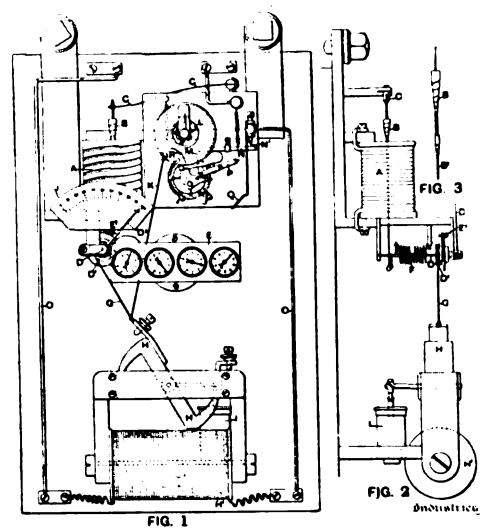

FIG. 3

FIG. 2

FIG. 1

given intervals by clockwork, allowing the current to pass through H¹. This clockwork, which may be of any suitable form, is driven by a spring which is automatically wound up by the action of H by means of a pawl and ratchet arrangement worked by a cord K. This clockwork being regulated by an ordinary balance L drives a cam or tappet M which acts on a contact making lever N. This lever, once in every revolution of the tappet M, makes contact at N¹ so as to put the electromagnet H¹ into circuit through the conductors O. When no current passes through the meter no electricity can circulate in the coils of the electromagnet, which then ceases to wind up the clockwork, and the latter runs down until the lever P comes in contact with the spring Q, and by the same movement engages with the brake lever R and causes the latter to stop the balance L. The contact at P to Q is connected with the contact at N¹ or with the electromagnet, and is so arranged as to enable the current to pass in the coils of the electromagnet H¹ directly the apparatus is put into circuit, thereby winding up the clockwork and releasing the balance. Four claims are made.—No. 18638. November 18th, 1890. 8*d*.

ALTERNATING CURRENT MOTORS.—*M. von Dolivo-Dobrowolsky & Die Allgemeine Electricitäts Gesellschaft, Berlin, Germany.*—The invention relates to such electric motors as are driven by a plurality of alternating currents of respectively differing phases. The improvements consist in an arrangement of the conductors serving to receive the operating currents. These conductors consist in a limited number of thick bars of a good conducting material, such as copper, the number depending upon the number of alternating currents employed. If, for instance, there is one pair of circum-rotating poles and two alternating currents, whose phases are shifted in respect to each other by a quarter of a phase, are used, four conductor bars are necessary, but if with two poles three alternating currents, having their phases shifted by a sixth of a phase, are used, six bars are wanted. These bars are passed longitudinally through, but insulated from, the body of iron composed of divisional parts such as discs. They are all electrically connected together by means of a disc, ring, or other means at one end, and at the other end are connected to the supply wires. Claims: In an electric motor driven by alternating currents of respectively different phases the combination with an iron body of a number of conductor bars passing through the said body and insulated therefrom: means for conductively connecting all the said bars together at one end, and a number of current-supply conductors connected to the other ends of the bars, substantially as described.—No. 20424. December 15th, 1890. 6*d*.

CHEMISTRY.

TREATMENT OF SEWAGE.—*G. W. Ewens, Bristol.*—According to the present invention the albuminous matter in the sewage is dissolved by the aid of either muriatic, sulphuric, or other acid when it becomes an adhesive mucus which readily adheres to all suspended matters, and that when in this condition by using an alkaline reagent, such as hydrate of lime, or slackened lime mixed well with water, or some form of soda or potass just sufficient to neutralise the acid, all this albuminous matter is immediately withdrawn from solution into suspension, and, being mixed with the suspended matter, the whole rapidly precipitates, leaving the effluent water pure. In carrying the above method into practice the inventor places a lead-lined tank at the head of the main sewers, in which the mixture of acid is effected so that when the sewage has reached the cleansing tanks the albumen will be dissolved, and the alkaline reagent may be added. The cleansing tanks are preferably three times as long as wide, and the floors should have an incline of about 1 in 200 from the receiving end to the overflow. When a tank is so full of sludge that it shows to the surface the flow is diverted to another tank and the superincumbent water discharged. This is effected by floating planks in the tanks of a suitable length and 3in. thick, and with holes perforated through them, in which holes are screwed the ends of 2in. tubes, so that the lower ends of the tubes are flush with the underside of the planks; to these pipes are connected iron pipes, let through the dam on a level with the floors of the tank. These siphon pipes are brought into action by pushing the planks under water. The sludge, when removed, is placed in suitable brick silos and covered over with a layer of clay, when, by fermentation of the organic matter, it will be dried. Four claims are made.—No. 1816. February 3rd, 1890. 6*d*.

DISTILLATION OF AMMONIUM CHLORIDE.—*J. Leith, St. Helens, Lancashire.*—The invention is designed to facilitate the use of an excess of ammonium chloride to Leblanc alkali waste, or other suitable sulphur compound of lime, and yet prevent the loss of ammonia. The inventor adds an excess of the ammonium chloride at the top of a distillation tower, and thus decomposes all the waste, but near the bottom milk of lime is added sufficient to decompose all the excess of ammonium chloride, which would otherwise be lost. The result is that all the ammonia is recovered, and the effluent gases are somewhat richer in ammonia as compared with the amount of sulphuretted hydrogen. Instead of alkali waste or sulphydrate of calcium, other sulphides of calcium may be used for this purpose. Claims: In the distillation of ammonium chloride with Leblanc alkali waste or other kindred substance, the use of an excess of ammonium chloride, and the addition near the completion of the process of milk of lime to the nearly exhausted materials containing the excess of ammonium chloride, whereby the latter is decomposed, and thus an increased relative proportion of ammonium chloride can be employed.—No. 2633. February 18th, 1890. 4*d*.

PRODUCTION OF CAUSTIC SODA AND CAUSTIC POTASH.—*J. C. Richardson, London, & T. J. Holland, Ivymeath, Snodland, Kent.*—The invention relates to the electrolytic production of caustic soda, caustic potash, and other productions of their salts. The inventors here dispense with the use of porous partitions in apparatus for the above purpose by the use of oxide of copper (CuO) placed next the cathode at or near which the caustic soda is formed. The mode of employing the oxide of copper is as follows:—In a suitable shallow tank containing a solution of common salt, the cathode is placed near the bottom, and is in the form of iron or copper gauze on which is placed the oxide of copper. At a suitable distance above this is placed the anode, formed of hard carbon rods or other chlorine resisting electrode. The action is as follows:—Upon the passage of an electric current the chlorine is set free near the anode and escapes out of the liquid, first charging the stratum of liquid above the lowest portion of the anode. At the cathode caustic soda is formed and concentrates at the bottom of the tank; the hydrogen in its nascent state combines with the oxygen contained in the oxide of copper. If instead of a caustic liquid and chlorine a hypochlorite be desired, as hypochlorate of soda, the position of the electrodes is reversed. Claims: In the electrical decomposition of salts of alkali or alkali earths in solution the employment of oxide of copper as and for the purpose described.—No. 2296. February 12th, 1890. 8*d*.

MISCELLANEOUS.

ENGINE PACKING.—*R. H. Attwater, Preston, Lancashire.*—The packing consists of non-corrosive soft metal wire and asbestos yarn intimately twisted together, which is then firmly plaited over and around a number of cores or cushions of flax which have been previously thoroughly lubricated with a non-combustible lubricant. Where great elasticity is required strips of indiarubber may be substituted for the flax yarn or four cores of flax and one of indiarubber may be used. Claim: The combination engine packing having central cores or cushions as and for the purpose herein set forth.—No. 19604. December 2nd, 1890. 4*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

MILLING CUTTER AND TWIST DRILL MACHINERY.

CONSTRUCTED BY MESSRS. HULSE & CO., ORDSAL WORKS, MANCHESTER.

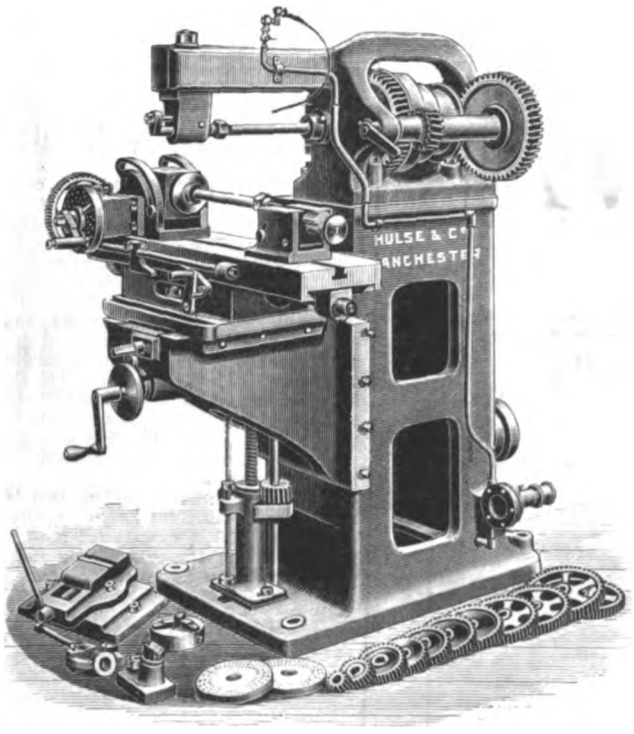

FIG. 1.

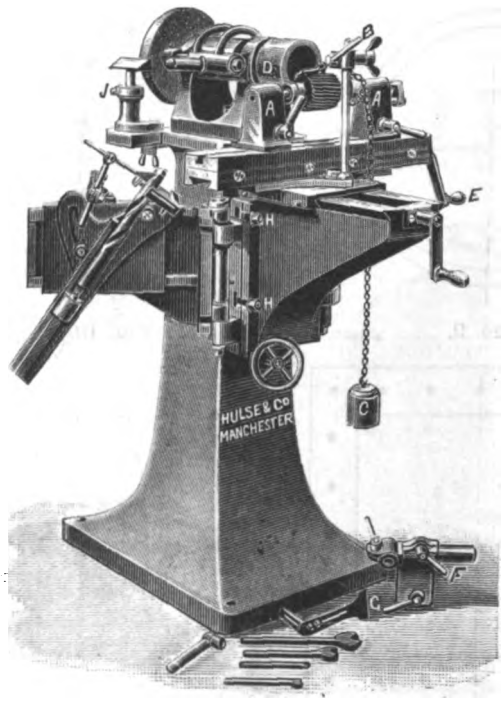

FIG. 2.

MILLING CUTTER AND TWIST DRILL MACHINERY.

WE illustrate above in Figs. 1 and 2 milling and grinding machines for making cutters and twist drills, designed and constructed by Messrs. Hulse & Co., Ordsal Works, Manchester. The milling machine (Fig. 1) is constructed with a strong hollow stand, in which there is provision for the storage of loose tools and lubricant. The headstock has a four-speed cone and is double geared, all the wheel teeth being machine cut. There is an overhanging arm cast solid with the mandrel frame, in order to afford steadiness in working. The table has vertical, longitudinal, transverse, and swivel slides, is strongly made, and is fitted with a universal dividing headstock which can be set to any angle between the horizontal and vertical. Two movable headstocks are provided to work with the dividing headstock, one of the ordinary type, and the other with a triangularly shaped swivel spindle to suit twist drill work of small diameter. The self-acting traverse is obtained without the use of universal joints common in the American type of machine, these being substituted by worm and mitre gearing, driven from the main spindle through cone pulleys. An automatic stop motion is also fitted. For spiral work the feed screw rotates the spindle of the dividing headstock during the traverse of the table, the angle of the spiral being determined by change wheels between the two spindles. The machine, as illustrated, is of medium size, and the table has a transverse movement of 21in., and a longitudinal traverse of 7in.

The machine used for sharpening cutters is illustrated in Fig. 2. The apparatus for cutters is hinged on one side of the machine and that for twist drills on the other, so that each can be used when required. For cutter grinding the cutters are placed on an arbor between the centres A A and held against the guide finger B by the chain and suspended weight C. They are ground by a face emery disc D, which, being large in diameter, does not wear perceptibly in going round a cutter, and has the advantage of producing a straight "back-off" instead of the curved one arising from peripheral grinding. Cutters with teeth to be ground on their faces are carried by the universal headstock F and held in position by the finger G. For twist drill work the requisite clearance behind the lips is obtained by the action of the large emery discs and rests J at the back of the machine, one operation only being required. The drill is then placed with its shank end in the small headstock carried on the radial bracket, and its upper end supported by a semi-circular recess in a rectangular plate, a set of the latter being furnished. The bracket is adjustable radially, and the guide-finger holds alternately the lips in position. The machine is very rigid, and can deal with cutters up to 8in. diameter and 12in. long, and twist drills from $\frac{1}{4}$in. to 3in. diameter.

THE HULL AND DISTRICT INSTITUTION OF ENGINEERS.

THE members of this Institution held a meeting on the 10th inst., the President, Mr. C. F. Amos, being in the chair, when an interesting paper was contributed by Mr. J. Brackenbury (Messrs. Amos & Smith's), on "Pumps and Air Vessels." In the paper the author referred to various types of pumps in common use, and gave the respective merits and advantages of different types. The delivery rate from single-acting, double-acting, three-throw, and four-throw pumps was shown by diagrams, which were based upon the assumption that the pumps were actuated by a uniformly rotating shaft. The mean delivery being taken as 100, single-acting pumps had a maximum of 314 and a minimum of 0; double-acting pumps, a maximum of 157 and a minimum of 0; three-throw pumps, a maximum of 104 and a minimum of 90·5; four-throw pumps, a maximum of 111 and a minimum of 78. The author showed how the irregularities of delivery could be minimised by the use of air vessels, which in any particular case would confine the variations between certain limits; and also how the correct capacity of air vessels depended on the pressure, the type of pump or pumps, and the variation of pressure which it was intended should exist. General formulæ and diagrams for pumps and air vessels were given and explained. Several applications of the formulæ to air vessels which had come under the author's observation were also given. The case of feed pumps on engines was specially treated, and the general conclusion arrived at was that feed pumps should be independent of the engine, and be of the three-throw or four-throw type, if a thoroughly reliable working result was desired.

A communication from Mr. J. C. Amos was read, which described an ingenious automatic arrangement for keeping air vessels fully charged with air, and which is in successful use at several large waterworks in the country. The writer further showed the necessity of fixing air vessels on long mains, to take up shocks, and thus prevent breakages.

An interesting discussion followed the reading of the paper. At the next meeting of the Institution a paper on "Refrigerating Machinery" will be contributed by Mr. J. C. Amos.

THE ORDNANCE SURVEY.

THE paper recently read by Sir Charles Wilson before the Society of Arts, on the "Methods and Processes of the Ordnance Survey," gives a considerable number of interesting details concerning a matter to which we directed the attention of our readers in our issue of the 30th January, and which will well repay careful study on the part of those interested in the matter. It is just a century ago since a trigonometrical survey of the country was ordered for the purpose of producing a military map, and six years later it was decided to publish a general map of the kingdom, founded upon a minute survey. The first sheet of this map was on a scale of 1in. to a mile, and was published on the 1st of January, 1801. In 1824 the survey was partially suspended in order that Ireland might be surveyed on a scale of 6in. to a mile, for a general land survey. In 1840, the survey of Ireland being almost completed, it was decided to continue the survey of Great Britain on the 6in. scale instead of the 1in. scale, and this arrangement was carried out until 1851, when there commenced a Parliamentary struggle, which has not inaptly been called the "battle of the scales," and during the twelve following years the subject was discussed by a Royal Commission and three Select Committees of the House of Commons. During the progress of the battle a large sum of money was absolutely wasted. Finally, in 1863, it was definitely arranged that the undermentioned plans and maps were to be published:—(1) Town maps, on a scale of $\frac{1}{500}$; (2) parish plans, on a scale of $\frac{1}{2500}$; (3) county maps, on a scale of $\frac{1}{10560}$; (4) a topographical map, on a scale of $\frac{1}{633600}$; (5) a map of the United Kingdom, on a scale of four miles to the inch; (6) map of the United Kingdom, on the scale of ten miles to the inch. Since 1863, the only changes of consequence that have taken place are:—The authorisation, in 1872, of a new 1in. map of England and Wales, based upon the cadastral survey; the issue of authority to revise the maps of Great Britain in 1886; and the order issued in 1887 to publish Ireland on the $\frac{1}{2500}$ scale.

Sir Charles Wilson gave a most interesting account of the methods and processes of the Ordnance Survey, but for this we must refer our readers to the paper, which will be found to be of great value not only to students of engineering, but also of interest to general readers. Our present object is chiefly to direct attention to the subject of our former notice of the survey—that is, the necessity for revision. Sir Charles admits that the revision of the survey has unfortunately fallen very much in arrear, so much so, in fact, that in many places revision means a re-survey. The necessity for revision has frequently been pointed out by the officers who have had charge of the survey; but it was not authorised until December, 1886, and since that date the Department has been fully occupied in placing Lancashire and Yorkshire on the large scale. The question of revision is purely one of money, and Sir Charles Wilson showed that the work is a much larger and more complicated one than is generally supposed, and involves a very large expenditure. In view of a periodical revision, the kingdom has been roughly divided into revision districts, and, as opportunity offers, the division offices are being moved into centres, which

Digitized by Google

will probably be permanent. Arrangements are being made for preventing new work from falling into arrear, and the time taken to clear off the old arrears will depend entirely upon the annual grant to the survey.

Sir Charles Wilson pointed out that in the utilisation of the Ordnance Survey maps the Irish Government is quite twenty-five if not fifty years in advance of England. In Ireland townland boundaries and areas, as ascertained and shown upon the Ordnance Survey maps, are the legal boundaries and areas of the townlands, and so satisfactory is this arrangement found that disputes as to townland boundaries are unknown. The Irish Valuation Acts provide that the Ordnance Survey maps are to be used in ascertaining the areas of tenements, and a very good system of valuation is in force. In Ireland, moreover, all land is sold in the Land Judges' Court by the aid of maps prepared by the Ordnance Survey, and all maps on title deeds are drawn by the Department. In England the case is very different. There is a special Boundary Division, charged with the ascertainment of boundaries, which prepares elaborate reports and maps of all boundaries, and the area of every parcel is accurately computed. Yet the boundaries and areas on the Ordnance Survey maps are not legal, and the maps are rarely used for local assessment or administrative purposes. The nation deliberately undertook this elaborate survey on the ground that no private enterprise could accomplish it satisfactorily; and now, after spending millions on its production, England hesitates to make use of it in the manner intended by the able statesmen and scientific men upon whose recommendation it was authorised by the Government of the day. Sir Charles Wilson pointed out that the actual cost of production of the maps in England can compare favourably with foreign countries, and that the higher prices as compared with foreign maps arise from the heavy commission paid to the map agent. Our correspondent, Mr. Crook, informed us that the Committee of the British Association, appointed at Leeds, was taking steps to have these and other matters pressed upon the public and the Department. He feared, however, that little improvement will be made until public opinion is better instructed. He pointed out that it is from public interest alone that the impulse can come to move Parliament and the Government to make the necessary provision, without which the existing deficiencies of the work of the survey cannot be remedied. It is for this reason that we have again directed attention to the subject.

Railway Construction in India.—During the past year, from 1st April to the 15th of November, 255½ miles of new railway were opened for traffic in India. This includes 45 miles on the Bengal-Nagpore Railway, and 57 on the Tirhoot line, and 63 on the Southern Maratha Bellary-Kistna section.

RESULTS OF EXPERIMENTS ON THE STRENGTH OF BOILERS.*

(*Concluded from page* 245.)

APPENDIX.

The basis of the author's former paper on this subject was the proposition that if a cylinder be made in two halves, bolted together at the centre, as in Figs. 9 and 12, the tensile strain on the bolts in the flanges, due to any pressure in the cylinder, is absolutely independent of the form of the vessel. It depends only on the area of ABCD and the pressure, and remains the same if one of the halves of the cylinder is removed and replaced by a flat plate, or by a half cylinder with its axis at right angles to the bottom half, or by any other shaped cover, provided that cover is strong enough to transmit the pressure on it to the bolts.

That this proposition is axiomatic did not then, and does not now, appear to him to be a question about which there can be any difference of opinion amongst engineers. Neither does it appear doubtful, that if the two halves of this vessel were joined together without flanges by the shell and end plate being continuous, that the strain on these plates must be the same in amount and distribution as on the bolts. To one saturated with the theory that the strength of boiler shells depends only on their resistance to circumferential tension, it was natural to infer, from an argument proving that in certain cases the circumferential tension is only a certain fraction of that formerly assumed, that in those cases the thickness of shell plate might be reduced in proportion to the diminished tension. The writer's experiments have proved the error of this inference which he had formerly drawn. He is now convinced that none of his models yielded primarily to circumferential tension, but to other strains not hitherto reckoned on, and in ways which he did not anticipate and cannot now calculate on. Whether this is so or not, there are some reasons for thinking that pressure within a boiler tends to stretch the end plates as well as the shell; and there are good reasons for suspecting that the contrary assumption is not true, or at least not the whole truth. He therefore proposes to trace the consequences of the first assumption as far as he can.

To simplify matters, suppose a cylinder of uniform strength throughout, without any joints, the end plates being of the same thickness as the shell plates. Ignoring the staying of end plates, and confining the attention to strains derived from the shell plate, let the cylinder be, say, 20in. long × 20in. diameter, subject to a pressure of 100lb. to the inch. Let it be further assumed that the thickness of the shell plate is sufficient to transmit any strains that may come upon it. Of course, it cannot be questioned that a uniform circumferential tension throughout the shell plate

$$= \text{radius} \times \text{pressure} = 10\text{in.} \times 100\text{lb.} = 1{,}000\text{lb.}$$

would exactly balance this pressure; but an essential condition of this solution is that the shell plate must be free to stretch uniformly throughout its length, which it is not so long as the ends offer any resistance.

If ACBD, Fig. 10, is the end plate of this cylinder, any pressure transmitted to it from the shell will be uniform all round the circumference, if this pressure is p lb. per inch acting radially, and if $klmn$ is a vertical strip in this plate, the vertical component of the radial pressures on the curves kl and mn will produce a tension $= p$ lb. per inch, tending to stretch the strip in the direction of its length; and in the same way the pressure on ACB and on BDA will produce a uniform tension $= p$ lb. per inch, tending to split the plate through AB, or to stretch the plate in the vertical direction. This is, of course, true for all other diameters.

Again if ABCD, Fig. 12, is a square, the strain on the bolts in the flange AB will be the same as the strain on the bolts in the flange BC. In the same way as EF (Fig. 11) = AB (Fig. 10) the section through the cylinder is a square, and the strain on the section of plate at EF will be the same in amount and distribution as the strain on the section of the end plate at AB. It has been proved that the strain on AB is a uniform tension $= p$ lb. per inch, therefore the strain on EF is also a uniform tension $= p$ lb. per inch. The pressure tending to rupture the cylinder, through AB and EF = 20″ × 20″ × 100lb. = 40,000. If this is resisted by a uniform tension $= p$ lb. per inch in the two sections of shell plate, and the sections of the two end plates, then—

$$p \times 2\,(20'' + 20'') = 40{,}000\text{lb.}, \text{ or } p = \frac{40{,}000}{80} = 500\text{lb.}$$

As all the central sections of a cylinder are alike, it may be said that, under the assumed conditions, 100lb. pressure within the cylinder will be balanced by a uniform circumferential tension in the shell plate of 500lb. per inch of length, and a uniform shearing strain of 500lb. per inch of circumference at the junction of shell with ends. Now, a circumferential tension of 500lb. per inch will exactly balance a pressure of 50lb. on the shell, because 50lb. × radius = 50lb. × 10in. = 500lb. The problem may therefore be divided into two parts. The shell, considered as an endless ring, sustains a pressure of 50lb. to the inch, and considered as a beam supported at the two ends, it also sustains a pressure of 50lb. to the inch. The first part presents no difficulty; the second part is not so simple, but still some steps towards its solution can be taken.

In the first place it is evident that in this beam the bending moment in any direction, say vertically upwards, due to pressure on the top half, is exactly balanced by an equal and opposite moment due to the pressure on the bottom half, and that all bending moments cancel each other. The next point to be considered is the distribution of shearing strains throughout the beam:—

If ABCD (Fig. 13) is the outline of the beam,
XOX being the axis of the cylinder,
YOY being the centre of the length,
ab cd is a ring 2*x*in. wide.

If a pressure of 50lb. per inch on this ring is transmitted to the two ends it must produce a strain $= 50 \times x$ on each side of the circumference on the two circles *ac* and *bd*. This pressure acts radially and tends to shear through the plate all round the circumference, and is resisted by the resistance to shearing of the plate. The shearing stress at the point A will be 50lb. × AY = 50lb. × 10in. = 500lb. per inch of circumference. If AE = 500lb. on any scale, the line EY will give the shearing stress at any point; thus at the point (*a*) the stress will be given by the length of the line *ae*. Thus if any pressure is transmitted to the ends of the beam, it will be transmitted as a shearing stress increasing uniformly from 0 at the centre to a maximum value at the ends. The same result would be obtained if we had commenced by assuming that the ends offered a resistance = 500lb. per inch, or it might be stated as a particular case of the general law of shearing strains in beams uniformly loaded.

The conclusion arrived at is, that a pressure of 100lb. per square inch in this cylinder will produce a uniform circumferential tension in shell = 500lb. per inch of length, and a shearing strain on the shell varying from 0 at the centre to 500lb. per inch of circumference at the two ends. The result of these strains on the cylinder is the next thing to consider. Suppose a tension of 500lb. per inch would stretch the shell plate $\frac{1}{n}$th part of its length, this would correspond to a uniform increase in diameter of shell $= \frac{1}{n}$th part of diameter. And, as previously stated, a stress of 500lb. per inch applied to the circumference of the end plates would produce a tension of 500lb. per inch in every diameter of the end plate, as the end plate is assumed to be the same strength as shell plate. This tension would stretch the end plate $\frac{1}{n}$th part of its diameter, and, consequently, as both shell and ends would be increased by the same amounts, the cylinder would remain a parallel cylinder, $\frac{1}{n}$th part greater in diameter than before pressure was put on.

Up till now it has been assumed that the pressure is such that any strain produced by it will not exceed the elastic limit of the resistance of the shell to that strain. But if the pressure is increased beyond this limit it will be seen that the distribution of strain will no longer continue as above. If there are any weak points in any structure, say a line of rivet holes in a boiler plate, the strain which would normally be distributed along the whole line is concentrated on the metal left between the holes. And in the same way if pressure within a cylinder is resisted both by the resistance to shearing and the resistance to tension of shell plate. If one of these resistances fails to sustain its normal share of the pressure, then the other will have to sustain more than its share.

Thus if ABCD (Fig. 14) is an outline of the cylinder, XX being the axis, the normal distribution of strain brings one-half of the total pressure on the two ends and the other half on the ring as tension. If, now, it were possible to shear through the connection between shell and end plates, without allowing the pressure to escape, then the whole of the pressure would come at once on the ring, and the pressure which was formerly producing shearing strain would then produce circumferential tension. Or, again, the pressure acting on AB might find it easier to bulge the cylinder at some distance from the ends than to shear through it at the ends. If the shearing stress at *m* and *n* were greater than the elastic limit of the resistance to shearing at these points, then they would begin to bulge rapidly, but they could not bulge without increasing the diameter of cylinder, and this would be resisted by the circumferential strength of plates, and as the resistance of the ends decreased the strain on shell as a ring would increase. If the pressure could be increased after the shell began to bulge near the ends the decreasing support from the ends and the increasing strain on the ring would cause the crest of these bulges

to travel towards the centre, and give the barrel form which was assumed by Model No. 8.

In this connection it is instructive to notice that in Mr. Scott's experimental boiler the form shown in Fig. 7 may be observed getting gradually more pronounced as the pressure rises to 580lb., where the structure was evidently strained up to or beyond its elastic limit, and that the next increment of pressure destroyed this form by greatly increasing the bulge on centre course, a result probably due to the fact that the end courses were unable to transmit any more pressure to the ends, and therefore the additional pressure only increased the circumferential tension. Such a distribution of strain is consistent with all the results of these experiments. If the circumferential tension is much less than that ordinarily assumed, it can be easily seen how all these models stood a much greater pressure than can be accounted for on that assumption. It accounts for the form taken by Models Nos. 1 and 2. And if in No. 3 the plate had begun to yield in a similar manner at an equal distance from its ends, as in the longer models, it can be easily understood that, as the distance between these points would be very small, the additional strain brought on the short ring between these two humps, by the ends failing to transmit their proportion to the ends, would produce the barrel form that was produced. And, as in this case the pressure was applied very quickly, and the space for leakage was very small, it was possible to follow up the yielding ends until the joint at the centre burst, a result which could only be obtained where the supply of water was enormous in comparison with the size of vessel.

A strain of this character tending to increase the diameter of the ends more than the centre, if the resistance of the ends to increase of diameter was greater than the resistance of centre to contraction, might account for the contraction observed in Model No. 1. If Nos. 1 and 2 were destroyed by a strain normal to the circumference, this would account for the fact that the solid plates suffered as much as the weak joint, a fact not easily explained if circumferential tension were the strain that destroyed these models. The only fact not explained by this hypothesis is that these models yielded near and not at the ends. If the reason why these plates failed to transmit more than a certain strain to the ends, and the limit of their resistance were known, the problem would be solved.

In conclusion, the writer considers he is justified in assuming that, in any boiler working, as all boilers ought to work, at a pressure much below the elastic limit of the structure, the pressure is not balanced solely by circumferential tension in the shell plate, but is uniformly distributed over any central section through shell and ends. That this distribution of strain will continue until, as in these models, the elastic limit of resistance to shearing has been exceeded. After which, the proportion of pressure balanced by circumferential tension will be increased; but it can never be the sole resistance until the connection between shell and ends has been entirely destroyed.

THE MECHANICAL TREATMENT OF MOULDING SAND.*

LITERATURE on the art of founding, and on the materials employed in the moulding of iron, steel, and brass, is unfortunately scanty, owing no doubt partly to the lack of the same personal interest in the foundry that is taken in other departments of engineering works; and in a large number of instances this want of familiarity with foundry practice causes the production of castings to depend on the experience of individual workmen. If a "waster" casting be the result, it is invariably and not unnaturally attributed to accident, when it may be more probably due to want of skill; for even moulders themselves are not generally credited with a scientific knowledge of the principles on which their art depends. In large shops there is, of course, a competent foreman, who is responsible for the execution of orders in the most economical way; whereas in smaller foundries even important work, such as the preparation of cores and mixture of sand, is not infrequently carried out by unskilled workmen in a rather empiric manner. On the subject of the present paper there seems to be as much difference of opinion as there is diversity in practice; the writer, therefore, hopes discussion may help to settle debatable points. Some moulders place faith only in kneading or treading the few simple materials composing their facing sand, jealously guarding the preparation as a trade secret, and condemning all machine work; whilst others are equally emphatic in favour of the particular machine for grinding, riddling, or combing, to which they have been accustomed.

Sand.—Before describing the foundry processes in use it may be interesting to examine specimens of the ingredients generally incorporated. Fig. 1 is a view, considerably magnified, of sand found and much used in the West Riding of Yorkshire. In its natural state it will be noticed that a portion of the grains adhere together in clusters, varying in size from masses containing hundreds of sand grains to smaller groups of three or four grains, most of them small enough to pass through an ordinary fine riddle without disintegration. The form and size of the groups are very irregular, and many are covered with a fine scaly powder. Samples from the bulk show a preponderance of grain groups devoid of any uniformity. There are exactly the same appearances in fine Mansfield and other sands, though the presence of sharp crystals may be more frequent, and the abraded corners not so conspicuous. Fig. 2 represents new sand mixed with coal dust and burnt sand. The black spots dotted over the new grains are particles of coal which attach themselves in this manner, and when subjected to the heat of molten metal are converted into coke, often enveloping the sand grain with a crust, as shown in Figs. 3, 4, and 6. In none of the specimens examined was coal found in a separate loose state. Figs. 3 and 4 show samples of old sand very much like gas coke, with perhaps more of a metallic lustre. Fig. 5 shows the extent to which sand may be destroyed by burning or chemical action. Numbers of these friable hollow husks occur in a more or less broken condition, and are easily reduced to fine powder by concussion with other particles. If used again in sufficient quantity they will cake and cause metal to boil. Fig. 6 illustrates the formation of a shell round a sand grain; the shell may be cracked like a nut, exposing a kernel of clean sand. Coal dust, as commonly found, takes the form of angular splinters with laminated surfaces. When considerably magnified (Fig. 7) it appears only like a fine powder; the larger pieces are not present in quantities, if the coal has been properly ground. These materials, after incorporation, are generally coated with some other substance, plumbago being the most preferred; but it is difficult to give a correct impression of this article in a drawing. The flakes shown in Fig. 8 are taken from a surface polished with black lead, presenting to the naked eye merely its own peculiar lustre over a large area. When viewed in bulk it is fluffy, like soot; and the outlines of separate flakes are not well defined by the prevailing light and shade.

The chemical composition of sand will obviously affect the nature of the casting, no matter what treatment it undergoes. Stated generally, good sand is composed of 94 parts silica, 5 parts alumina, and traces of magnesia and oxide of iron. Sand containing much of the metallic oxides, especially lime, is to be avoided. Geographical position is the chief factor governing the selection of sand; and whether weak or strong, its deficiencies are made up for by the skill of the moulder. For this reason the same sand is often used for both heavy and light castings, the proportion of coal varying according to the nature of the casting. A common mixture of facing sand consists of six parts by weight of old sand, four of new sand, and one of coal dust. Floor sand requires only half the above proportions of new sand and coal dust to renew it. German founders adopt one part by measure of new sand to two of old sand; to which is added coal dust in the proportion of one-tenth of the bulk for large castings, and one-twentieth for small castings. A few founders mix street sweepings with the coal, in order to get porosity when the metal in the mould is likely to be a long time before setting. Plumbago is effective in preventing destruction of the sand; but owing to its refractory nature it must not be dusted on in such quantities as to close the pores and prevent free exit of the gases. Powdered French chalk, soapstone, and other substances are sometimes used for facing the mould; but next to plumbago, oak charcoal takes the best place, notwithstanding its liability to float occasionally and give a rough casting.

Hand Riddling and Treading.—For the treatment of sand in the moulding shop, the most primitive method is that of hand riddling and treading. Here the materials are roughly proportioned by volume, and riddled over an iron plate in a flat heap, where the mixture is trodden into a cake by stamping with the feet; it is turned over with the shovel, and the process repeated. There is no doubt that tough sand can be obtained in this manner, its toughness being usually tested by squeezing a handful into a ball and then breaking it; but the process is very slow and tedious, and consequently expensive if tried on a large scale. Other things being equal, the chief characteristics of a good moulding sand are toughness and porosity, qualities that depend on the manner of mixing as well as on uniform ramming; indeed, the same result would follow from want of attention to the one as to the other. For instance, it is well known that a mould rammed too tightly in one place and loosely in another will cause a swelled uneven surface on the casting. Similarly, if quantities of fat sand and poor sand occur alternately through improper mixture, the power of resisting the pressure of the molten metal is not equal, apart from the liability of causing the metal to scab, and a wavy rough surface will be the consequence. In America a moulder will often prepare his own sand by hand riddling and treading, rather than have it put through a machine. For the pneumatic method of moulding with compressed air and flexible pressure-plate, it is claimed that it gives sand of uniform density at all points equidistant from the pattern; yet in this system, as in hand moulding, the thorough mixture of the sand is of the first importance. The practice of piercing the mould with a vent rod will never give results equal to those realised with sand having its ingredients properly incorporated.

Power Riddling.—It is only a step from hand riddling to power riddling; and the latter has been made to approach as nearly as possible to the former by a succession of impulsive movements for the purpose of opening out the sand. Usually a power riddle, as shown in Fig. 10, consists of a set of transverse horizontal bars called breakers, placed over a coarse riddle, below which again is a fine riddle, the whole being set slightly sloping downwards towards the outer end. Lumps that do not pass through these roll off into a heap at the lower end. The frame carrying the bars and riddles is suspended from straps, and oscillated by a crank or cam. For quantity, this mode of mixing is a decided advance on the slow hand process, though it presents the objection of not opening out the groups of grains.

Roller Mill.—Another means of treating sand is the roller mill (Fig. 11), which is said to answer very well for hard sand containing stone. With soft sand the writer's experience has not been favourable to rolling, inasmuch as the castings made with sand so treated show a strong tendency to scab; but other founders state they do not find any serious disadvantage from its use. Viewed through a microscope the effect of slight pressure on sand would tend to confirm the writer's opinion; sand was placed between two slips of glass on the microscope stage, and a gentle sliding movement being given to the upper slip by the thumb of one hand, the rounded grains were seen to fly asunder into sharp crystalline forms, as depicted in Fig. 9. It is true that only those grains in immediate contact with the rollers would be thus violently acted upon, the rest forming a cushion; yet the former must be a considerable percentage of the whole quantity. If all the sand were actually crushed, the result would be the reverse of beneficial, for it would be too fine, and the fragments would form so close and dense a mass as to render it impervious to gas.

Centrifugal Mixer.—Schütze's centrifugal mixer, shown in Figs. 12 to 14, combines the advantages of all the other plans, besides giving a considerably greater output of sand. The particles of clay or groups of sand grains are so thoroughly disintegrated and mixed with the coal dust that the gas generated in the mould can get round every particle of sand, and so escape easily and equably, which is a desideratum for a fine casting. Agglomerated sand in large lumps, too big to pass through any riddle, comes out of the centrifugal mixer in a fine powdery condition along with the other materials; consequently no previous sifting is required. In ordinary work the materials are placed in layers, sandwich fashion, on the floor, in a convenient position for being shovelled into the hopper of the machine, through which they are passed as fast as two men can shovel them in. The actual quantity thus mixed is at the rate of 12 tons per hour, or a ton in five minutes. The action of the machine will be readily understood from the illustrations. The revolving table, shown in Fig. 12, is mounted on the top of a vertical spindle, and carries on its upper face a number of vertical pins or beaters, fixed alternately in a series of concentric circles, Fig. 13. The table is driven by a 3in. belt (Fig. 14) at the rate of 1,200 revolutions per minute. The cover of the table has a hinge for turning it up in order to allow pieces of metal or other foreign substances to be readily taken out, which can be done at any time in only a few minutes. Falling upon the centre of the table from the hopper above, the sand is projected at a great speed from one row of pins to the next, until every part has been combed out. Round the outside of the table an indiarubber shield guides the sand into a circular heap after it has been whirled from the table. Moulds made with riddled sand and with sand mixed by this centrifugal machine—one half of the mould being made with each kind—certainly induce a preference for the machine mixing, after examination of the skin on the casting. Moreover with the machine one man can do the work of several in the preparation of the sand, thus securing economy in time and wages. This machine was first seen by the writer when in Germany, where there are 400 now at work; and he was so much struck with its simplicity and efficiency that he ordered one for his own works, and found the result of its adoption to be a great saving in wages and better work. The prejudice, however, in favour of existing methods is so great that few other works in England have as yet ventured to adopt it. In response to inquiries concerning the cost of mixing sand by hand labour and by machine, only two firms out of twenty applied to could give any estimate. Longer life of the sand is ensured by the complete intermixing of the materials; the reason for this may be seen in the protecting coat or shell shown in Fig. 6. Moreover, a more even surface must result from the fact that, while the clay in the sand contracts under heat, the coal expands.

Toughness of Sand.—In order to test the relative toughness, sand mixed in various ways was pressed under a uniform load into bars 1in. square and about 12in. long, and each bar was made to project further and further over the edge of a table until its end broke off by its own weight. Old sand from the shop floor had very irregular cohesion, breaking at all lengths of projection from ¼in. to 1¼in. New sand in its natural state held together until an overhang of 2¾in. was reached. A mixture of old sand, new sand, and coal dust—

mixed under rollers,	broke at 2in.	to 2¼in.	of overhang;
,, in the centrifugal machine	,, 2in.	,, 2¼in.	,,
,, through a riddle	,, 1¾in.	,, 2¼in.	,,

showing as a mean of the tests only slight differences between the last three methods, but in favour of machine work. In many instances the fractures were most uneven, so that minute measurements were not taken. Tests for porosity were also made by putting the various sands into a tube, and forcing air through. These, however, have no practical value, because the conditions when in contact with molten metal are quite different.

Working Expenses.—Although the centrifugal machine will actually mix twelve tons per hour, it is not assumed that this quantity would be passed through it continuously; therefore a moderate estimate of only thirty tons per day is taken in the following data. The power will of course vary with the work. No dynamometrical test has yet been made with the machine working to its full capacity; the power is calculated from the belt, and a belt of an inch width running on the fast pulley will suffice. A machine in Devonport Dockyard takes one horse-power when mixing two tons per hour, or about half the power allowed in the following estimate:—

	s.	d.
One labourer for 9 hours	4	0
Three horse-power for 9 hours	1	1½
Depreciation 10 per cent. on £33 for 300 working days per year		2½
Repairs 5 per cent.		1½
Interest 5 per cent.		1½
Total per day	5	6½

The cost per ton is therefore nearly twopence. Messrs. Marshall, Sons, & Co., Gainsborough, have three men employed on one machine to mix sand for 150 moulders and 14 moulding machines; but eventually their system will reduce this to one man's work. Other firms find one man working 9 hours per day can serve 60 moulders.

Equivalent Hand Labour, &c.—The average output in riddling and treading sand is 4 cwt. per hour per man, which with wages at 5d. per hour gives 2s. 1d. as the cost per ton, or twelve times more than by the centrifugal machine. As no exact cost of mixing sand by other systems at present in use could be ascertained, no allowance is made for power, depreciation, and repairs; for wages only the cost of mixing by power riddling amounts to 1s. 8d. per ton, and by rollers to 1s.

Durability.—After two years' working of the centrifugal mixer no expense of any kind has yet been incurred for repairs. The working parts are so few that the cost of maintenance leaves nothing to be desired.

THE CHANNEL TUBULAR RAILWAY.

WRITING to the *Times* on this scheme on the 11th inst., Sir E. J. Reed remarks:—"In conformity with a courteous intimation which I received from the Secretary of State for War at the end of last week, I find in to-day's 'Votes and Proceedings' of the House of Commons notice of his intention to move that my Bill for sanctioning the construction of this railway be read six months hence. I am less concerned at this notice than might be supposed, because, although I thought it my duty to submit my plans to the War Office, to which the Board of Trade would probably make reference, my tubular railway (unlike the tunnel) really is not a matter of direct concern to the War Department, because it would devolve upon the Navy, and not upon the Army, to prevent the use of the railway by a hostile force. Hitherto the Board of Admiralty have not expressed any opinion upon my system, and it was only yesterday that I had the opportunity of going over the plans with the naval authories. I am hoping also to have a further interview with the Board of Trade. It will be my desire to meet the scruples—for I can hardly believe in the existence of more than scruples—of the War Office if

THE "PYROS" FEED-WATER HEATER AND CIRCULATOR.

CONSTRUCTED BY MESSRS. A. W. ROBERTSON & CO., ENGINEERS, LONDON, E.

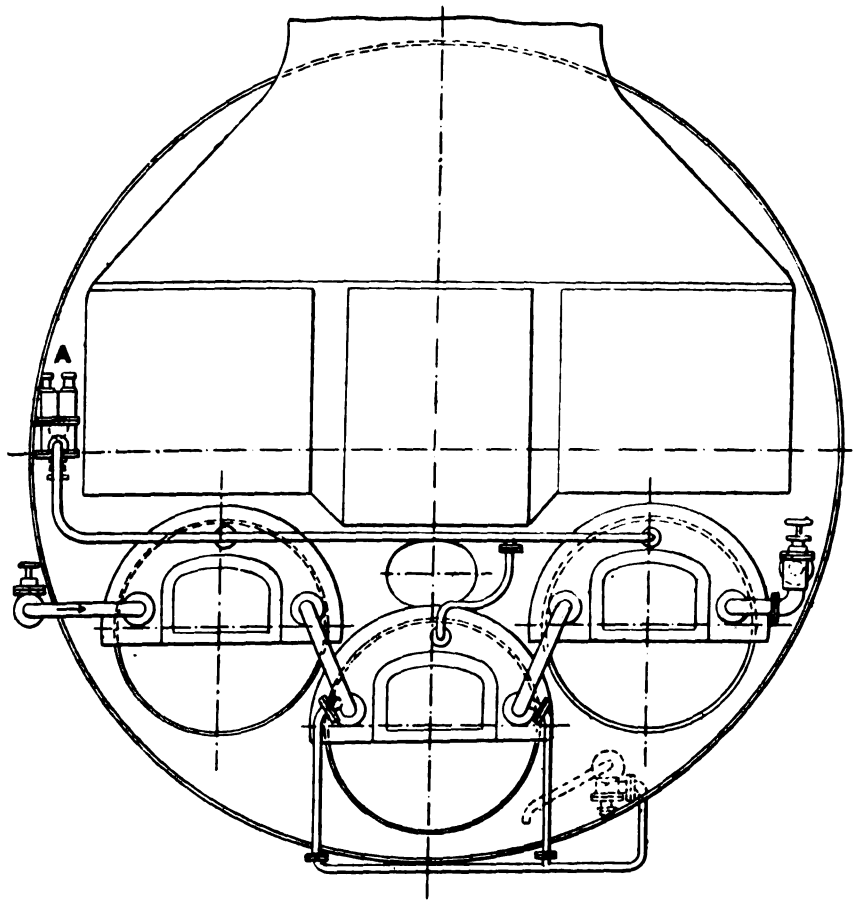

FIG. 1.—FRONT ELEVATION.

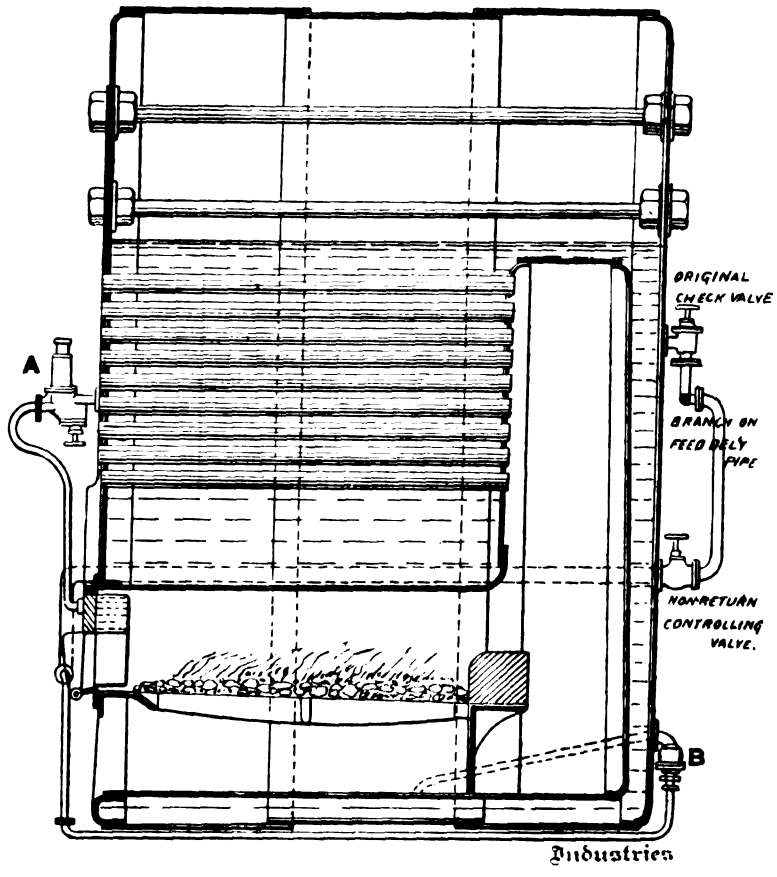

FIG. 2.—SECTIONAL ELEVATION.

possible, and to this end I shall be willing, if desired, to postpone the second reading of my Bill in the House of Commons at least until after Easter; but, knowing as I well do that many members of the House who always oppose the tunnel are quite ready to vote for my Bill—my scheme in their estimation, as well as in my own, affording the country abundant guarantees against the military abuse of the railway—I shall have carefully to consider whether I should do right in refusing the House an early opportunity of pronouncing its judgment by making a longer postponement. I must be allowed to say that I feel glad to know that it is only from the War Office at present that the Government opposition comes, for the War Office obviously are not entitled to anything like a decisive voice in this matter. Every inch of the twenty odd miles of this railway will be exposed to naval attack should an enemy dare to attempt to make use of it, and for that reason it is obvious that the voice of one or two military officials at Pall Mall or the Horse Guards cannot alone debar the country—may I not say the Empire, or even the world?—from some readier, pleasanter, safer, and less disgraceful means of communication between England and the rest of the world than that which the Channel has offered since Monday last. I cannot but think that your columns of to-day supply eloquent commentaries upon Mr. Stanhope's opposition to my tubular railway. Under the heading, 'Great Gale and Snowstorm,' on page 11 of the *Times* of to-day, vivid descriptions are given of the perils and miseries of those who have attempted this week to get to or from England; the smashing up of the mail steamer is no less vividly portrayed, and this evening we are told that a very strong gale is still blowing at Dover and Folkestone, and that the Channel is 'boisterous and strewn with wreckage.' I have very good reason for believing that, although this state of things and much worse would be submitted to by passengers and the public rather than that any real danger to the country should be incurred, it is a state of things which will not be endured when it is understood that the opposition to a safe and commodious railway is based upon mere voiceless or inarticulate prejudice, or, still worse, upon fears which are purely imaginary, and which people can hardly discuss without a sense of humiliation. My proposed railway offers no secret subterranean and profoundly inaccessible road into this country. It is a way that no regiment could traverse if any British man-of-war, even the smallest, were to say nay, and it is this fact which makes me so confident of speedy success in the enterprise that I shall do all I can to make it easy for the Government and Parliament to treat it fairly and reasonably. Hence my readiness to delay the second reading still longer if that appears desirable."

THE "PYROS" FEED-WATER HEATER AND CIRCULATOR.

THE importance of maintaining at a uniform temperature the shell of a steam boiler has long been fully recognised, and an effectual method of accomplishing this is to employ some means to keep the water in the boiler in constant circulation while getting up steam. The accompanying illustrations show in Figs. 1 and 2 a

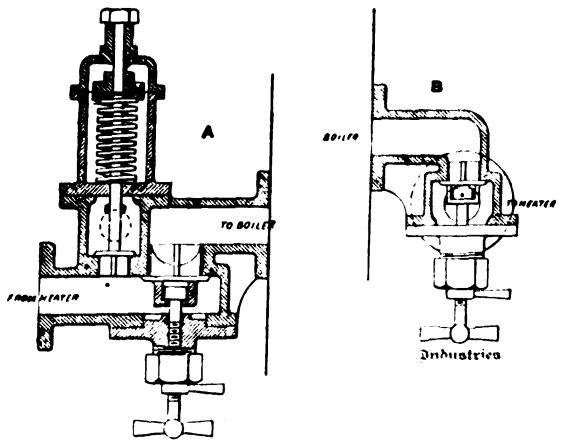

FIG. 3.

front elevation and side sectional elevation of one of the boilers of the s.s. "Cardiganshire," attached to which is an apparatus for circulating the water in the boiler and heating the feed-water prior to its entry, invented by Mr. C. E. Hudson, and called the "Pyros" feed-water heater and circulator. In Fig. 3 is shown a section of the valves marked A B in Figs. 1 and 2. The "Pyros" arrangement simply involves the removal of the furnace fronts and substituting for them heaters of iron or steel of suitable strength for the working pressure of the boiler. These heaters are constructed of a depth equal to the dead plate, and do not interfere in any way with the grate surface. They are fed with water from the bottom or any other portion of the boiler where the circulation is sluggish. The radiant heat from the fires impinges on the back of these heaters, and raises the temperature of the water contained therein. This decreases its density, and causes it to rise through suitable piping and the valve A into the boiler at about the working water level. When the water in the boiler has attained a unifom temperature the circulation ceases, and the heaters then become of use as small auxiliary boilers. It will thus be seen that the action of the apparatus is automatic, and to heat the feed water it is merely necessary to connect the feed valve to one of the heaters. Among the advantages claimed for this apparatus are that in steamships the temperature of the stokeholes is materially decreased, and that the renewals of fire-doors and baffle-plates are reduced to a minimum. We are informed that the apparatus has been at work for a considerable time on the "Cardiganshire," which is of 3,700 tons gross weight, and that from comparisons made with the coal returns of previous voyages a saving of 7 per cent. has resulted. Messrs. A. W. Robertson & Co., engineers and shipbuilders, of Custom House Works, Victoria Docks, London, E., are the makers of this apparatus.

THE CAUSES OF IGNITION OF FIREDAMP.

THE Prussian Firedamp Commission, in its general report, has laid down some general principles which it would be well for us to carefully consider in this country. One of its most important conclusions is to the effect that the use of gunpowder and other slow explosives should be forbidden in fiery mines, and that the use of dynamite and of other explosives should be tolerated, provided that the proportion of firedamp does not pass beyond a danger limit easy to recognise by the aid of a safety lamp. Amongst the rapid explosives, dynamite-guhr appears to be the least secure against inflammation of firedamp and coaldust. Compressed powder, recommended by the French Commission, is highly dangerous in the presence of firedamp. Schultze's powder, of great exploding power, was found to be harmless in the presence of firedamp and coaldust, but inferior qualities do not yield such satisfactory results. Securite and carbonite are both spoken of very favourably by Herr Hasslacher.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 17th March, 1891.

The Iron Market.—Last week the iron market continued very firm at about the same prices as during the previous week. Some orders were given, but there is not as yet a sufficient demand to cause quotations to rise, although fuel was as expensive as formerly. The prices established by the Paris syndicate for the week were as follow:—Best bars, 128s. 6d., and joists, 136s. 6d. per ton. The commercial prices were, for bars 124s., and for joists 132s. 6d. As stated in our last report of the French market, many of the larger contracts lately given out, such as the Cosne and the Briare bridges, which are in steel, have given occupation to steel works, whilst the iron mills are still slack, but affairs are gradually improving for the latter with the recommencement of the building industry. The low state of the English, German, and Belgian markets has also a sinister influence on the French iron trade. A general meeting of rolling-mill owners was held at Paris recently, at which it was proposed to form a committee to control the output of rolling mills and to arrange for an exportation fund. It was also unanimously agreed to raise the tariff of rolled iron and steel 8s. per ton. The latest reports from the Meurthe-et-Moselle district show a decided improvement in the state of the metal trade. The Pont-à-Mousson works have received an order for 16,000 metres of iron pipes of 1 metre diameter, to be delivered within thirteen months. In the North the market is firm without any improvement in prices, and the same may be said of the Loire-et-Rhône district, where the military establishments at Bourges are very busy. In the Haute-Marne orders are beginning to flow in; the wire makers here are especially well occupied. The administration of the "Postes et Télégraphes" has given an order to the Sommevoire works for about 100 tons of castings. In the Gironde the Society of Dyle et Bacalan have taken an order, from the General Society for working the Dutch railways, for rolling stock to the amount of nearly 1,000,000fr.

Coal.—There was no change whatever in the price of coal last week. The increased consumption of fuel by manufactories quite counterbalanced the diminishing demand for domestic purposes. At least two-thirds of the total produce of the French mines has already been bought for future delivery this year. A contract has been entered into by one company to deliver 30,000 tons at Hamburg at 16fr. 25c. per ton.

Copper, Tin, Zinc, and Lead.—Nearly every description of copper fell in price last week. Best Chilian bars were quoted at £57 15s., and ordinary Chilian bars at £55 15s. per ton. Cornwall tin declined 10s. per ton. The other marks showed a slight improvement on the prices of the previous week—viz., Banca, £99 7s. 6d.; Billiton, £96 18s.; and Detroit, £95 10s. per ton. The zinc market was weak, and prices retrogaded to the quotations of three weeks ago. Lead remained firm, without any change in price.

Statistics of the Iron Trade.—The following statistics, taken from documents collected by the Minister of Public Works, gives a comparative view of the output of iron in the Meurthe-et-Moselle, Meuse, and Vosges districts for the past two years:—

		1889. Tons.		1890. Tons.
Meurthe-et-Moselle	Cast iron	943,456	...	1,083,705
"	Wrought iron...	40,734	...	37,838
"	Steel	43,360	...	61,988
Meuse	Cast iron	3,591	...	506
"	Wrought iron...	8,757	...	7,006
"	Steel	8,605	...	7,503
Vosges	Wrought iron...	120	...	210
"	Steel	1,680	...	1,660

BERLIN, 16th March, 1891.

The Metal Trades' Employers' Association.—This association, which held its annual meeting last week, was formed about two years ago as a protection against strikes and unfair demands on the part of the workmen. The threatened demonstration for the 1st May last year caused many firms to join the association, and the unanimous resolution not to grant a holiday on the 1st of May effectually broke the resistance of the men, and only a few moulders absented themselves on that day. Most of these were replaced by other workmen, or locked out for a considerable period, and since then there has been no disturbance of any importance in the metal trades in Berlin. On the 1st of July, 1890, the association founded a central labour agency in Berlin, and all persons desirous of being employed in any of the workshops connected with the association have to apply at the central agency, where their antecedents are carefully examined. In this way leaders of strikes and malcontents are kept away from the workshops of the association.

Electric Lighting at Potsdam.—Potsdam is to be lighted with electricity. The German Continental Gas Company, of Dessau, have purchased large premises in Potsdam for the purpose of erecting a central station.

Locomotives.—It is stated that the Saxon Machine Works of Chemnitz have received an order for the supply of fifty-one locomotives for Java. These works have orders which will occupy them for some considerable time.

Sea Canal.—It has been decided to abandon the projected Berlin-Hamburg Canal, and to promote as much as possible the Berlin-Stettin scheme, which is much shorter and less expensive. The canal is to have a depth of about 24ft. 7in. Upon the completion of the canal from the North Sea to the Baltic, a canal for sea ships from Stettin to Berlin will be of great importance.

Thermo-Electric Battery.—Much interest was manifested in a paper read at a meeting of the "Verein zur Beförderung des Gewerbefleisses," by Mr. Gülcher, upon his experiments with regard to the direct production of electricity from heat. He exhibited his thermo-electric battery, with which he was able to produce an electric power equivalent to 1·08 per cent. of the heat consumed, and hopes to exhibit at Frankfort a battery which will give at least 5 per cent. net effect. He is of opinion that with an economical source of heat, his thermo-electric battery will even excel a dynamo machine. A German patent has been granted for these improvements, and a proof of the interest taken in his patent is the fact that the printed specifications are all sold. Mr. Gülcher has carried on his experiments at the works of Mr. Julius Pintsch, who is well known in connection with his lamps for buoys, lightships, and railway carriages.

The Production of Oxygen.—In a paper upon the production of oxygen, Dr. Elkan has stated that there is not the demand for it in Berlin as in London, because, for scenic effects, the electric light is used on a much more extensive scale in Berlin theatres.

VIENNA, 16th March, 1891.

The Iron Market.—The large decrease in the price of iron in the German market has not hitherto had any influence on the prices in Austria, chiefly by reason of the renewal of the syndicate. A decrease in prices must, however, ensue, as the consumption of iron is not large enough to prevent the accumulation of stocks. Makers of sheet iron are inclined to make concessions, but the prices of bar iron and of iron for constructive purposes are maintained by hopes of a prosperous building season. The regular state of trade maintained by the syndicate was interrupted a fortnight ago by the arrival of three waggons of German bar iron for a Prague manufactory, which had been ordered during the struggle between the German and Austrian works.—An important order for iron water pipes to the amount of 59,000fl. has been placed by the Vienna Municipality. Some orders have also been given in connection with the construction of railways. The Northern Railway is enlarging its Galician lines, and a new railway is to be made in Bosnia, which will connect the centre of that country with the frontier of Dalmatia.

The Coal Market.—The coal market continues animated. During the present month traffic has been very brisk, and large quantities of coal have been sent here. The Bohemian railways have been busily employed in forwarding the coals, which were intended both for home consumption and for export. Last month the Bustichrad railway forwarded 400,000 tons of coal, being 35,000 tons more than the amount forwarded during the previous month.

Electrical Engineering.—The Budapest Electric Railway Company has now been formed, the Count of Szapary being elected chairman. The capital of the company amounts to 3,000,000fl., which is divided into 30,000 shares of 100fl. each. The new company will take over the Budapest City Railway, which now belongs to Messrs. Siemens & Halske, and will enlarge it. This is the sister company of the General Austrian Electricity Company, which was formed a short time ago by Messrs. Siemens & Halske and the Anglo-Austrian Bank.—The International Electricity Company intends to make its provisional central station in Fiume a permanent installation. Up to the present time an output of 10,000 watts has been used for lighting purposes, and about 30,000 watts for the distribution of power. The distribution of power is effected by alternate current motors made by Messrs. Ganz & Co., in Budapest, and is used for the working of four elevators of 10 to 12 effective horse-power. The high tension current is reduced by transformers to a pressure of 50 volts, and the primaries and secondaries are connected together in parallel. Six elevators are to be worked by power supplied by the permanent central station, and more than 100 h.p. is already required for lighting purposes. The harbour authorities are the largest consumers, as they require light for all the piers and the ships lying at anchor.—The electric lighting installations in Austria-Hungary are continually increasing. There are at the present time 185,000 incandescent lamps and 4,000 arc lamps, which are supplied from 1,200 dynamos. Nearly one-third of the total amount is in Vienna, where there are 60,000 incandescent lamps and four central stations. New central stations for Larger Vienna are projected, but much will have to be done before the lighting of Vienna rivals that of London and Paris, with their eighteen and seventeen central stations. The International Compressed Air and Electricity Company has now received a concession, and will at once undertake the construction of a central station.

BRUSSELS, 17th March, 1891.

The Iron Market.—The condition of the iron market is suffering through the uncertain state of the coal market. After a short period, during which prospects seemed to improve, the situation has again become worse, and business is very slack. The state of trade is seriously affected by troubles caused by workmen, who see that wages must necessarily be lowered in the near future. The steel works have a sufficient number of orders to make their position less unsatisfactory than that of the rolling mills. The blast furnaces are feeling the effects of the crisis. The condition of the constructing shops is more favourable, and fine weather will probably increase their activity.

The Coal Market.—It is feared that the revival of trade which was beginning to show itself in the coal market will be adversely affected by recent agitation on the part of workmen. The effects of this agitation are already being felt, and are the more disastrous, as they happen at a time when the crisis which affected the iron market was subsiding by reason of the steadiness of the price of coal. The prospect of a renewed crisis causes sellers to be disinclined to make concessions, and bad news from the Ruhr district is already causing many orders to come here. The market is becoming firmer, and Belgian coal owners will reap some advantage from this circumstance. In the central district prices are especially firm, and in the other districts prices remain at 14fr. to 15fr. for furnace coal, 12fr. to 13fr. for steam coal, 11fr. to 12fr. for small coke, and 18fr. for best coke.

Launch of a Steamer.—Recently a large steamer, built by the Société Cockerill at their Hoboken yard, was successfully launched. The steamer, which is called "Le Prince Baudouin," has a length of 320ft. and a breadth of 40ft.

Glass Works.—A syndicate has been formed to control the sale of glass in all countries. Messrs. Morel & Co. are the only firm which has not joined the syndicate. In view of the present condition of the American glass trade, the formation of the syndicate should be advantageous for Belgian glass works.

Telephones.—An extension of the telephone system towards the north of France has been projected. A connection is to be made between the telephone lines of Lille-Roubaix and those of Tournai and Courtrai. The frequent correspondence between Belgian and French towns towards the frontier makes such a connection quite indispensable.

DÜSSELDORF, 17th March, 1891.

The Iron Market.—This market is quiet, and business is suffering in consequence of the high prices of fuel.

The Coal Market.—The opinion that no general strike of the coal miners will occur this spring gains more and more ground. In the past two years wages have been considerably increased, and the feeling that in the case of a general strike the miners would find against them not only the coalowners, but also the Government and public opinion, has made a deep impression on the bulk of the miners. The demand for all kinds of coal and coke continues to be a very strong one, but the fact that the tender of German coal for the Amsterdam gasworks has been beaten by an English offer has made a bad impression. The quantity required amounts to 81,000 tons, and it is feared that this diminution in the amount which in previous years has been shipped through the Ruhrort Harbour will sensibly affect the Rhine traffic. The fact has been registered on the Berlin Stock Exchange by a downward movement in most of the coal shares.

Desulphurising Process.—The steel works at Hoerde have introduced most successfully a new process for desulphurising pig iron, and most of the large steel works are applying for licences.

The Glass Industry.—The Gerreshein Glass Works, which have a yearly output of about 80 millions of bottles, have paid a dividend of 9 per cent. A Belgian company has just opened a large manufactory for making plate glass at Ratingen, near this town.

AMSTERDAM, 16th March, 1891.

Steamers.—Messrs. Meyer & Co., steamship owners and shipping agents at Amsterdam, the representatives of Holt's Company (Liverpool), whose project of starting a new line of steamers between Holland and the Dutch East Indies has been mentioned in a previous letter, will form a new steamship company for the purpose, which will take over whatever rights and contracts the former may acquire in the course of their present negotiations with the Home Government.

Co-operative Building at the Hague.—A committee has been formed at a public meeting, held at the Hague, for the purpose of founding a small company with the object of building dwellings for the working classes upon the co-operative system.

The Queenborough Route to the Continent.—The directors of the Zeeland Steamship Company at Flushing, whose boats have kept up the Channel service between Queenborough and Flushing with wonderful regularity during the recent storms, are fully alive to the necessity of increasing traffic facilities so as to cope with the severe competition of the Dover and Folkestone routes. The day service is again to be accelerated, and to be brought into closer connection with the continental fast trains. A new English guidebook, fully illustrated, is also to be issued shortly, showing the many advantages of the Flushing route. The Zeeland Company will also start a bi-weekly steamship service between Flushing and Hull, for merchandise in the first instance, and the service is afterwards to be extended to passengers, should occasion demand it.

Digitized by Google

For that purpose, a new company is to be formed, called the Zeelandic Steamship Company, which will be under the same management as the Zeeland Steamship Company, and will acquire new steamers for the intended service.

Fiscal Union between Holland and her Indian Colonies.—The plan which existed to form a fiscal union between Holland and the Dutch Indian Empire has been abandoned for the present, the Dutch Indian Government intimating that such a union would involve serious losses to the Dutch Indian Treasury, which it could not well bear under present circumstances.

STOCKHOLM, 14th March, 1891.

New Industry in Sweden.—The chemical works of Mr. S. Barnekow, in Sweden, are about to be extended, so as also to comprise the manufacture of carbons for electric arc lamps and for dry cells. The works will be completed in the course of the summer, and will be fitted with the most approved machinery. It is intended to supply the export trade as well as the home market.

The Bollnäs Silver Mines.—The work at the new silver mines at Bollnäs is being steadily proceeded with. So far, the findings have only been of moderate quality, but it is expected that the ore will improve as the workings are carried deeper. A similar mine is to be found at Lenninge, but it has not been worked since the beginning of the century, when the work was discontinued for want of money.

Export of Charcoal.—It seems likely that charcoal will find a market for export. There are inquiries for large quantities for England, and the Swedish Export Society favours such export. It might, however, prove a dangerous policy to raise the price of this necessary commodity by creating an export trade, as it might place obstacles in the way of the production of iron, which is by no means too remunerative.

The Swedish-Norwegian Railway Company.—The sale of this company's property in Sweden, which consists of the railway from Lulea to Gellivara, with the harbour accommodation at Lulea, to the Swedish Government, has now been definitely settled.

New Curtain Manufactory.—The active movement in the textile industry continues, and a new company has been formed for the erection of a curtain manufactory in Malmö. The style of the new concern is the "Aktiebolaget Svenske Gardinfabriken."

The Gellivara Company.—This company has now been reconstructed, the Stockholm banks having been paid through the sale of the Munksund and the Pitea works. The anticipated collapse of the company has thus been averted, and their property will ultimately prove a valuable one, especially since the Swedish Government has bought the Gellivara-Lulea railway.

CHRISTIANIA, 14th March, 1891.

New Steamer.—The Moss Engineering Company has just secured a contract from Captain I. Henrichsen for the building of a new steamer for the Vestlandske Godsdampskibsselskab. The steamer is to be ready in September, and is intended for the Christiania and Bergen trade.

Difficult Submarine Work.—An interesting and somewhat difficult work has been done at Smörviken, where three water pipes have been laid down into the Mjösen lake. These pipes, of which one is a 10in. and the two others 5in. pipes, are intended to furnish the milk condensing factory at Toten with fresh and clean water. The pipes have been laid several metres below the bottom of the lake, which it was found necessary to lay dry at the place in question. Divers were employed in carrying out the work.

Raising of a Steamer.—The steamer "Egil," which foundered at Sandtorv, has been raised by the "Nordenfjeldske" Salvage Company. This company has, since its formation in 1871, raised fifty-five vessels, thirty-one of which were steamers.

COPENHAGEN, 14th March, 1891.

Railway Works at Elsinore.—The important railway works at Elsinore, which have been rendered necessary by the steamer ferry traffic, which is to be carried on between Elsinore and Helsingborg, are now approaching completion. One of the more interesting features is a viaduct across the Strandoei. This viaduct consists of one single granite arch 24ft. broad, and with a span of 75ft. The arch is very flat and thin, a result which has been made possible by the insertion of lead between the granite. The removal of the scaffolding took place a few days ago, and was a delicate operation. The scaffolding rested on about a hundred iron buckets filled with sand. In order to lower it an equal quantity of sand was let out of each bucket through holes at the bottom, and the arch gradually stood free of its scaffolding.

The Copenhagen Steam Tramways.—The steam tramways between Copenhagen and Kloenpenborg, a distance of about six miles, are by no means a lucrative undertaking. Last year shows a surplus of 1,972kr., the receipts being 186,188kr. and the expenses 184,216kr. This is, however, an improvement upon the previous year's balance sheet, which showed a loss of 36,885kr.

The Copenhagen Tramway Company.—The report for last year shows the receipts were 630,017kr., and the expenses 536,054kr., leaving profits of 93,963kr., which will give the shareholders a dividend of 10s. per share. The repairs of tramcars have amounted to 34,922kr., the permanent road has entailed an expenditure of 56,000kr., and the horses one of 338,992kr.

MADRID, 16th March, 1891.

Scrap Iron.—The development of the steel industry at Bilbao and Asturias is causing a large demand for scrap iron. The supply is not at present equal to the demand, and scrap iron is eagerly bought in the centre of the country for transport to Bilbao. This state of affairs has upset the scrap iron industry at Barcelona and Sevilla, as these works are now unable to obtain a supply of scrap iron from the small districts in the neighbourhood. The ore process or the new Adam's process must be introduced in Spain shortly, as the manufacture of steel is to be increased.

Siemens Improved Furnaces.—It seems likely that these furnaces will be introduced very largely in Spain. Arrangements have been made to use these furnaces both for heating and puddling, and some ironmasters are intending to apply them to the manufacture of steel.

The Death Rate of Madrid.—The returns for last year show that the death rate of the capital is now nearly 45 per 1,000. Much comment is being made on the unfavourable nature of these returns, but it seems unlikely that any definite action will be taken. The want of a proper system of sanitary engineering is largely responsible for the result, and it must be added that the cost of food in Madrid is very high, and that wages are not high in proportion.

Long Distance Telephones.—A plan is now being considered by the Spanish Government for the establishment of a complete system of long distance telephone lines, such as does not yet exist in any country. The scheme consists in putting Madrid into communication with the 49 provincial capitals. The central office will be at Madrid, and the provincial capitals will thus obtain communication with one another. It would seem advisable that the preliminary step of placing the larger town in connection with Madrid should first be adopted. Capitalists should hesitate before investing their money in a concern which may turn out to be unsuccessful like the tobacco monopoly. With reference to this scheme, it seems important that uniformity of time should be established throughout the country, so that appointments may be made at fixed hours between the inhabitants of distant towns.

ROME, 16th March, 1891.

International Exhibition of the Building Industries at Padua.—La Société d'Hygiène of the town and province of Padua, in Italy, is organisising an International Exhibition of the Building Industries, to be held during the present year. The object of the Exhibition is a humanitarian one—namely, to arrive at a system of perfect hygienic construction in buildings, and more especially in workmen's habitations. The Exhibition will be held during the months of May and June next.

Exhibition of Implements Used in Wine Production.—It is announced by the Italian Ministry of Agriculture that there will be an International Exhibition and trial of implements used in the production of wine at Portici, next September. Intending competitors can receive full particulars by applying to Mr. Guido Rossati, Regia Stazione Enotechnica Italiana, 31, Old Jewry, London, E.C.

The Production and Consumption of Fuel.—From recent returns issued by the Government, it appears that whilst in 1871 Italy produced 80,336 tons of lignite and imported 791,389 tons of coals from abroad, in 1888 the production of lignite was raised to 366,794 tons, and the importation of coals to 3,872,905 tons. In addition to the lignite the country also produced, in 1888, 30,000 tons of turf and 490,000 tons of bricks. The total quantity of fuel used in 1889 amounted to nearly 5,000,000 tons. Of this amount steam engines for industrial and agricultural purposes used 1,300,000 tons, or 26·44 per cent.; lime kilns, glass works, and foundries, 1,300,000 tons, or 26·44 per cent.; locomotives for railways and tramways, 750,000 tons, or 15·25 per cent.; gas and electric lighting, 850,000 tons, or 17·29 per cent.; shipping companies, 313,565 tons, or 6·38 per cent.; coal used for household purposes, 330,307 tons, or 6·71 per cent. It should be added that in Italy there are also many hydraulic engines, with a total output of 600,000 horse-power.

NEW YORK, 7th March, 1891.

Gas from Wood.—The Attleboro Gas Company has introduced in its works a Ramsdell apparatus for the manufacture of wood and oil gas. It is claimed that gas from wood is the most healthful produced by any process, and that it possesses a higher degree of illuminating power than any gas made. It is said that one cord of dry wood and 300 gallons of crude Lima oil will produce 60,000 to 80,000 cubic feet of gas, of 20 to 30 candle-power, with a residue of nearly two barrels of fine tar and and sixty-five bushels of merchantable charcoal. The gas is manufactured in retorts in from two to three hours. By this process, the gas, according to the *Manufacturers' Gazette*, can stand much colder weather without condensing or stratifying, being superheated afterward as near a fixed gas as coal gas. This gas is made in one operation, and only one fire is required to make a perfect fixed gas. The same retorts are used as in making coal gas, with a mixer and a superheater attached. The wood used is maple. When the gas has been extracted, the wood is carbonised, leaving a fine quality of charcoal. With the wood, Lima oil is used in the manufacture to produce the required candle-power. The patentee is Mr. George Ramsdell, who has been fifteen years in completing the process.

The East River Tunnel.—The East River Tunnel, from Atlantic Avenue, Brooklyn, to the foot of Whitehall Street, New York, will be commenced about the 1st of April. Most careful rock borings have been made, the plans are completed, and tenders are now being considered. Mr. Charles M. Jacobs, M.Am.Inst.C.E., is the chief engineer. This is a part of Mr. Austin Corbin's project for rapid transit in New York.

A New Station Indicator.—A new station indicator for railway carriages, which is intended as an improvement on the prevailing system of having the names of each station announced by the guard of the train, has been brought out by the Allison Company, of Montreal, Canada. The Allison indicator is very simple in construction, and is operated by the guard of the train. It has already been fitted with success to the first-class carriages running between Montreal and Toronto.

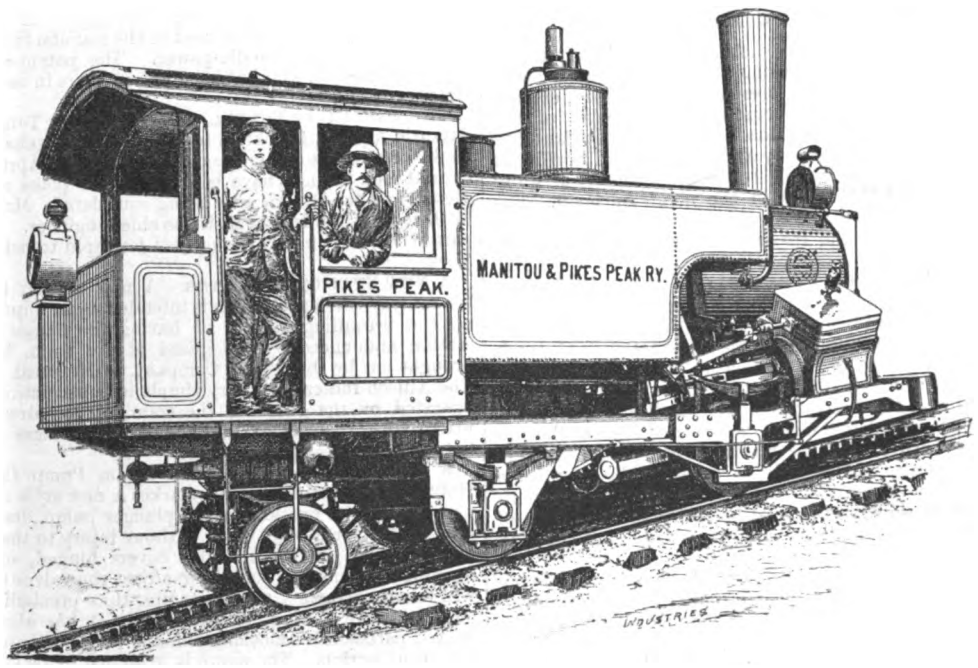
A New Pump.—The Deane Steam Pump Company, Holyoke, are putting on the market a new style of sinker pump. It is an outside packed plunger pump, designed to pump gritty or muddy water without injury to the mechanism. It has all the movable covers hinged, so that in opening the pump to pack it or adjust the valves the parts will remain attached to the pumps, thus precluding their getting lost or falling into the shaft. It has also an improved patent valve motion, which is very simple and positive in its action. The pump is arranged to be suspended from a derrick within the shaft, during the process of sinking the shaft. Several of these pumps have been sold to mines in Colorado, and are stated to be giving perfect satisfaction.

PHILADELPHIA, 6th March, 1891.

New Wire Plant.—The Western agent of Messrs. Washburn & Morn, the barbed-wire manufacturers of Massachusetts, have purchased for that company 800 acres of land adjoining the town of Waukegan, a few miles north of Chicago. As soon as the season opens that company intends to erect a large plant for carrying on their manufacturing business in the West.

St. Louis Improvements.—The new Merchants' Bridge Terminal Railroad Company has decided to erect a large depôt at a cost of nearly $500,000, and to make other improvements at a further cost of about $15,000,000. The depôt will have a frontage on Broadway, and will be 800ft. long. The ordinance providing for these improvements is now in the mayor's hands, and will be operative in a few days.

Technical Education.—A new manual training school was recently opened in Philadelphia, in which iron work has a prominent place. Adjoining the principal class-room is the iron work department. The furniture in this room consists of two rows of benches, with twenty-four vices, and beside each vice lies a complete set of tools. In one corner of the room is a forge for tempering tools and for forging. The only expense for each boy is the furnishing of two aprons and a set of mathematical instruments.



Reduced Freights for Iron and Steel.—The reduction in iron and steel rates decided on a few days ago by the Central Traffic Association will benefit Pittsburgh manufacturers by nearly $50,000 a month. Ordinarily a reduction is obtained only by continued demands, but the Pittsburgh people are indebted to the furnace proprietors in the Mahoning and Shenango Valleys for the present one. Complaint has been made for over a year that the competition of Southern furnaces, when aided by the low rates at which their product was carried to market, was too severe. They demanded lower rates on manufactured articles, pig iron, and coke. This reduction is the first the railroads have ever made in aid of the furnace proprietors. It will particularly benefit the mill proprietors by enabling them to market their iron cheaper, and keep the custom, which has been seriously menaced by Western rolling mill and steel works. Twenty-three of the furnaces which are now idle in these districts are likely to be blown in within the next few days.

Mining Statistics.—The inspector of the Fifth Anthracite District has forwarded his report for 1890 to the Secretary of the Interior at Harrisburg. There were 66 fatal accidents in the district during the year, an increase of 6 over the previous year. Of these, 6 were due to the men falling down the slopes or shafts, 22 to falls of coal, 14 were due to men being crushed by mine cars, 3 were caused by explosion of fire-damp, 4 by suffocation by gas, and the remainder by minor accidents. The amount of coal produced for each fatal accident varied from 52,200 tons, in the mines of Messrs. Leutz, Lilly, & Co., to 137,807 tons, in the mines worked by individual operators. The number of miners employed in the district was 19,150, producing 6,299,821 tons of coal, or 321 tons for each employé.

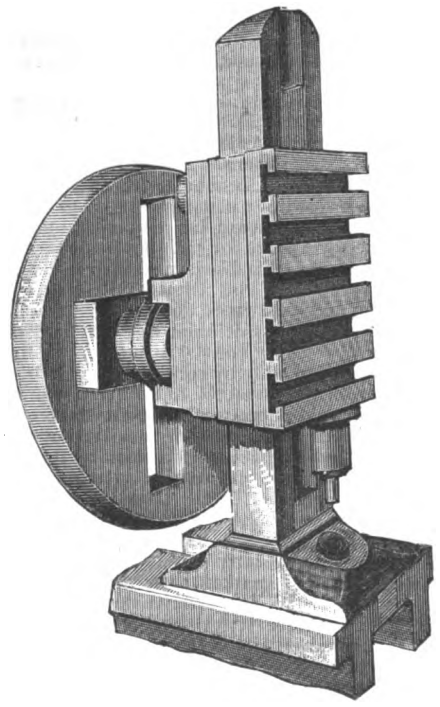
THE "ABT" LOCOMOTIVE



For the Manitou and Pike's Peak Railway, Colorado, U.S.A.

General View of Locomotive.

AN IMPROVED LATHE ATTACHMENT.

The accompanying illustration represents an appliance for attaching to lathes and other similar tools for obtaining a vertical reciprocal motion. It is made by Mr. F. M. Rogers, 21, Finsbury Pavement, London, E.C. The action of the apparatus is simple, and will be understood from the illustration. A vertical standard, which can be bolted to the lathe bed, has free to slide upon it a grooved face plate. This can be moved up and down by means of a roller or guide block mounted upon a pin

bolted to the chuck plate of the lathe. The pin is free to move backwards and forwards in the roller path formed on the back of the slide, the length of stroke, of course, depending upon the distance between the pin and the mandrel centre. The appliance, which is likely to be found particularly useful in small shops, can be used for a variety of purposes. By placing a cutting tool in the slide rest of the lathe, and feeding either by hand or automatically, a piece of work fixed to the reciprocating plate can be either planed or shaped, or the appliance could be used for punching or shearing if desired.

THE "ABT" LOCOMOTIVE.

The illustration given above represents a perspective view of the "Abt" locomotive, three of which have been built by the Baldwin Locomotive Works, of Philadelphia, U.S.A., for working the traffic on the Manitou and Pike's Peak Railway, which was opened last autumn. This railway, which extends from Manitou, at an elevation of 6,563·3ft., to Pike's Peak, 14,115·3ft. above sea level, and is nine miles long, is worked on the "Abt" cog-wheel system. Each locomotive weighs 26 tons, and has a capacity for 600 gallons of water, carried in saddle tanks, and 1¼ tons of coal carried at the rear of the engine. The cylinders are 17in. diameter by 20in. stroke. The main frame is of the bar type at the front and of channel iron at the rear, the back horn-block being made of a plate riveted to the channel-iron frame. The rear truck swings on a radius bar. The power is transmitted by a main toothed drum gearing with back sets of pinions; a forward set of pinions being driven by connecting rods from the middle set of pinions. The back sets furnish the greater portion of the power during the ascent, the forward set being used principally when applying the brake. In the descent the engine cylinders are used as air compressors, and can be controlled at will—thereby regulating the speed of the train. The front sets of pinions are attached to a novel kind of steam brake, by which they can be locked instantly, and a hand brake is fitted to the back pinions. The cars are 43ft. long, 8½ft. wide, and are capable of seating 50 persons. The maximum and minimum speeds of the trains are eight and three miles per hour respectively, and the whole journey is completed in one hour and forty-five minutes. Our illustration is taken from our American contemporary, the *Railroad Gazette*.

THE INSTITUTE OF MARINE ENGINEERS.

A meeting of this Institute was held on the 10th inst. and presided over by Mr. F. W. Wymer, when a paper on "An Improved Water Cooler," prepared by Mr. Cooper (a member located at Bombay), was read, in the absence of the author, by Mr. W. W. Wilson. The author briefly referred to the various methods in use for cooling water and for the manufacture of freezing mixtures. The special apparatus was then described as follows:—A barrel sufficiently tight to hold water is obtained. On it is placed a drum of sufficient strength to withstand atmospheric pressure on the outside. The inside of the drum is connected in any convenient way with the condenser by means of a pipe. Another pipe of decreasing diameter is also connected to and coiled around the drum, the smallest diameter being connected to the atmospheric by means of an adjustable cock or valve. The space between the drum and the barrel inside is then filled with water to a convenient level, and the water cooler is complete ready for action. The principle involved is the expansion of the air in its course through the increasing diameter of pipe, thence into the drum, which, being connected to the condenser, is equivalent to expanding the air ultimately into a vacuum. The efficiency of the cooler is further increased by the addition of drops of water, which are allowed to enter with the air into the small end of the pipe.

A discussion followed the reading of the paper.

The honorary secretary intimated that the next meeting would be held on the 24th inst., when possibly Mr. Manuel would be able to attend and read a paper. It is expected also that specimens of weldless steel chain, showing the different processes of manufacture, would be exhibited and explained by a representative of the London agent of the manufacturer.

THE MANCHESTER SHIP CANAL.

III.

We publish on page 276 two views of the locks at Irlam. Fig. 5 shows the locks with the sluices in the foreground, and Fig. 6 shows the formation of the lock bottom. In later issues we shall give further views of this very important work.

LEEDS ASSOCIATION OF ENGINEERS.

At a meeting of this Association, held on the 10th inst., the President (Mr. A. Atkinson) gave an interesting account of his visit to the anniversary gathering of the Birmingham Association. He said that during his stay he, along with the other delegates, visited the electric tramway installation, and Mr. Pritchard, the engineer, explained the working of the system. The engines, boilers, and dynamos are in duplicate. Each boiler is capable of generating steam for one engine, each engine delivering 100 horse-power on the fly-wheel. The two boilers are of steel, multitubular, of the economic safety type, 12ft. 6in. long and 7ft. 6in. diameter. The engines are horizontal, of the receiver type, non-condensing, having cylinders 12¾in. and 20in. in diameter, with a stroke of 24in. The dynamos, two in number, are in the same room, each driven with leather-linked belts 16in. wide. The dynamos are of the Elwell-Parker continuous-current type, shunt wound, each giving 120 volts and 500 amperes at an approximate speed of 540 revolutions per minute, and doing the whole of the work of charging the accumulators for twelve cars, and also lighting up the depôt and supplying an eight-unit motor, which drives the machine tools, &c. The cars will each carry fifty passengers, and can travel at eight miles an hour. The motors are also of the Elwell-Parker type, running at 140 revolutions per minute, but a velocity of 700 revolutions is required to maintain a travelling speed of eight miles an hour. The visitors journeyed some distance on the cars, which they found to run very steadily, the chief objection being the noise, which might be lessened by more suitable gearing. The overhead system has been passed by in favour of the storage system, for the sake of appearance. The latter had, however, the disadvantage of very heavy cars, which came to a gross weight of 10 or 12 tons. Mr. Atkinson then described the wire rope or cable system of tramways, which they next inspected. This system is being worked over a course of three miles, in two sections of a mile and a half each, the engines and boilers, which are in duplicate, being placed at the lowest point in the gradients, between the two sections. For a distance of over three miles the electrical system was doubtless the most economical; but for shorter distances the wire rope or cable system was the best. The overhead method of propelling the cars, as proposed for Leeds, would be cheaper in first cost, and far cheaper in working than the accumulator or storage system; but the under-grooving system was the best of all. Afterwards they visited the works of Messrs. Tangye, where the clean and good castings seen were especially admired. Mr. Atkinson described the method in use there of distributing and checking the work, which was done by a system of cards. The delegates were then driven to the house of Mr. George Tangye, which had once been the home of James Watt, and which contains the room in which he used to work, just as he left it. On the 26th inst. Mr. Henry McLaren will read a paper on "Boiler and Engine Tests."

SHIPBUILDING NOTES.

On the 24th ult. the last of the three protected cruisers was launched at the yard of Messrs. James & George Thomson. The "Tribune" is similar to the two sister ships, and her length is 300ft.; breadth, 43ft.; depth, to upper deck, 22ft. 9in.; and displacement, 3,400 tons. She is fitted with vertical inverted triple-expansion engines. The speed expected to be attained is 18 to 20 miles per hour. The armament will be two 6in., and six 4·7in. quick-firing guns, eight quick-firing 6-pounder Hotchkiss guns, one 3-pounder Hotchkiss gun, four 5-barrelled Nordenfeldt guns, and four torpedo tubes. An arched steel deck extends from stem to stern. There is a cellular double bottom, and the hull is divided into compartments by numerous bulkheads.

On the 24th ult. Messrs. Ropner & Son launched at Stockton-on-Tees the steel screw steamer "Lammermoor," of the following dimensions:—Length, over all, 324ft.; breadth, 40ft. 6in.; depth, moulded, 23ft. 7in. She will be classed 100 A1 at Lloyd's, and carry 4,350 tons deadweight on Lloyd's summer freeboard. The vessel has a cellular bottom for water ballast, and is built on the web-frame principle. Her engines are by Messrs. Blair & Co., Limited, on their improved triple-expansion principle, of 1,200 i.h.p., with two large steel boilers working at 160lb. pressure. The steamer has been built for Messrs. W. Runciman & Co., of South Shields.

On the 24th ult. Messrs. Sir Raylton Dixon & Co. launched from their Cleveland Dockyard, Middlesbrough, the steel screw steamer "Pembridge," built to the order of Messrs. J. Temperley & Co., of Newcastle and London, for the Temperley Steam Shipping Company, Limited. This vessel is built with web frames, and has long full poop, raised deck forward and forecastle. Her dimensions are:—Length, over all, 323ft. 6in.; breadth, 41ft.; depth, moulded, 23ft. 1½in., with a carrying capacity of about 4,300 tons. Her machinery will be fitted by Messrs. T. Richardson & Sons, Hartlepool, having cylinders 23in., 38in., and 62in., by 42in. stroke.

On the 24th ult. Messrs. Edward Withy & Co. launched from their yard at Hartlepool a large steel screw steamer, the "Calcutta City," built to the order of Mr. C. Furness, M.P., West Hartlepool. She is a fine type of a modern cargo boat, measuring over 320ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at Lloyd's. The holds are fitted with iron grain divisions and wood cargo battens; all decks, deck erections, skylights, bulwarks, and bulkheads are constructed of steel and iron. Cellular bottoms are fitted fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. She will be fitted with triple-expansion engines by Messrs. Richardson & Sons, Hartlepool.

On the 25th ult. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington Quay-on-Tyne, a steel screw steamer, "Cape Comorin," of the following dimensions, viz.:—Length, 300ft.; breadth, 38ft. 8in.; depth, 23ft. 2in., and to class 100 A1 at Lloyd's on the partial awning deck rule. This vessel has water ballast fitted right fore and aft on the cellular system, and is also fitted with all modern improvements for the rapid loading and discharging of cargo. The engines, which are to be supplied by the North Eastern Marine Engineering Company, Limited, are of the triple-expansion type, having cylinders 23in., 38in., and 63in., with 42in. stroke, and working at a pressure of 150lb.

Notices of Meetings.

THIS WEEK.

Physical Society.—Friday, March 20th. Papers to be read: "The Theory of Dissociation into Ions and Its Consequences," by Mr. S. U. Pickering, F.R.S.; "Some Points in Electrolysis," by Mr. J. Swinburne; "The Variation of Surface Tension with Temperature," by Mr. A. L. Selby; "On Magnetic Proof Pieces and Proof Planes," by Professor S. P. Thompson.

Junior Engineering Society.—Friday, March 20th, at 8 p.m. Paper to be read: "Iron, from the Ore to the Casting," by Mr. H. J. Young.

Sanitary Institute.—Friday, March 20th, at 8 p.m. Paper to be read: "Sanitary Law, English, Scotch, and Irish; General Enactments; Public Health Act, 1875; Model Bye Laws," by Mr. A Wynter Blyth.

Balloon Society.—Friday, March 20th, at 8 p.m. Paper to be read: "The Factories and Workshops Bills," by Miss E. Lupton.

Royal Institution.—Saturday, March 21st, at 3 p.m. Lecture VI., on "The Forces of Cohesion," by Lord Rayleigh, F.R.S.

South Staffordshire Institute of Iron and Steel Works Managers.—Saturday, March 21st, at 7 p.m. Papers to be read: "Smoke Prevention and Gaseous Fuel," by Mr. J. W. Sheel; "The Manufacture of Basic Steel by the Open-hearth Process, with Special Reference to Some of the Furnaces Employed," by Mr. G. A. Millward.

NEXT WEEK.

Society of Arts.—Monday, March 23rd, at 8 p.m. Cantor Lecture III., on "Photographic Chemistry," by Professor R. Meldola, F.R.S.

Royal Institute of British Architects.—Monday, March 23rd, at 8 p.m. Sessional meeting.

North East Coast Institution of Engineers and Shipbuilders.—Monday, March 23rd, at 7.30 p.m. Paper to be read: "Electrical Engineering, with Special Reference to Electric Lighting," by Mr. W. C. Mountain. Graduates' Section, Monday, March 23rd, at 7.45 p.m. Paper to be read: "The Development of the Screw Propeller," by Mr. R. L. Gaine.

Institution of Civil Engineers.—Tuesday, March 24th, at 8 p.m. Ordinary meeting. Paper to be read and discussed: "On the Reception and Storage of Petroleum Oil in Bulk," by Mr. W. T. H. Carrington, M.Inst.C.E.

Society of Architects.—Tuesday, March 24th, at 7.30 p.m. Ordinary meeting.

Sanitary Institute.—Tuesday, March 24th, at 8 p.m. Paper to be read: "Sanitary Laws and Regulations Governing the Metropolis," by Mr. A. Wynter Blyth.

Chemical Society.—Wednesday, March 25th, at 8 p.m. Anniversary meeting.

PRICES CURRENT, 18th March, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

METALS.

Spelter: Ordinary	£25	0	0	to	25	5	0
Copper: British Cakes and Ingots	56	10	0	„	57	0	0
„ Chili Bars, G.O.B.'s	52	0	0	„	52	5	0
„ Other sorts, G.M.B.'s (equal to Chili Bars)	52	0	0	„	52	5	0
„ Manufactured (strong)	65	0	0		.....		
Lead: Common Pig	13	10	0	„	13	15	0
„ English Sheet	14	5	0	„	14	10	0
Tin: Straits	90	2	6	„	90	10	0
„ Australian	90	7	6	„	90	15	0
„ English Ingots	94	10	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: Steady, with limited business. Chili bars have advanced, and it is noticeable that during the past week the margin between cash and forward metal disappeared, owing to the scarcity of "spot" offering. Three months' quotations are, however, again a shade dearer, prices to-day being £52 to £52 5s. cash, and £52 to £52 7s. 6d. three months. Manufactured £65, "strong."

Tin continues exceptionally steady, values to-day being exactly as on the 11th, the date of our last report.

Lead: Slightly weaker, with small demand.

Spelter is a shade easier, owing to increasing slackness in the galvanising trade.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Many complaints are now being made of the dulness of the chemical trade. There is a very slow demand for carbolic acids, but prices remain steady. Benzoles are quiet. Creosote moderately active. Sulphate of ammonia has advanced, and is tending further upwards. Sulphate of copper is easing slightly. All lead salts are steady.

The first issue of "*The Health Record*, an Irish Journal of Sanitary Science," has recently appeared. The journal will contain articles dealing with the medical, legal, and engineering aspects of sanitary science. In the present issue there will be found articles by well-known writers on the storage of water, the prevention of consumption, the public health and the necessity for the registration of plumbers, and electricity as applied for sanitary purposes.

We have received from Mr. Frederic Nell, engineer, 16, Mark Lane, London, E.C., a well-illustrated catalogue of the "Victor" turbine. Since the publication of the last catalogue several improvements in details of construction have been made, which are described in the catalogue. A table is given showing the scientific tests to which the Victor turbine has been subjected, and there are also tables giving the horse-power, cubic feet required, and revolutions per minute for each size of the turbine, with different heads of water.

HOME INDUSTRIES.

LONDON, 19th March, 1891.

THE MONEY MARKET.—Money has been somewhat scarce this week, the issue of a quantity of Treasury Bills before the maturing paper which they replaced was due having taken a considerable sum off the market. Rates for short loans have consequently been fairly firm, but discount rates have not been similarly affected owing to a scarcity of commercial paper. The gold movement has been on the whole in favour of the Bank, but a substantial sum has been taken for the River Plate. The stock markets continue featureless and uninteresting. The buying of Consols by the Government and the banks, which attracted some attention at the close of last week, has ceased. Foreign Government securities have been firm, and the financial crisis in Paris has had very little effect on international stocks, its influence being purely local. In home railways the only activity has been in the Scottish stocks, and the unfavourable character of the half-yearly reports, just issued, of the Caledonian and North British, has caused a good deal of selling. American railways have shown a slightly improving tendency, but it has been rather of a halting and uncertain description. In Canadian railways there has been little movement. After remaining stationary for nearly a week, silver has fallen in price again, and the securities dependent on it have declined also. In mining and industrial descriptions there has been no marked movement or tendency.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—On the 16th inst. a general meeting of the Congress was held at the rooms of the British Medical Society, 20, Hanover Square, at which the Prince of Wales presided. Sir Douglas Galton, president of the organising committee, stated that at the sixth International Congress, which was held in Vienna in 1887, it was resolved to hold the seventh congress in London during the present year. The congress is organised in two divisions and ten sections, viz.:—Division I., Hygiene, in nine sections (1, Preventive Medicine; 2, Bacteriology; 3, Relation of the Diseases of Animals to those of Man; 4, Hygiene of Infancy and Childhood; 5, Chemistry and Physics in relation to Hygiene; 6, Architecture in relation to Hygiene; 7, Engineering in relation to Hygiene; 8, Naval and Military Hygiene; 9, State Hygiene). Division II., Demography (Demography, Health, Statistics, and Industrial Hygiene). The congress is to be opened on the 10th of August by an inaugural meeting at the St. James's Hall, at which the Prince of Wales will preside, and the meetings of the various sections will take place on the five following days at Burlington House. Invitations have been sent to foreign Governments, to India and the Colonies, and to the various County Councils in the United Kingdom. A sum of between £5,000 and £6,000 will be required for the organisation of the congress and for the publication of the transactions.

EXHIBITION OF PRINTING APPLIANCES.—On the 16th inst. an exhibition of appliances connected with the printing and paper trades was opened at the Agricultural Hall, Islington, and will remain open till the end of this month. Some of the exhibitors had not completed their preparations at the time of opening, but the Exhibition seems to be a fairly representative one. Various appliances used in printing and lithographing are shown by some of the leading firms engaged in those trades, and many recent inventions are exhibited. Machines for multi-colour printing, automatic feeding machines, lithographic processes, and type founding are to be shown in operation during the holding of the Exhibition.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—An exhibition of collotype printing, a process in which photography plays the part of the lithographic artist and a sensitised gelatine film that of the lithographic stone, will be on view daily till the 14th of April, between 2 p.m. and 9 p.m., at the rooms of the Photographic Society, 50, Great Russell Street, Bloomsbury. Admission may be obtained on presentation of a visiting card.

THE JUNIOR ENGINEERING SOCIETY.—A numerously attended excursion of this Society took place on the 7th inst., when the boiler works of Messrs. Maudslay, Sons, & Field, at East Greenwich, were visited. The chief points of interest were a double-plate heating furnace; a hydraulic flanging machine capable of operating upon plates 1¼in. thick; powerful fixed hydraulic riveters, the largest of which has a 12ft. gap; a pair of horizontal engines for driving the machinery; and the hydraulic and electric light plants. The boilers in course of construction included a set of five for H.M.S. "Spartan"; a set of eight for H.M.S. "Royal Arthur," the vessel recently launched at Portsmouth; a similar set for H.M.S. "Theseus"; and sixteen for the Imperial Russian Government cruiser "George the Conqueror," now being built in Russia.

THE LATE CAPTAIN DANIEL PENDER, R.N.—Captain Daniel Pender, R.N., assistant hydrographer to the Admiralty, died on the 12th inst. During ten years he was employed on surveying work in the Pacific, of which he had an extensive knowledge. After leaving the Pacific station, he received the appointment of naval assistant in the Hydrographic Department of the Admiralty, and afterwards became chief naval assistant and assistant hydrographer.

THE BALLOON SOCIETY.—At a meeting of the Balloon Society, on the 13th inst., Mr. Lennox Brown being in the chair, Mr. Thomas Christy, F.L.S., read a paper on "Improvements in Surgical Dressings and Waterproof Materials." After referring to the fact that both oiled silk and gutta-percha tissue have been discarded by the Governments of England, France, the United States Denmark, and Norway, in consequence of their impracticability, the author proceeded to describe the new material, which has been named "Christia," and is made by a process of felting the pure fibre of the Manilla hemp. The material is a membrane-like tissue, very light and strong, impermeable to water, spirits of all kinds oils, and acids. It is made neutral, so that it can be rendered antiseptic with any desired medicament. It will stand tropical heat and Arctic cold without being in the least injuriously affected by the changes. It is particularly adapted for India and other hot climates, where gutta-percha tissue and oiled silk becomes in a short time amalgamated together to such an extent as to be not only useless to the surgeon, but injurious to anything with which it comes in contact. Another advantage is that it is only about half the price of oiled silk.

MANCHESTER, 19th March, 1891.

THE AIR OF MANCHESTER.—An exhaustive inquiry into the character of the air in Manchester, especially during the prevalence of fog, has been carried out by Drs. G. H. Bailey and J. B. Cohen and Mr. P. J. Hartog, of Owens College, and Dr. J. F. Tatham, Medical Officer of Health for the City. Some alarming statistics have been collected. It is shown that the deaths from respiratory diseases, which are normally about 60 per week, during a foggy week in December last reached 200. Observations were accordingly made at various points in the city, and the amount of sulphuric acid and carbon estimated. The quantity was obtained by ascertaining the amount carried down by the snow, by collecting deposits on the roofs of greenhouses and by examining the incrustation on leaves of outdoor plants. It was found that during three days of fog an amount equal to 6 cwt. of sulphuric acid was carried down by the snow in one part of the city, and further away from the centre, near Owens College, the amount was over 4 cwt., the "blacks" over 2 tons, and the hydrochloric acid about 2 cwt. One of the results of the inquiry has been to emphasise the demand for cheaper gas, so as to stimulate its use for heating purposes in lieu of coal, and an effort is being made to bring pressure to bear upon the Corporation to reduce the present cost.

NEW RAILWAY.—The line of railway from Preston to Blackpool, which was sanctioned by Parliament about six years ago, is at last to be commenced. The capital has been found by the Manchester, Sheffield, and Lincolnshire Railway Company, and the contract has been given to Mr. Thos. Riley, of Fleetwood. The new line will open up direct communication between the South Yorkshire and Cheshire districts and the Lancashire seacoast, the only means of access at present being through Manchester.

SHORTER HOURS IN THE ENGINEERING TRADE.—A demand is at present under consideration by the Iron Trades Employers' Association for the reduction of the working week from 54 to 53 hours. It is said that one important firm has conceded the point, but there are others who are not disposed to do so. In some cases it will mean an advance of about 2 per cent. on the cost of production.

THE CHANNEL TUNNEL.—A lecture was delivered by Professor Boyd Dawkins on the 13th inst. on this subject. After dealing with the general aspects of the question, the lecturer said that the borings showed that there was over the whole distance a grey impervious rock well suited to the purpose of a tunnel. The inclination of the rocks was very gentle, being 1 in 72 on the English side, and reaching 1 in 42 on the French side. The character of the rock was eminently suited for boring easily, and as during construction compressed air would be used the ventilation would be perfect.

THE SHIP CANAL.—An influentially signed requisition of citizens of Manchester asking the Mayor to call a meeting to consider the proposal of the City Council to advance to the Ship Canal Company the sum of money required to complete that work has been presented, and the meeting is fixed for the 23rd inst. The report of Admiral Richards, Acting Conservator of the Mersey, has been issued, and states that no improvement of value is to be noticed in the condition of the channels from the dredging at the bar. A report is appended of the progress of the Ship Canal works, and the report states that the works within the estuary are so far completed that no further legal or technical questions will be likely to arise.

THE LINEN AND JUTE TRADES.—There has been a better feeling this week, merchants having received larger orders from their retail customers. A strong feeling of dissatisfaction is, however, expressed by agents for manufacturers at the condition of business from their point of view. This feeling arises from the excessive home supply of goods, to which reference has previously been made in the course of our reports. Prices are of course cut down to a very low level under existing conditions, and they will probably decline further, as far as coarse grades of linens are concerned. Standard 10½oz. 40in. Hessians have been sold at the extremely low price of 1¾d., a figure which approximates to the then unprecedentedly low figures accepted in 1885, when Dundee Hessians were sold at 1½d., and Calcutta was competing with the Forfarshire manufacturers at their very doors, the burlaps of the Indian capital being sold in Dundee itself. The shipping business continues to be unsatisfactory. Another large failure in Montreal has had little effect here, as the feeling of extreme depression has passed away so far as the Dominion is concerned.

GLASGOW, 19th March, 1891.

THE PIG IRON TRADE.—The promoters of the Pig Iron Warrants Bill, who were thought to have been defeated by the Iron Trade Association, and to have been forced to abandon the Bill, seem indisposed to do so. They intend to persevere with the Bill, notwithstanding the storm of opposition it has raised. The opponents of the Bill say that, if it passed, there would be no longer an open market for iron, and that warrants would thereupon become unsaleable. The measure would, however, certainly operate in restraining undue speculation.

THE SCOTTISH RAILWAYS.—The North British Railway dividend of 1½ per cent. on the preferred ordinary and nothing upon the ordinary stock was neither more nor less than was anticipated, the forecasts of speculators having been in this instance exactly fulfilled. The full extent of the loss having been realised by anticipation, the stock began to recover from the lowest point almost immediately the dividend was declared. Still, there is not much inclination to force the price up again. In August, two months before it became apparent that a strike was probable, the combined prices of the split stocks was 154. On the making up of last account the combined stocks stood at 107½, representing a fall of 50 per cent. on the par value of the stock. Last half-year the North British Company paid a dividend at the rate of 3½ per cent. per annum on their ordinary deferred, and on the ordinary preferred at the rate of 3 per cent. The reduction of 5 per cent. out of the 6½ per cent. declared in the former half-year means a falling off in the amount available for dividend to the extent of about £208,000. The whole of this deficiency is not due to the strike. The accidents at Milngavie and at Winchburgh have together cost the company a large sum, and the aggregate amount of the items of loss, exclusive of the strike, is estimated at about £60,000, leaving about £150,000 which the company admit that they have lost through the strike. It cannot, perhaps, be ascertained at present whether the whole of the loss due to the strike has been charged. The loss of half a year's income to the ordinary shareholders of the 8¼ millions of ordinary stock of the North British Railway is, however, sufficiently serious.

CONFERENCE BETWEEN DIRECTORS AND RAILWAY EMPLOYÉES.—The North British Railway Company has issued a report detailing the concessions arranged at the conferences between the directors and the men which have been taking place during the past few days. The concessions are very important, and it is to be hoped will be generally and cordially accepted by the men. The system of payment by a fortnightly aggregate has been replaced by one of a weekly aggregate. The number of hours in this aggregate is seventy-two, involving, according to the circular of the company, an actual running time of ten hours per day The system of "booking off and on," which causes payment for a smaller number of hours than the number actually spent on duty, has been abolished, and the time of the men will in future be counted from the time they commence duty by order to the time they finish work. Intervals of at least nine hours' rest will be given so far as the necessities of the service permit. There are sundry minor concessions.

THE EDINBURGH RAILWAY SCHEMES.—The Caledonian Railway scheme for access to Edinburgh by means of a tunnel under Princes Street has been thrown out by Parliament. The Bill was opposed by the North British Railway in the interests of their own scheme, the Princes Street proprietors also appearing by counsel against it. There was an unusually full bar, almost all the leading railway counsel being employed in the case. The Edinburgh Town Council were not united in their attitude, and therefore their influence in the matter was rather discounted. On the 16th inst. a large and influential meeting was held in Edinburgh to protest against the carrying out of the scheme. The schemes, both of the Caledonian and of the North British Companies, are very unpopular in Edinburgh, and only urgent necessity would reconcile the people of Edinburgh to submit to either of the schemes. The Caledonian Bill has, however, been sacrificed to public clamour, while the North British Railway Bill has succeeded in passing. The Glasgow South Suburban Railway is a short line from Parkhead, in the extreme east of Glasgow, *viâ* Tollcross, Carmyle, Cambuslang, and Mount Florida, to Strathbungo. Parkhead is on the North British system, and Strathbungo is on the Glasgow and South-Western. The line will thus form an additional connection between the two railways.

SHIPBUILDING.—The Peninsular and Oriental steamers "Rome" and "Carthage" are about to be lengthened by Messrs. Caird & Co., Greenock. The vessels will be taken successively into Garvel Graving Dock, and there cut and lengthened. It is expected that the work will take about six months. There are at least two large contracts which Clyde shipbuilders seem reluctant to take at a fixed price in the present state of uncertainty of the prices of material and labour. Either the contracts will be given on the principle of "time and stuff," or they will be allowed to go elsewhere.

NEW GLUCOSE MANUFACTORY.—The manufacture of glucose, until a few years ago a product almost entirely imported from Germany, has within the past few years been developing in Greenock. A sugar refinery, which

Digitized by Google

has been closed for some time, is just now being converted into a glucose factory. The rapid development of the preserve trade in Scotland has directed the attention of capitalists to the manufacture of materials used in the making of preserves. The preserve trade in this district has been very prosperous for several years, and several firms, which were only in a small way of business five years ago, are now building very extensive factories to meet the needs of a rapidly expanding trade.

(From our own Correspondents.)

LIVERPOOL, 18th March, 1891.

The "City of New York."—This American liner has just made a remarkable passage to New York; and although she has not beaten the record of the fastest run across the Atlantic, she has made 500 knots or more per day for four days in the passage, her runs being 502, 485, 501, 500, 503, and 359 knots, no steamer ever having made such running before. The total distance of 2,886 knots—being nearly 100 knots further than is usually run at this time of the year—was run in 6 days 2 hours 10 minutes. She left Liverpool at 9 p.m. on the 7th inst., and arrived at Sandy Hook at 8 a.m. on the 14th inst.

The North Wales Passenger Service. — There is every probability of the passenger traffic between Liverpool and the watering places on the North Wales Coast being carried on this next season without any competition. Last year the Liverpool, Llandudno, and Welsh Coast Steamboat Company—the old company—competed with the owners of the "St. Tudno." The former company has gone into liquidation, and the "St. Tudno" has been sold, and in their place a new company has been formed principally of the directors of the two competing companies. The "Bonnie Princess," the "Prince Arthur," and the new boat which was being built for the owners of the "St. Tudno," have been acquired by the company, as well as the goodwill, fixtures, and other assets.

Dock Extension in Liverpool.—The proposed Mersey Docks and Harbour Board extension works consist of (1) the deepening of the Canada Basin; (2) the construction of a pier or jetty from the Canada Basin to Brocklebank Dock; (3) the lengthening and deepening of the Canada Lock; (4) the removal of the passage between the Canada and Huskisson Docks; (5) a new dock at the north-east corner of the Huskisson Dock; (6) the lengthening and deepening of the Huskisson Lock; (7) a new half-tide dock with three-lock entrance; (8) a new graving dock; (9) the deepening of the navigable waterway of the Mersey. Three years are given for the compulsory purchase of the land, and ten years for the completion of the works. The estimated cost of the works is £1,600,000.

SHEFFIELD, 18th March, 1891.

Iron and Steel. — Business is good in both these branches of trade, and all the mills and forges are working full time. The Rolling Mills Association, whose members mainly roll the particular sections used in Sheffield trades, are fully employed at the increased rate of charges decided upon by the Association last year. Their mills are also turning out a large amount of round, square, and other sections of a very mild quality. Sheffield also manages to retain the bulk of the orders from the Birmingham and Coventry firms for cycle steel. The annual report of Messrs. Charles Cammell & Co., Limited, is, on the whole, very satisfactory. It shows the profit for the year 1890 to have been £187,527 7s. 6d., and the directors recommend a dividend on the A shares of 5 per cent., and on the B and ordinary shares 12½ per cent. Messrs. Wm. Jessop & Sons, Limited, have issued their fifteenth annual report, and will pay a dividend of £6 13s. 4d. per cent. The directors complain that the increased business of the firm has been unprofitable on account of the high cost of labour and fuel. The heavy steel casting trade done by this firm has not been so profitable as was anticipated in the first instance.

Coal and Coke.—Steam coal is in active demand, and the amount forwarded to London by railway is fully maintained. The Humber ports are also exporting a large quantity. Prices remain from 10s. to 11s. at the pit's mouth. Household coal is in brisk demand at full rates. There is a demand for the best hard coke, but the market generally is quiet.

SWANSEA, 18th March, 1891.

Dock Extensions.—Sir George Elliot stated at the recent meeting of the Alexandra Docks and Railway Company, Newport, that the great work of their South Dock extension is drawing near to completion. The number of hands employed has been increased, and Mr. Smyth, the engineer in charge, quite anticipates that water will be let into the dock during the present year. The services of Mr. Charles Liddell, the eminent engineer, have been retained for consultative purposes.—The Milford Docks Company have completed their dry dock, 600ft. long, which, with the newest appliances, can be emptied in from three to four hours. The steady progress that the trade of Milford manifests, although encouraging, does not yet include the making of this port their terminus by Atlantic liners. Clearly, however, this is not for want of accommodation, for the s.s. "Maryland" (4,000 tons), recently blocked at Swansea, left this place with sealed orders, put into Milford, discharged her cargo of copper ore, took in coals, and left the following day for Philadelphia. It is interesting to note that, notwithstanding the sealed orders, a union delegate arrived at Milford by an early train and did his best to prevent the ship being coaled. The dock manager, however, had no difficulty in arranging for trimmers.

BARROW-IN-FURNESS, 18th March, 1891.

Hematite.—The hematite pig iron trade still remains very quiet, and orders are few either on home or foreign account. The trade consists chiefly of operations on warrant iron, which is selling at 49s. 9d. per ton, net cash, while makers are quoting 52s. to 54s. for parcels of mixed numbers of Bessemer iron, net f.o.b. The trade in forge qualities is inactive, but Bessemer iron is likely to be in improved request. The output is steady, forty furnaces being still in blast, and thirty-six standing idle. The stocks of warrant iron have been further reduced this week by 3,464 tons, and now amount to 196,212 tons.

Steel.—The only feature in the steel trade is the presence of new foreign orders in the steel rail market. Makers have been on short time for several weeks, and new orders are required to maintain the state of activity which has existed for a few years past. Prices are easier at £4 12s. 6d. for heavy sections, £6 for light sections, and £7 for colliery rails. In steel shipbuilding material there is a good prospect of new orders, and the mills are busy. A development of the Siemens-Martin steel trade in Barrow is being carried out, which will extend this branch of industry. Hitherto the West Coast has mainly confined its operations in steel to the Bessemer process, but in future the Siemens-Martin process will probably take pre-eminence. Tin-plate bars are quiet, as also are blooms, billets, and slabs.

Iron Ore.—There is a very quiet trade in iron ore, and prices are easy at 10s. 6d. to 11s. 6d. per ton for ordinary qualities. At many of the mines short time is being worked, while at others iron ore is being stocked.

Shipbuilding and Engineering.—On the 25th inst. the Naval Construction and Armaments Company will launch the third and last of the fleet of three fast ocean steamers which have been built to the order of the Canadian Pacific Railway Company for the Pacific trade. She will be named the "Empress of China." "The "Empress of India" is now making a successful tour round the world, and the "Empress of Japan" is expected to leave Barrow in a few days in order to make her trial trip. The second cruiser built at Barrow for the Admiralty, the "Melampus," is nearly ready to go to sea for her trial trip. Prospects of shipbuilding at Barrow are very good.

MIDDLESBROUGH, 18th March, 1891.

Pig Iron.—The pig iron market is very dull in consequence of rumours of financial disturbances in London. Decreased shipments also have increased the depressed feeling and darkened the hopes which naturally arise at this season of the year. Makers, however, will not commit themselves to prices which would be unremunerative, and hope to obtain better prices in the immediate future. Cleveland warrants may be had at 40s., but buyers will not give more than 39s. 10½d. Makers hold out for 40s. 6d. prompt delivery, and 41s. for April delivery. The average quotations may be taken as—No. 1, 43s. 6d.; No. 3, 40s. 6d.; No. 4 foundry, 40s.; No. 4 forge, 39s. 6d.; mottled and white, 39s. per ton for G.M.B. for delivery over the month. In hematite iron East Coast brands are 54s. per ton f.o.b. sellers, makers' iron, mixed numbers. The stock in Connal's stores on the 16th inst. stood at 126,156 tons, being an increase this month to the extent of 1,727 tons. The Cleveland ironmasters held a meeting on the 16th inst., and decided to ask the executive of the National Association of Blast Furnacemen to meet them for the purpose of arranging a substantial reduction in wages.

Shipments of Pig Iron.—The shipments of pig iron from the port of Middlesbrough for the week ending on the 14th inst. amounted to 14,580 tons, as compared with 12,266 tons over the corresponding period of last year. The shipments for the current month up to the 16th inst. amounted to 32,550 tons, as compared with 41,093 tons to similar date last month, and 24,404 tons to the 16th of March last year. Of the 32,550 tons, 20,275 went to Scotland, against 5,361 last year; 3,535 to other parts of England and Wales, against 1,995 last year; and 8,740 to foreign parts, against 17,048 last year. No doubt the severe weather has been adverse to the foreign trade, and milder weather will cause larger shipments for abroad.

Manufactured Iron and Steel.—The manufactured iron trade is quite as dull and the outlook quite as gloomy, and this remark applies to the steel trade as well. At the Darlington Iron and Steel Works the men have received a seven days' notice, to be followed by a twelve hours' notice, which indicates a shortness of work. On the other hand, Messrs. Bolckow, Vaughan, & Co., in addition to some smaller orders, have just received an order for 16,000 tons of steel rails for India. Iron ship plates are quoted at £5 12s. 6d.; angles, £5 10s.; common bars, from £5 12s. 6d. to £5 15s.; steel ship plates, £6 2s. 6d.; angles, £5 17s. 6d.; heavy steel rails, £4 12s. 6d. per ton, all less 2½ per cent. f.o.b. at works. The minor branches of the iron industry are fairly well off for orders, but the future is hardly so promising. The tube works, wire works, and pipe works are very well employed, but the general foundry works do not fare so well, one cast steel foundry having closed for a time. Shipbuilding is steady enough in the meantime, but the prospect is not very good. The general engineering and marine engineering trades are busy. Coal is steady, and coke for blast furnaces can be had slightly cheaper, from 14s. 6d. to 15s. per ton delivered at the furnaces.

SUNDERLAND, 18th March, 1891.

The Shipping and Coal Trade.—Although freights generally continue to be depressed there is a slight improvement of trade. Unfortunately the Silksworth dispute has not yet been settled, and the remaining collieries of Lord Londonderry have also been laid idle. Coal shipments are low, only 56,629 tons having been shipped during last week, although in the previous week 65,820 tons were sent coastwise and abroad. The remaining shipments—patent fuel, coke, cement, and general cargoes—were of an average amount. The imports included 39,801 sacks of wheat, timber, and iron ore.

Shipbuilding and Marine Engineering.—Outdoor operations have been much retarded by the severe weather, but the work in hand, including a quantity of heavy repairs, suffices to maintain continued general activity. The marine engines and boilers for two vessels recently contracted for by local shipbuilders are to be constructed on the River Wear. Mr. John Dickinson, Palmer's Hill Engine Works, has secured the order for the engines and boilers for the Londonderry Company's new steamer, and Messrs. George Clark, Limited, Southwick Engine Works, have also received a contract for a set of triple-expansion engines and two large boilers.

The Shipping Federation and the Seamen's Unions.—At a conference held here between the representatives of the National Seamen's Union, the North of England Seamen and Firemen's Society, and the local committee of the Shipping Federation, on the 13th inst., it was decided that the Federation ticket should be generally adopted. Previous to the conference large numbers of the members of the societies had accepted the shipowners' requirements, and the result of the conference was a foregone conclusion.

The Glass Trade.—Messrs. J. Hartley & Co.'s employés are still idle, declining to accept the terms offered by the firm. Strike pay has been distributed.

NEWCASTLE, 18th March, 1891

The Coal Trade.—Since last week no appreciable change has taken place in the condition of the local coal trade. The shipments of coal and coke at Tyne Dock for the week ending on the 14th inst. amounted to 105,291 tons, being an increase of 2,599 tons as compared with the shipments in the corresponding week last year.

Shipbuilding.—In the shipbuilding trade new orders are still scarce, and the fact that shipbuilders have considerably reduced their quotations for tonnage does not seem to induce speculation on the part of owners. The unremunerative state of the freight market, coupled with the recent labour difficulties, are sufficient to account for the unwillingness of shipowners to make further additions to their fleets. There is also the circumstance that a large amount of tonnage is now laid up, and, under these conditions, it is useless to expect any appreciable increase of work in the shipbuilding trade. Special requirements will, of course, have to be provided for, and occasional orders will be forthcoming to fill up vacancies on the stocks of some establishments. On the whole, the outlook for the shipbuilding industry is far from encouraging, and when the old orders now in hand have been completed it is to be feared that a very serious slackness will be felt. Messrs. Armstrong, Mitchell, & Co. are about to launch from their Low Walker Yard a small twin-screw steamer for a special service. The firm have just put down the keel for a large vessel, and they have two others, also of large size, in the framing and plating stages. A few other firms have recently put down keels, but in several instances where launches have taken place lately the berths still remain vacant. A small steel steamer is being built for local owners at the Mushroom Slipway, near Newcastle. For some years past only repairing work and the building of small wooden vessels have been carried on at this establishment.

Engineering.—The leading engineering establishments continue to be well employed, and there is now a prospect that the overtime question, which, for some time past, has caused uneasiness, will be amicably settled. At Messrs. John Abbot & Co.'s establishment business is fairly active, colonial contracts for hydraulic machinery forming a large part of the work in hand. The works of Messrs. John Spencer & Sons, at Newburn and Newcastle, are kept briskly going, though orders for ship forgings are not so numerous as they were a few months ago. The erection of the new ordnance works at Jarrow is being pushed forward with all possible despatch, and it is probable that within a couple of months the buildings will be ready for the reception of machinery. Mr. W. F. Snowdon, the agent for the new American wood split pulleys, recently introduced by Messrs. Braithwaite & Son, Kendal, is doing a large business in these specialties, among recent orders being an important one from a Sunderland shipbuilding firm.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 20TH MARCH, 1891.

THE LONDON WATER SUPPLY.

AT the beginning of the present session we had occasion to review the complex nature of the problem of the future water supply of this great metropolis. Although during the interval considerable progress has been made by the introduction of the Bills which are now under discussion in Parliament, and by the systematising of our information by the County Council and other bodies, the problem is still very complex. As we have already pointed out, the monopolies of the metropolitan water companies are of such a character that many debatable points must necessarily arise in dealing with this topic, and in London there are so many conflicting interests that the solution of the question is not likely to be accomplished without considerable difficulty. Although the problem in London is much more formidable than any similar conversion in our provincial towns, it must not be forgotten that it is one of precisely similar character to that which has been successfully dealt with in several places. Moreover, when the present problem is considered in relation to the wealth and administrative powers of the metropolis, the difficulties are seen to be more than counterbalanced by the special facilities which exist in London for such a step as the one contemplated.

At the present time Parliament is considering no less than six Bills which have reference to this question. The London Water Commission Bill, the Southwark and Vauxhall Water Bill, and the Croydon Water Supply Bill are all of a private nature, and are being petitioned against by the London County Council, while, on the other hand, the Metropolis Water Supply Bill, the London Water (Meter) Bill, and the Metropolitan Water Companies (Charges) Bill are of a public character, and are more likely to meet with success in their original or modified forms. On the motion for the second reading of the London Water Commission Bill, Mr. Baumann said that after twenty-five years of discussions, advocacy before Select Committees of the House, and Royal Commissions, Londoners at last seemed to be within reasonable distance of obtaining the control of their own water supply. We sincerely hope that, notwithstanding the apparent chaos, his wish may be realised. Those who are interested in the question seem to have agreed that the time is now ripe for an amalgamation of the various water companies in London into one corporate body, and the London Water Commission Bill, promoted by the Corporation, and the Metropolis Water Supply Bill, promoted on behalf of the vestries, both formulate this end as the one to be desired. The former of these two Bills only proposes the establishment of a Commission to consider and submit to Parliament Bills dealing with the subject. It will, however, if passed, practically give the power of deciding the question to the City, as the proposed constitution of the Commission is such as to prevent the County Council having a working majority thereon. Under such a Commission it is more than probable that the London water supply would be entrusted to an entirely new body of the nature of a Trust, which would be entirely independent of the existing County Council. The County Council, on the other hand, consider that they should be the body entrusted with these new duties, and hope by opposing the City Bill to obtain their wishes in this direction. The Council further urge that the Commission would be ill adapted to settle the question, not only owing to its hybrid nature, but also to its want of any definite income with which to carry out its work against the probable Parliamentary opposition of the water companies. We believe that the objections urged against it by the County Council are of sufficient weight to lead to the probable final abandonment of this Bill. The Parliamentary Committee of the County Council are likewise strongly opposed to the Metropolis Water Supply Bill of the vestries, partly on the same grounds as have been advanced in opposition to the City Bill, and partly because the Bill assumes that the existing water undertakings must be immediately purchased by arbitration. They point out that such a procedure might cost the metropolis a sum far exceeding the real value of the existing undertakings, and suggest that if powers were given for the establishment of a new supply the price to be paid for the old would at once sink to its normal value. The Committee have, therefore, come to the conclusion that the interests of the citizens will best be served by the opposition of the Council to both these Bills. In the event, however, of a Select Committee being appointed, it is prepared to undertake the question of the water supply of London, subject to the following conditions:—That powers should be conferred on the Council for the introduction into Parliament of Bills dealing with the water question, including the establishment of a new supply, and the improvement of the existing supplies, if further investigation should prove such a course to be desirable, and the Chairman of the Council is to be requested to introduce a public Bill with this object. We thus see that the complexity of the problem is to be still further increased by the County Council's Bill with the above object, and, although rather late in the day, they are to be congratulated on at last taking a forward step in this direction. We cannot help thinking that, if the London County Council had been alive to the urgency of the solution of this problem, they would have formulated their views many months ago, and thus have saved the vestries and the Corporation their labour in attempting to settle the question. The London County Council, if only they can be stimulated to work, are well adapted to undertake this new function, and the feeling which exists as to their unsuitability is mainly caused from their lethargy and tardy action in this and other matters. On previous occasions we have had occasion to criticise their apparent want of action in the reforms needed in the gas lighting of London, and we believe that if the evils of the increasing water rate, due to the quinquennial valuation, had not arisen, their sudden activity at the last moment with regard to the water question might not have taken place. Although delays are proverbially dangerous, the Council's action is better late than never, and we trust that their slow movement is also sure. It must not, however, be forgotten that the County Council were not able, before the Act of last year was passed, to inquire into the question of fresh sources of supply, and that their engineer, Mr. Binnie, has already presented a long report on

Digitized by Google

possible new sources of water for London. In this report it is pointed out that much additional information is wanted in order to form an opinion as to the present supply and its possible extension from the River Thames, the River Lea, and the chalk. The report further states that in the event of such inquiries proving that the present sources are inadequate, the Welsh scheme from the Upper Severn, the Welsh scheme from the Upper Wye, the Cumberland Lake scheme, or the Devonshire scheme, the latter being a fresh suggestion of Mr. Binnie, are amongst the proposals for a new source of supply. It cannot be too strongly urged that the continual sinking of artesian wells in the London district is likely to cause very considerable disadvantages to the suburban districts. Moreover, according to any of the proposed schemes, the water will be brought into the metropolis at an altitude of some 240ft. above the level of the Thames, and thus reduce the enormous annual charges of pumping which attend the existing supply. The value of the work begun cannot be over-estimated, and we trust that in a short time we shall find the question, of which we have endeavoured to give a short outline, narrowed down to a definite issue. We hope that out of the confusion which at present exists a line of policy will be evolved which will bring the various conflicting elements into harmony.

THE NEW TORPEDO GUNBOATS.

In a recent article (see *Industries*, Vol. X., page 169) we drew attention to the shortcomings of the "Sharpshooter" type of first-class torpedo gunboats in the matter of speed and power, as revealed by their numerous trials. Since then the Navy Estimates for the ensuing financial year have been issued, and the policy of the Admiralty with regard to further increasing the *matériel* of the Navy by adding to the various types authorised to be constructed under the Naval Defence Act, has been made known. It appears that the first-class torpedo gunboats "Circe" and "Hebe," now on the stocks at Sheerness, and the "Antelope," building at Devonport, the construction of which has been delayed for some time pending alterations, is to be pushed forward, and that two sister vessels, to be named the "Alarm" and "Leda," will be laid down shortly at the former establishment. The engines of the "Hebe" are to be constructed in the dockyard, while contracts for the machinery of the "Circe," and also of the "Alarm" and "Leda," have been placed with Messrs. John Penn & Sons, of Greenwich.

From the close of the last financial year ten vessels of this class have passed through their machinery trials—viz., the "Sharpshooter," "Spanker," "Speedwell," "Seagull," "Salamander," "Sheldrake," "Skipjack," "Gossamer," and the colonial gunboats "Karrakatta" and "Boomerang." Not one of these vessels realised or even approached the 21-knot speed and 4,500 horse-power which were the original estimated figures. The nearest approach, however, to the official figure for horse-power was obtained with the "Karrakatta," which, with her sister the "Boomerang," was built at the Elswick shipyard of Sir William Armstrong, Mitchell, & Co., and engined by Messrs. Belliss & Co., Birmingham. On a three hours' forced draught trial, which took place off Tynemouth in July last, the engines of the "Karrakatta" developed a mean indicated horse-power of 3,840, the air pressure being 1·76in., and the revolutions per minute 270·35. Half-hourly records were taken during the trial, and the greatest horse-power was registered during the sixth half-hour, the total for the port and starboard engines being 3,896·5, a result which may be considered highly satisfactory when taken in comparison with other vessels of her class. The "Boomerang" was subjected to a three hours' trial during the same month, when, with a slightly less pressure of steam in the boilers, the following results were recorded:—Mean horse-power, 3,508; revolutions per minute, 262·3; with an average air pressure in the boiler-room of 2in. of water. With reference to the three hours trial of the "Boomerang," the Admiralty fixed 3,500 as the i.h.p. for this trial, and we believe the contractors were officially ordered not to attempt to exceed this power. The mean horse-power obtained—viz., 3,508—was the nearest approach to the official regulation.

Considering their lightness of construction, too much was expected from this type of vessel in the first instance, but after a lengthened experience, gained from the numerous speed and power trials, the Admiralty have learnt how far it is prudent to force the engines, and have finally concluded that 3,500 horse-power is all that can be safely expected. As a consequence, the estimated power for the machinery of the new vessels has been reduced to this figure, and the stipulated weight on which this power is to be developed is 204 tons, or 17 horse-power per ton. These modified conditions ought to be, and no doubt will be fulfilled without difficulty by the engineers who contract for the machinery, especially in view of what has already been accomplished in the "Karrakatta." The weight of the machinery in this vessel, as in the others of her class engined by Messrs. Belliss & Co., is 160 tons. Taking this figure in relation to the recorded horse-power of 3,840 developed in the "Karrakatta," the horse-power per ton weight of machinery reaches as high as 24. Hitherto the boilers have been a great source of trouble on account of the serious leakage of the tubes which develops after a short period of steaming under forced draught. There is no doubt that the special difficulties experienced with the "Sharpshooter" were largely due to the fact of her being the first of a class, and that a number of trials had to be made before the local vibrations in the hull had been met by special stiffening, which was subsequently introduced into all the other boats of this class. It may be understood, however, from remarks recently made by Lord George Hamilton in the House of Commons, that important improvements are to be embodied in the boilers of the new vessels with a view to realising the modified conditions on trial without fear of disappointment; and it is certain that anything which may be adopted to minimise the difficulties and risks attendant on working under forced draught will be greeted with satisfaction. In the opinion of some experts the wet bottom type of locomotive boiler as fitted in this class is not so well adapted for a forced draught performance as the usual locomotive boiler employed in some of the larger torpedo boats, unless special means are provided for circulating the water. The practice, too, of submitting boilers of this type to the severe ordeal of working at their maximum power almost "straight off the reel," without having previously been used for a considerable time under easy conditions of service, has been objected to by some authorities on the grounds that both boilers and tubes require time to settle into a good working condition. There is scarcely any doubt but that in the early vessels the boilers were worked beyond what they should have been in endeavouring to attain the official estimated results, and it is hardly possible that anything approaching a 19·5 knot speed could be again accomplished without much "puffing and groaning." It is to be hoped, however, that the changes made in the machinery and boilers of the new vessels will enable them to steam continuously at 19 knots, and, if this is realised, it will be much better than being compelled to recognise a paper speed of 21 knots, upon which a reduction of from 12 to 15 per cent. has to be made before the true speed is approached.

THE AMERICAN POSTAL SUBSIDY AND SHIPBUILDING.

The Postal Subsidy Bill, which has been passed by the American Legislature, may be described as a Bill designed to encourage American shipbuilding, for, although the proposal to give direct bounties to the shipbuilders was rejected, the Bill which was carried will have practically the same effect, as it stipulates that the subsidies paid on the miles run are only to be paid on vessels of American build. The modified proposal was accepted by the shipbuilders and shippers, who hoped to benefit by protective measures, not very willingly, and only when they saw that by insisting on more they might lose all. The steamers to be built under the subsidy are divided into four classes, the grants ranging from 66c. per mile for the lowest to $4 per mile for the highest. The latter are intended for the Atlantic trade, and are required to be of 8,000 tons burden, and to have a speed of 20 knots in ordinary weather—that is to say, to be about equal to the best steamers at present on the route. But it is reported that an enterprising syndicate proposes to go beyond this, and build steamers of 12,000 tons and capable of steaming 24 knots per hour, and thus be able to run from New York to Milford Haven at a rate which will allow their passengers to be landed in London within five days from New York. In a recent issue (see *Industries* of the 6th inst.) we gave a sketch of the development of steamer speed on the Atlantic, and stated that, while ordinary mortals were willing to be content with present accommodation, and with a speed which carried them from Liverpool to New York in a little over six days, in the new Cunard liners an attempt was to be made to excel everything that had yet been done in both of these respects. We believe that 21 knots is the speed aimed at in these steamers, but already, before their keels have been laid, we hear of a proposal to attempt 24 knots in the new American steamers. We do not by any means say that the thing is impossible, but we are afraid that in attempting to attain it our American friends may find that their subsidy is more than swallowed up, for the leap from 20 to 24 knots involves a very large proportionate increase of power and of expenditure, and American shipbuilders, who have not yet produced any steamer of a greater speed than 17 knots, should consider well what they are doing before involving their clients in what may prove to them disastrous expenditure. It is stated that it is expected that, within two years, the first four ships will be in commission, and thus be able to share in the great increase of traffic which is expected to take place in connection with the International Exhibition.

The second class of steamers provided for in the Bill are to be of smaller size and speed, being 5,000 tons and 18 knots speed, and are intended for the Pacific trade, and it is understood that the Pacific Mail Steamship Company have already ordered three new steamers, each over 5,000 tons, while the Morgan Steamship Company is building two steamers of about the same size for the South American trade. Smaller subsidies are arranged for smaller steamers for coasting trade, so that every department of the shipping industry in America will be affected. We believe that a movement has been started in the Southern States for establishing direct steam communication with Europe, which promises to lead to practical results. Conventions have recently been held at various Southern ports for the purpose of inaugurating companies, and they have received promises of a considerable amount of support, and if they are fairly launched they will doubtless claim a share of the subsidies. It is still too early even to speculate on the results of these measures on British shipping and shipbuilding, but there can be little doubt that they will have a great effect on the contest of size and speed, which has for some years been going on, and may lead to developments far beyond our present expectations.

THE INFLAMMABLE LIQUIDS BILL.

The Bill which has been introduced into the House of Commons by the Home Secretary, for the purpose of amending and consolidating the law relative to the keeping, selling, and transit of inflammable liquids, is of considerable importance, and will, no doubt, be the subject of a large amount of discussion both in and out of Parliament. Several attempts have been made to legislate on this subject, but unsuccssfully, and the present measure is an elaborate attempt to meet the requirements of all the cases likely to arise.

By the present Acts, petroleum which requires a temperature of not less than 73° Fahr., when tested in Sir F. Abel's closed apparatus, in order to give off an inflammable vapour, is not reckoned as petroleum for the purposes of the Act. The Home Secretary's Bill proposes that there should be no exemption until we reach a flashing point of 150 degrees. The old limit, however, is recognised, and all oils with a flashing point of 73 degrees and under are classed as "mineral spirit," and those above it as "mineral oil," and regulations have been made for the articles to be found in each category. What has hitherto been defined as "petroleum" will, under the proposed measure be known as "mineral spirit," and the regulations regarding it are somewhat drastic. It is only to be kept in premises specially licensed for the purpose, except in quantities not exceeding three gallons. What is defined as "mineral oil" is henceforth not to be kept, except in premises specially licensed or registered under the Act, unless the total quantity does not exceed sixty gallons. No doubt these restrictions would render explosions from inferior kinds of oil far less common, and thus no doubt would add to the public safety; but the question which will require very careful consideration is whether the limitations are not too stringent. The country shopkeepers are up in arms against the measure, and have sent many circulars and petitions to the Home Secretary against the Bill. The Bill has, moreover, raised the opposition of the Scotch mineral oil manufacturers and of the merchants who deal in the article, and, while admitting that certain restrictions and regulations may be necessary, they look upon the present measure as one which will hamper their trade and prevent the free distribution of their products in the cities, villages, and country houses of the kingdom. They point out that there has been no serious accident from the use of their oil, and that the explosions and fires which have occured in private houses have been caused not by paraffin, but by petroleum, or by the use of lamps which were unsuited for either. A clause has been inserted in the Bill which prohibits the sale of dangerous lamps, but it is doubtful whether this is a wise provision, or can be of any practical use. A lamp

Digitized by Google

which is safe when sold may, by careless use, be soon rendered unsafe. Moreover, if people are to be guarded in all their actions by Acts of Parliament, what will be the result in every department of life?

In the official report, by Sir F. Abel and Mr. Redwood, there is sufficient evidence that in many cases the lamps used are neither properly made or designed, and that the regulations regarding storage and distribution require some modification, but we are afraid that some of the provisions of the measure would have far-reaching effects little dreamt of at present.

THE LATE SIR JOSEPH BAZALGETTE.

The late Sir Joseph Bazalgette, whose death occurred on the 15th inst., was born in the year 1819, and entered the engineering profession as a pupil of Sir John MacNeil in 1840. In 1845, during the railway mania, he was busily employed on his own account in designing schemes for the construction of railways and ship canals in various parts of the United Kingdom. In 1848 he was appointed an assistant engineer of the Metropolitan Commission of Sewers, and four years later obtained the appointment of chief engineer. In the year 1856 he became engineer to the Metropolitan Board of Works, when it was first constituted, and was called upon to devise and carry out a scheme of main drainage for the metropolis. Sir Joseph Bazalgette's scheme was executed between the years 1858 and 1865, and consists of three parallel sewers, a high level, a middle, and a low level sewer, all of which unite at Abbey Mills, not far from the Stratford Station on the Great Eastern Railway, and are thence carried down to the outfall at Barking, which is some distance below Woolwich. The high level sewer runs along the southern slopes of the Hampstead and Highgate hills; the middle level along Oxford Street, with a branch from Piccadilly; while the low level commences at Chiswick, and, striking the river alongside the railway bridge at Battersea, is carried under the Embankment and up Queen Victoria Street through the heart of the City. We may get an idea of the magnitude of this system, which already, however, has been proved inadequate to its task, from the fact that the average flow of sewage is estimated at 180,000,000 gallons per diem in dry weather. The execution of this scheme has greatly improved the sanitary condition of London, which was previously very unsatisfactory, and has added many years to the average duration of life in the metropolis. Sir Joseph Bazalgette's second important scheme was the construction of the Thames Embankment, which was carried out between the years 1863 and 1874. Before the embankment was made, as many of our readers will remember, there was a long expanse of mud along the banks of the river at low tide, which gave forth an offensive smell, and was very detrimental to health. In those days the contents of the sewers were discharged into the Thames over this mud, and this state of affairs continued until the main drainage system was carried into effect. As chief engineer of the Board of Works, Sir Joseph also had the control of all the bridges over the Thames as far as Hammersmith, with the exception of those in the City, and was responsible for the new Battersea Bridge. He also prepared designs for the new high-level bridge at the Tower, but the City claimed the right to carry out the undertaking at its own expense. On any question connected with railway, gas, or water Bills, Sir Joseph Bazalgette's opinion was of great weight when these Bills were referred to Parliamentary Committees. When the powers of the Board of Works came to an end, about two years ago, Sir Joseph Bazalgette retired, but since that date he has given evidence on several occasions on behalf of the London County Council.

THE SKILLED LABOUR MARKET.

The reports sent in to the Board of Trade by twenty-one trade unions, with a total membership of 239,909, show that of this number 6,231 were unemployed during February, as compared with 8,063 in January. The returns show that the proportion of the unemployed was 2·6 per cent. in February, as compared with 3·37 per cent. in the previous month, whilst the proportion of unemployed in February of last year was 1·4 per cent. The number of strikes was 116, or an increase of 43 on those of the previous month. Of the total number of strikes 29 were connected with coal mining, of which 14 were caused by the strike at the Silksworth Collieries, 29 occurred in the cotton trade, and there were 16 dock strikes. The condition of the skilled industries shows on the whole a distinct improvement on that of the previous two months. This improvement has been caused by the stoppage of the Scottish railway strike, which prevented the supplies of raw material from being forwarded, and by the favourable weather of February, which allowed building and other outdoor trades to resume their activity.

Letters to the Editor.

THE LONDON SMOKE AND FOG PLAGUE.

To the Editor of "Industries."

Sir,—I read with pleasure Mr. Thwaite's admirable reply in your issue of the 13th inst., and would like permission to add a few words.

It is quite true that the present form of fire-places is one which can only be radically changed by a sacrifice of prejudice, but I fail to see that there is any great necessity for altering the open grate system.

For some years I have had in use a Verity's gas stove, and a more effective fire for the purpose I have not seen, but this was attained at the cost of a considerable consumption of gas, making it more expensive than a coal fire by possibly 100 per cent. On one occasion, when it was constantly burning both day and night for six weeks, the saving of trouble in the room in which it was placed must have been very considerable, and with gas at half the price which we pay at present, it would have been a formidable competitor to the ordinary coal grate, and there is no reason to suppose this somewhat wasteful fire cannot be improved when attention is called to it.

The use of gas for cooking purposes has only to be tried in conjunction with cleanly practices to be keenly appreciated. It enables a household to undertake a much greater variety of dainties for the table, and punctuality is attained with much less anxiety to the cook. The labour and discomfort of cooking is enormously reduced.

I have recently been trying a Leeds stove, burned in competition with one of the so-called "condensing" stoves, and the effect upon the room of the former (which has no flue) is much smaller than might have been anticipated. The asbestos head or roof over the flame does not become blackened, although the burners are not atmospheric, but of the ordinary fish-tail pattern. A gasfitter recently expressed his opinion that this was because the burners were very small, and the combustion of gas was more perfect in consequence. I shall be glad to know if this is the case, as if so a solution to one of the difficulties of heating by gas is suggested.

Mr. Thwaite was good enough to refer to my proposal, but condemns the absurdity of perpetuating the wasteful carriage of coal. He is of course perfectly right, but in supporting reforms I am desirous of securing the proverbial "half loaf" when the whole one proves to be unattainable.

The treatment of this subject in our Houses of Legislature is not encouraging, but it is no new experience to see radical propositions treated with ridicule at the onset.

The remark in my first letter as to the production of residuals in the provinces is only partially answered by Mr. Thwaite, as the scheme would, I presume, involve the production of a largely increased quantity. It would be interesting to know how the market would be effected. I have some idea that this knowledge could be obtained if some correspondent would state what is the exported quantity of nitrate of ammonia, and the imported quantity of nitrates, as well as the possible requirements for agricultural and other purposes in this country.

As the project is supposed to deal with only $\frac{1}{7}$th of the fuel consumed in the metropolis, now used in the solid form, as compared with $\frac{1}{2}$th as dealt with at present by gas companies, it only provides for an increase of 40 per cent., an estimate I think very much too low, even assuming that gas firing is not appreciated for small steam boilers.

Yours, &c.,
James Armer, Assoc. M. Inst. C. E.

10 and 11, Queen Street Place, London, E.C.,
16th March, 1891.

THE INSTITUTE OF CHEMISTRY.

To the Editor of "Industries."

Sir,—The perusal of the articles appearing in your paper last month, particularly the opening paragraphs of the first one, reduced me, as a member of the Institute of Chemistry, to such a state of despondency that I was on the point of writing to our Registrar, saying: "*Peccavi*, remove my name instantly from the register, lest haply I be ejected for breaking § 15 par. 5 of our charter: 'Engaging in any occupation . . . . inconsistent with remaining a member of the Institute.'" Sir, I must confess I do not follow the "profession of analytical and consulting chemistry," nor dare I aspire to the name of *locum tenens* even to a professor's laboratory boy. I am a mere works chemist. In fear and trembling, therefore, I followed (though not for the first time) your advice and read the charter, when—joy! In § 5 I found that "chemists in technical industries" were specifically recognised, and so there has been one suicide the less.

Two things are evident from your articles: 1st, that the writer is himself an analytical and consulting chemist—*i.e.*, a public (more or less) analyst; and 2nd, that the time he spent at college was disgracefully misspent, except in so far as his "slumbering in lecture rooms" has helped him to his (probably) present proud position of a member of the Institute. Now, Sir, while I can sympathise with the desire of the analysts to increase the advantages (and incidentally the fees) of their pupils, and while I am behind no one in recognising their eminence in the profession of chemistry, I am fain to confess that, were I looking out for an assistant in my laboratory, I should prefer a professorially trained one, on the ground that eminence in a profession or art by no means postulates the ability to teach, and that of the latter it is easier to judge in the case of a professor, because of the large number of pupils turned out.

So far as I can make out, you desire to make chemistry a close profession (to which I by no means object) *so far only* as regards public analysts, thus leaving to works managers or directors no means of judging as to the competence of the men they desire to engage as chemists: a state of things that would lead to what cynics say already exists in the law—viz., that the lawyers in Parliament so draft the new Bills as to cause increased litigation, by reason of the rule-of-thumb methods into which manufacturers would gradually recede, owing to the lack of efficient technical advice.

I therefore object to the exclusion of all but analysts from the governing body of our one qualifying society.

Yours, &c.,
A Technological Associate.

London, 14th March, 1891.

THE INSTITUTION OF NAVAL ARCHITECTS.

The annual meeting of this Institution was opened on the 18th inst., at the rooms of the Society of Arts, John Street, Adelphi, London.

In moving the adoption of the report, which showed that the success of the Institution had been maintained, the President, Lord Ravensworth, referred to the great loss suffered by the deaths of Mr. Bernard Waymouth and Mr. William John. The council have determined to offer a gold medal for the best paper of the year, provided that it is not written by a member of the council. The council have also endeavoured to assist in the preliminary arrangements for this year's Royal Naval Exhibition in London, and, probably, a second session of the Institution will be held in connection with it. After referring to the papers to be read at this meeting, which he characterised as being of exceptional value, Lord Ravensworth dealt with the shipping industry of this country and its relations to the navy. About the middle of the summer of last year orders were very scarce, and ships were being built at a very low price. This attracted trade, so that the latter part of the year was marked by increased activity. In this way the total was brought up to 1,279,000 tons of shipping in the course of the year, being a decrease of 54,000 tons from the previous year. The prospects for the present year are very favourable, no less than a million tons being now in hand, so that there will be plenty of work for six months at least. The trade has been heavily handicapped by adverse conditions, such as high wages. At the present time there are more ships than there is trade for, and, owing to the high price of fuel, only ships of the newest and most economic type can be made to pay. Just in proportion to the increase of our trade so does Government obligation to provide protection for our mercantile service increase, and he felt bound to say that the activity in the royal dockyards showed that this obligation was met.

The first paper read was by Lord Brassey, on the "Future Policy of Warship Building." The author said that at the present time the reinforcement of the fleet is being pushed on with vigour, but the future programme must shortly be considered. The danger of laying down ships in batches before a single specimen has been tried at sea may be partly averted by their discussions. In considering the programme of future construction, it is essential to consider the two-fold duty of the navy—first, defence against invasion; second, protection of commerce. For the latter purpose the navy must guard the English and Irish Channels and their approaches and all the sea between Ireland and the Peninsula. As the range becomes wider protection must be given, in the open ocean by patrol, in narrower seas by convoy. In considering the programme of the future, not only naval requirements, but also political and financial considerations, must be regarded. It has been announced that the British navy is to be kept equal to the combined strength of any two other Powers, but for cruisers the measure should rather be the tonnage to be protected. The author gave a classification of the relative strength of England, France, and Russia. The following table shows the numbers of ships and their tonnage:—

	England.		France.		Russia.	
	No.	Tonnage.	No.	Tonnage.	No.	Tonnage.
First-class battle-ships	32	354,950	14	151,682	16	57,617
Second-class battle-ships	13	89,000	13	98,101	4	21,172
Look-out ships	19	36,390	6	7,740	—	—
Torpedo gun vessels	19	13,150	15	6,501	—	—
Coast defence ships	12	47,720	23	83,727	24	58,374
Armoured cruisers	18	137,050	12	63,446	8	62,223
Protected cruisers, 1st class	11	85,550	6	29,779	1	5,000
Protected cruisers, 2nd and 3rd class	46	157,511	8	17,208	2	5,900

Passing to the consideration of types, a British fleet must go anywhere and do anything. The first-class battle-ships must not be intolerable to the crews; they must be fully sea-keeping and sea-worthy. For this ample freeboard and high bow are essential. As to speed, 17 to 18 knots on the measured mile will be

Digitized by Google

sufficient, and coal endurance is hardly less important than speed. The armaments in future will not include the heavy guns, with their limited endurance and all their other disabilities, but will be restricted to 29-ton guns, with a penetration of 21in. at 1,000 yards. Battles will probably commence with attempts to ram, and, as the vessels approach, endeavours will be made to keep down the hostile fire by an incessant hail of bullets. Both major and minor armaments should give the greatest command of fire in the end-on position. Next, with regard to the armour, the introduction of projectiles charged with high explosives renders it indispensable to return to the system of protecting the upper works of ships with armour of limited thickness but of extreme hardness, capable of exploding the shells outboard. This armour is of great value against quick-firing guns.

The several elements which collectively constitute the fighting efficiency of a battle-ship having been dealt with, the limit of dimensions was considered. With every increase of displacement the naval architect can give more effective armament, stouter armour, a higher and more enduring speed, and a more ample coal supply. On the other hand, if dimensions can be kept within a margin of, say, 10,500 tons, as against 14,000, the same tonnage will give eight ships against six. A further argument against vessels of deep draught is their inability to enter any but deep harbours or to come inshore.

In look-out ships speed is essential, armament subordinate. There should be two of these vessels for each first-class battle-ship. As auxiliaries torpedo gun vessels are not less indispensable than look-out ships. They should have high speed and be armed with quick-firing guns. The flotilla for coast defence should include rams, monitors, and armed torpedo vessels of the "Polyphemus" type, improved. For coast and harbour defence a torpedo flotilla has been proved to be in a high degree effective. Experience has shown that the smaller torpedo boats are unseaworthy. It will probably be well to have torpedo boats of two classes. The first class, of not less than 150 tons, should be able to cruise with the fleet within a certain distance from the coast. The second-class boats, for harbour defence, may be of small size and cheap construction.

In cruisers superiority of speed and coal endurance are the primary qualities; weight of armament is subordinate. In the armament of the cruiser the heavy gun of the battle-ship should have no place. An unarmoured cruiser can never engage an ironclad on even terms. The weight absorbed in the 15-ton guns and their mountings of the "Mersey" class might possibly have been better applied in giving more protection to lighter guns. The necessity of a large reinforcement to the Navy of first-class cruisers, of the "Blake" and "Blenheim" and "Edgar" types, is strongly urged, and the necessity for the smaller class is obvious.

All suitable mercantile ships should be enrolled as auxiliary cruisers, and ships in course of construction for the merchant service should be carefully watched by the Government. With regard to expenditure, the amount to be expended during 1891 in France is £2,400,000. In England during 1890–91 the amount is £6,777,666, and for the next financial year £6,351,360. The author regretted to appear as an advocate of heavy expenditure, but it must be undergone if the defence is to bear any proportion to the increase in our mercantile service. Property exceeding £150,000,000 is always afloat under the British flag, and it must be suitably protected or attack and humiliation are invited.

The discussion on the paper was opened by a communication from Admiral Scott, who pointed out the necessity of high freeboard for accurate fire, as proved by the "Rodney." The large amount of water displaced by certain vessels, such as the "Polyphemus," when steaming, tends to render torpedoes nugatory by diverting their travel. Rams are likely to prove an important part of the vessel, though they cannot be used on the broadside of a vessel steaming rapidly, as they would be too much twisted. Simplicity of detail is of the greatest importance. He differed from Lord Brassey, in not wishing for more slow coast-defence ships, and, further, he adhered to vessels of the 14,000-ton class. The coal endurance has been much overrated in previous calculations, as it was mostly derived from the consumption in smooth-water trials, and no allowance had been made for the fuel used for auxiliary engines, search lights, or for the loss of steam in broken pipes, or other incidentals.

Admiral Colomb generally agreed with Lord Brassey's paper. A point, however, not touched on in the paper, is that there is always a sequence in naval warfare—ports cannot be protected at the same time that other ports are attacked. The history of the subject must be largely drawn on in these considerations, as he entirely disbelieved that steam alters the condition of naval warfare. At the beginning there was no classification of ships, except in the matter of size. Experience showed that medium-sized vessels were the best, and this tends to prove the author's point. Cruisers, in the same way, were restricted to 38-gun frigates and a very large number of small vessels to protect commerce. The "Blake" and "Blenheim" type, as equivalents of the 50-gun ships, will therefore tend to disappear. The necessity for two look-out ships to each line of battle-ship is supported by high authority, but does not appear to be backed up by any sound reasons or by precedent. Blockades, the speaker thought, would be an increasingly important factor in war. History, as exemplified in the American and in the Crimean wars, showed this, and also that the difficulty of breaking through has increased, and will increase.

Admiral Hopkins, the Comptroller of the Navy, thought that the paper had been read just at the proper time, when things were ripe for discussion. He proceeded to state the views of the Admiralty, and what they were doing. It is unfortunately true that the coal endurance is less than was calculated. In the new ships provision is made to carry 1,100 tons in place of the 1,000 tons called for by the author. He generally agreed that smaller guns are required. The large guns had failed in details from the first, so that people lost confidence in them. Rams, he thought, would be the chief weapons in the future, and the guns will take a very subordinate position. He did not believe in the "Monitor" type. The navy, in part, does want masts and sails, but it is difficult to apply them to double-screw vessels. It is a question whether a few single-screw ships with sails should not be built for distant stations.

Admiral Mills concurred with Admiral Colomb, and thought that the Admiralty were well advised in preferring 50-ton guns. The policy of large numbers is indubitably right. He had met the Russian officer in charge of the torpedo boat which blew up the Turkish vessel, and learned that his spar broke, but the Turks were so alarmed that they allowed him to tie his torpedo on to their stern and sink the vessel. Spar torpedoes can never be used in a tideway or current.

Captain Long thought sails good on a double-screw boat, but at the same time was of opinion that some ready means ought to be devised for instantly lowering or raising the sailing gear, as it is a pity to lose all the force of the wind. The only danger was, that in action a shot might cause the top hamper to fall and foul the screw.

Admiral Mayne did not agree with the author's classification. With regard to the last paragraph of the paper, he would point out that the navy must always be in position to take up an aggressive footing, but he thought there would be no new programme till after a general election. The fast merchant vessels in case of war would be used as blockade runners to carry food and supplies, so that only second-class vessels could be used for naval purposes. The great imperfection at present is the mixed armament. In the newest vessels there are eleven different kinds of guns, and that necessitates many sorts of ammunition, a fertile ground for mistakes. The guns should be capable of being man-handled in an emergency.

Admiral Morant did not believe in single-screw vessels with sails; they must be short if they are to sail well, and he doubted if other vessels were stable enough to carry sail.

Admiral Horsham drew attention to the fact that there are no coaling stations in the Pacific between Vancouver, Fiji, and the Falkland Islands, with the exception of the store-ship at Coquimbo, which could not be reckoned on in time of war.

Mr. Barnaby referred to the necessity of good boilers, especially for torpedo ships, so that they could get steam enough to go 18 knots. Larger and faster torpedo boats ought to be built.

Mr. Seaton dealt especially with the engineering side of the question of coal consumption. Auxiliary engines have doubtless much to do with the lowering of coal endurance, but there is another factor that had been overlooked. In the old days, ships went at 5 or 6 knots for economy, but this cannot be done with the modern triple-expansion engine. The valves in these engines are generally fixed so as to give the best results at a certain speed; when used at other speeds, no great economy is effected. The only way to remedy this is to carry two sets of valves, one set for low speeds, the other for high speeds.

Lord Brassey briefly replied, and said he was pleased to find that most of the speakers were in accord with him, so that he had practically no points to meet which had not been dealt with by one or other of the speakers.

(To be continued.)

THE LONDON-PARIS TELEPHONE.

The telephone cable between France and England is now successfully laid, and the first words ever spoken beneath the Channel were heard on Tuesday last. The proposal to connect Paris and London by telephone came originally from the French Administration about the time of the negotiations for the purchase of the submarine telegraphs, and it was favourably entertained by Mr. Jackson, Financial Secretary of the Treasury. Experiments, which proved the feasibility of the project, were made by Mr. W. H. Preece, F.R.S., Electrician-in-Chief of the Post Office. The Postmaster-General adopted it, and, finally, its execution was authorised by the French and British Governments. The scheme involved the construction of a trunk telephone line between the two cities, with a novel feature in the shape of a telephone cable across the Straits of Dover, the first ever made for the open sea. It was decided to have two separate circuits, so that if one should fail at any time the other might be in use. The route for the English land line was chosen by Mr. Edward Graves, the engineer-in-chief to the Post Office. It runs along the South-Eastern Railway to a point near Sidcup, and thence by road and rail through Swanley, Maidstone, and Ashford to the cable-house on the beach at St. Margaret's Bay, between Dover and Deal. The wire is of copper, and weighs 400lb. to the mile. It is nearly pure, and has a resistance of about 2·25 ohms a mile at 60° Fahr. It is supported on creosoted wooden poles, 70 yards apart, by means of double-shed porcelain insulators about 25ft. above the ground. The going and returning wires of each circuit are twisted spirally round each other all the way. The twist is made by attaching the wires to the insulators in a rotation, and the spiral is completed by each wire regaining its normal position at every fourth pole—that is to say, every 280 yards. The connection between the last pole on the chalk cliff at St. Margaret's Bay and the cable-hut on the beach is effected by lengths of the cable core enclosed in an iron pipe and buried in a trench down the face of the cliff. The whole line is eighty-five miles long, and its excellence is proved, not only by electrical tests, but by the wonderfully clear and loud speaking through it between the cable-hut and the General Post Office. The French land line follows the direct route of the Chemin de Fer du Nord, through Montdidier and Calais to the cable-house at Sangatte, between Calais and Boulogne. It is similar in construction to the English line, except that only one circuit is run at present, and the copper wire weighs about 600lb. a mile. Its length is about 204 miles. The connecting cable, which is the joint property of the two Governments, was designed by Mr. Preece, and contains four separate conductors, two for each circuit. It was manufactured by Messrs. Siemens Brothers. Each conductor is a strand of seven very pure copper wires, weighing 160lb. per nautical mile or knot, with a resistance of 7·478 to 7·632 ohms per knot at the testing temperature of 75° Fahr. It is covered with three alternate layers of Chatterton's compound and guttapercha, weighing 300lb. per knot. The total weight of each core is, therefore, 460lb. to the knot. The insulation resistance from the wire to the water is not less than 500 megohms per knot after lying in water at a temperature of 75° Fahr. for twenty-four hours before the test and after the conductor has been electrified for a minute. The capacity for induction between the wire and the water outside does not exceed 0·3045 microfarads per knot. The cores are twisted spirally round each other in a strand, so as to change places like the land wires; and to silence the cross talk as much as possible the opposite wires are meant to form part of the same circuit. The stranded cores are covered with tanned hemp, and on this cushion is laid a spiral sheathing of sixteen galvanised iron wires, each 0·28in. thick, with a breaking stress of 3,500lb. Clark's coating of mineral pitch and sand protects the whole.

On Wednesday complimentary speeches were exchanged on the new line between Mr. Raikes and M. Roche, the respective chiefs of the English and French postal services. The speaking was excellent, and Mr. Preece was generally congratulated on this latest triumph of international telephony.

A NEW ELECTRIC HOIST.

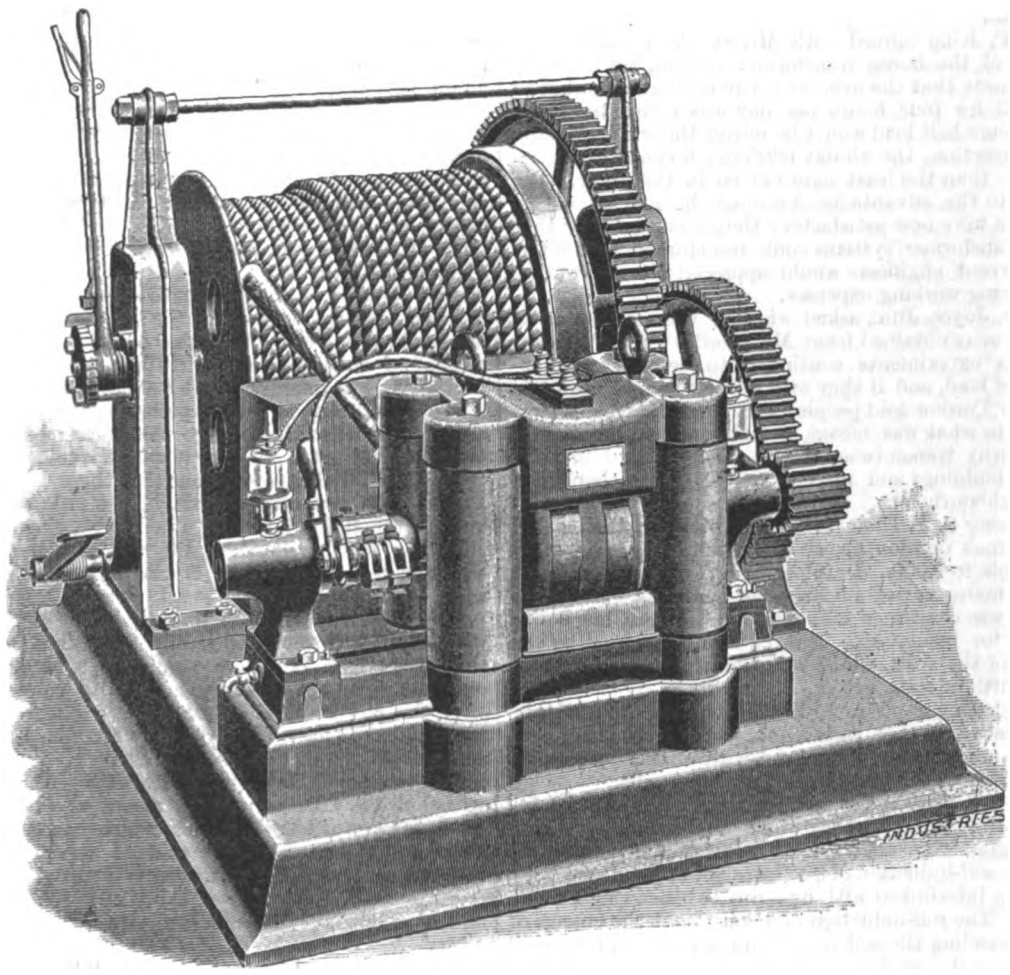
THE annexed illustration, for which we are indebted to our American contemporary the *Western Electrician*, represents an electrical hoist recently introduced by the Detroit Motor Company, of Detroit, Michigan, U.S.A. These hoists are made in two sizes of 5 and 10 horse-power, and are so designed that the levers for operating the friction clutch, switch, and brake are brought into such a position as to be easily accessible to the operator. A stout bar connects the two bearing standards at the top. This construction is to prevent any springing apart of the standards when the friction clutch is forced into place. All the parts are substantially made. The motor is provided with a raw-hide pinion, and all the gear wheels are cut to a standard. The switch and resistance box for regulating the speed are fastened to the iron bed-plate.

THE ST. PANCRAS ELECTRICAL EXHIBITION.

WE have had so many electrical and general exhibitions, that there would at first sight scarcely appear to be any opening for a local exhibition at St. Pancras. We believe, however, that the Electricity Committee of the Vestry have adopted one of the very best methods of popularising the electric light in their district; and there is little doubt that their energy will be successfully spent.

The Exhibition was opened for private view on Saturday night, when the committee invited a number of persons interested in electrical matters to meet Professor Crookes. The Exhibition was almost unique in being practically ready at the date of opening, as there were only one or stalls not quite complete, a fact which reflects great credit on the committee, who had only two days in which to transform the vestry hall into an attractive exhibition with electric cables running in all directions.

The formal opening by the Lord Mayor took place on Monday. Unfortunately, a steam valve on the portable engine employed for driving the dynamo got temporarily out of order, and the opening ceremony had to be got through by the aid of gaslight.



Most of the exhibits consisted chiefly of electric light fittings, many of the designs in brass, copper, and the fashionable wrought-iron work being very beautiful. A good number, however, of the exhibits were of a character specially interesting to the technical electrician. The gramophone, exhibited by the General Electric Company, excited the greatest interest. The room, crowded with people intently pressing tubes to the ears, looked very curious. It is no use now pointing out that such instruments as the phonograph and the graphophone are not electrical. It seems to be settled by general consent that if they are not they ought to be.

Messrs. Johnson & Phillips exhibit the Brockie-Pell arc lamp; and the visitor meets such old friends as Engelbert's lubricator; Ader telephones by Messrs. Miller & Woods; Cockburn fuses, Aron meters, Crocker-Wheeler motors, "Hedgehog" transformers, Schuckert voltmeters, and a host of other specialties by the General Electric Company; the Babcock & Wilcox boiler; Cardew voltmeters and earthing devices by Messrs. Drake & Gorham, Sunbeam lamps, and Planet arc lamps. Messrs. Ferranti exhibit a number of meters. Messrs. Drake & Gorham exhibit some battery plates of a new type. The Acme Company has a very interesting exhibit, including a large number of voltmeters and ammeters and a Teague meter. The General Electric Power and Traction Company exhibit several motors driving fans, drills, and other machinery. Messrs. Paterson & Cooper show a number of measuring instruments of various kinds, arc lamps, motors, &c. Messrs. Strode & Co. have an elaborate exhibit of fittings in a room by itself. The Key's Electric Company exhibit an interesting switchboard and various motors, and a stack of Dolivo instruments. Messrs. Lacombe & Co. have a very interesting exhibit of carbons of various sizes and shapes. Messrs. Caddy & Co. show their chilled face smoke-consuming fire-bars. Messrs. Latimer Clark, Muirhead, & Co. have a very elaborate exhibit of electrical measuring instruments of every sort, and of cables and mains.

The Vestry of St. Pancras intend to supply electrical energy at sixpence per kilowatt hour. This is a move in the right direction. As far as we know, Newcastle-on-Tyne has the lowest tariff of any, and it is to be hoped that St. Pancras will eventually be able to set an even better example of cheapness.

A NEW ELECTRIC HOIST.

CONSTRUCTED BY THE DETROIT MOTOR COMPANY, DETROIT, U.S.A.

GENERAL VIEW.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

AT a meeting of this Institution, held on the 12th inst., the discussion on Mr. Swinburne's paper, entitled "Transformer Distribution," was resumed.

Mr. A. P. Trotter said the author had been criticised for giving figures instead of facts. This criticism he considered unfair, for it was better to give figures early enough to prevent serious mistakes being made. Had Mr. Swinburne's paper on "Armature Reactions in Direct Current Dynamos" appeared sooner, it would have saved others from falling into error in making large Gramme armatures for constant current machines. On the subject of transformer tests, he said the calorimeter method, to be at all accurate, involved many troublesome corrections, and would require very large vessels. The electrostatic wattmeter methods need to be tried; "split" dynamometers neglected magnetic leakage. Mr. Mordey's thermometer method would, he thought, involve considerable trouble if anything like accurate results were to be obtained, for since the heat was in one case generated in the iron, and in the other in the copper, the fact that a thermometer on the iron gave the same reading did not necessarily show that the energy dissipated in the two cases were identical. Since the last meeting two valuable contributions to our knowledge of transformers had been read before the Physical Society. On the subject of the diminished iron losses at large loads referred to in one of these papers, he would ask whether such a result was consistent with Ewing's theory of magnetism. To him it appeared possible that the losses with rapidly alternating currents may be quite different from those existing for slow cycles. In order to illustrate the fact that physical properties of materials depend on the rapidity of the changes influencing them, he showed that a piece of pitch, which was quite soft and viscous to steady pressures, yet transmitted the rapid vibrations of a tuning fork like a rigid body.

Mr. G. C. Fricker, referring to comparisons of closed and open circuit transformers, said that in estimating the loss in a closed circuit one as 120 watts Mr. Swinburne was in full accord with writers and teachers who hold that the magnetisation is constant at all loads. This assumption was, however, challenged by Mr. Mordey at the last meeting, and he himself doubted its truth. In view of the contradictions between recognised authorities on the theory of transformers, he thought the experimental facts brought forward by Mr. Mordey should not be lightly set aside. So far as these results would affect the comparison of closed and open circuit transformers, Mr. Swinburne might say that the open form would be equally benefited if the new view be correct. He, however, could not agree to this, for the "Hedgehog" type required a very large exciting current, and hence the plant efficiency would be materially lower even during the hours of full load.

Dr. Fleming said Mr. Swinburne had ventilated his opinions against the orthodox views of parallel working, but, so far as he (Dr. Fleming) could see, he merely put forward old views under a new name. On the subject of parallel working, he thought little or no advance had been made since Mr. Mordey's paper was read. Parallel working was then shown to be quite practicable, and is now largely employed on the Continent. He could not agree with Mr. Swinburne that 1,000 volts station pressure was preferable to 2,000, for the cost of the mains in the latter case was only about half that in the former. The employment of 2,000 volts did not seem to be any more dangerous. He doubted whether the use of low-pressure alternators and step up transformers would be safer or more economical, for the waste in the transformers would be considerable, and their cost would probably far exceed the figure quoted by Mr. Swinburne. The chief claim made for the Hedgehog form of transformer was that it gave a more square-shouldered efficiency curve than the closed type. Whether this was so or not was, he said, not a question of calculation, but one on which experiment alone could decide. Such experiments should not be made by a wattmeter where a fine coil and non-inductive resistance were employed, for considerable error may be introduced. Although Mr. Swinburne admitted that the Hedgehog transformer required a large exciting current, he seemed to underrate the effect of this when a number of small transformers were connected up, for it would entail a great waste of coal and lower the plant efficiency.

Mr. Kapp thought the efficiency of the Hedgehog transformer would be increased by closing its magnetic

Digitized by Google

circuit, for this would reduce the exciting current, and, by diminishing the magnetic resistance, the lag would be increased; therefore the power would be less, and the plant efficiency greater. He could not see how it was possible for an open circuit transformer, which required a large exciting current all the day, to be more efficient than a closed circuit one. The matter could not be settled by argument, and experiment must be appealed to.

Mr. F. King agreed with Mr. Swinburne about the defects of the house transformer system, but thought his estimate that the average consumption amounted to half load for four hours per day was rather too high; three hours half load would be nearer the truth. Making this correction, the all-day efficiency becomes considerably less than the least figure given in the paper. Referring to the advantages of storage, he said secondary batteries were now satisfactory things, and believed that when transformer systems could use storage, then alternate current engineers would appreciate its importance in reducing working expenses.

Mr. S. Joyce, Jun., asked whether the iron losses in transformers obtained from Mr. Mordey's and Professor Ayrton's experiments continued to decrease with increase of load, and if they ever became zero or negative.

Major Cardew said people's opinions differed considerably as to what was meant by sub-stations; he saw no reason why transformers should not be placed in small lean-to buildings and used to supply several houses in the neighbourhood.

Professor S. P. Thompson hailed with satisfaction Mr. Swinburne's opinion about 1,000 volts being generally preferable to 2,000. Dr. Fleming had said that the cost of the mains varied inversely as the volts. As far as copper was concerned this might be correct, but it was not so for insulation. This, he thought, varied as the square of the volts, whilst compensations, &c., might be as the fifth or sixth power.

Mr. Mordey, replying to Mr. Joyce, said the efficiency curve rises and then falls again, whereas the iron losses fall to a minimum and then rise with further increase of load. Many tests had shown the same result.

Professor Ayrton did not agree with the author's remarks on Slip 4 about the word "self-induction" being meaningless when applied to an armature, and pointed out that the self-induction of a coil was not affected merely by its being interlinked with lines due to other magnetising forces. The self-induction of a coil meant the change of lines threading the coil due to unit current in that coil, and although its value would be affected by the presence of iron, yet under given conditions its meaning was quite definite. The transformer tests made by Mr. Taylor and himself had, he said, been attacked, both because they gave a point of maximum efficiency, and because they showed the loss in iron to be small at full load. No doubt Professor Ewing and Dr. Hopkinson had shown what the losses were when iron was subjected to slow changes of magnetisation, but so far as he knew there was no proof that the same losses occur with rapid reversals.

Mr. Swinburne, in replying to Mr. Esson, said the value of the self-induction given by Dr. Hopkinson referred to the maximum control of two machines of equal e.m.f. running as dynamo and motor. He then observed that, though it was said that his representative closed circuit transformer was not good enough, he had repeatedly asked for particulars of a better one, but they had not been produced. Though he had done so in his B.A. paper, he was not now called upon to design closed circuit transformers for his opponents, and in his present paper he had taken a commercial "Hedgehog" and had compared it with a commercial closed circuit transformer. His "freezing mixture" statement, he said, was not based on Ewing's curves, for he found that, according to Ferrari's tests, the loss in the whole transformer was less than the loss by resistance, and so the iron must have actually supplied power to the circuit. The readings were taken by the split dynamometer method, and proved its worthlessness. Mr. Mordey's figures were, he said, shown to be inaccurate by their agreement with those of Professor Ayrton and Mr. Taylor, which were taken by the split dynamometer method, and thus gave too high efficiency, especially at full load. Whether the iron losses become smaller or not at full load was, he said, of little importance to his contention, for if it be admitted that they are large at no load, his point as to the superiority of the open circuit type was proved. Any wattmeter would not give accurate results in transformer measurements, and before one is used it should be carefully checked both with direct and alternating currents on resistances and choking coils. Mr. Kapp's and Mr. Esson's argument that a "Hedgehog" would be improved by closing the iron circuit was, he said, bad, for that would double the iron loss. The large exciting current was not a serious matter, for, although speakers had overlooked the fact, this could be supplied by condensers or by the arrangement of a dynamo running loose.

THE PHYSICAL SOCIETY.

At a meeting of this Society, held on the 6th inst., Professor W. E. Ayrton, F.R.S., President, being in the chair, Mr. James Swinburne read a "Note on Electrostatic Wattmeters."

After referring to the history of the electrometer method of measuring power developed by alternating currents, the author pointed out that the necessity for taking two readings from which to determine the watts might be obviated by having the quadrants separate instead of connected in pairs as in the ordinary method. Non-inductive resistances are connected to the transformer, motor, or other apparatus in which the power is to be measured, so as to be in series with the apparatus and on opposite sides of it, and the four ends of these two resistances are connected with the four quadrants. Under these circumstances the deflection of the needle is a measure of the watts. To increase the maximum deflection obtainable, so as to make an instrument capable of being read by a pointer, the needle is made in two halves, fixed one below the other on the same stem, and instead of quadrants, semi-circular boxes are employed. In this way a range of about 130 degrees is obtainable.

Professor Perry, in the discussion which followed, inquired as to what kind of *law* the instrument had, and Mr. Blakesley asked whether it was convenient to use.

Mr. E. W. Smith pointed out that there was no necessity to take two observations in the ordinary electrometer method, for by using a false zero, one deflection gave the watts. Further, the use of the false zero rendered it unnecessary to employ any other voltmeter when experimenting at constant pressure.

The President said the historical part of the paper was not quite correct, and recalled attention to the fact that when high pressures were used, a single reading obtained with the ordinary method of connecting up gave the power. For ordinary low voltages, however, the false zero method described by Mr. Smith was very convenient.

Mr. Swinburne, in reply to Mr. Smith, said the observation of the false zero really meant another reading. As to the law of his wattmeter, referred to by Professor Perry and the President, he said he never calculated a law, but calibrated the instruments directly.

Professor S. P. Thompson, D.Sc., now took the chair, and a paper on "Interference with Alternating Currents," by Professor W. E. Ayrton, F.R.S., and Dr. Sumpner, was read by the latter. The paper related to the phenomena which occur when alternating electric pressures are impressed on circuits made up of various combinations of resistances, condensers, arcs, and inductive coils; to the characteristics of alternators; to the properties of transformers; and to the peculiarities exhibited by the Ferranti mains. In one of the experiments an inductive coil and a condenser were connected in series, and a pressure of 25 volts, as measured by a Cardew voltmeter, impressed on its terminals; the pressures on the two parts, measured in the same way, were 110 and 104 volts respectively, thus showing that each of the two parts was much greater than the whole. On joining a condenser and an inductive coil in parallel, an ammeter in the main circuit indicated 5·5 amperes, whilst those in the branches showed 6·4 amperes passing through the condenser and 10 amperes through the coil. Other experiments of a similar nature were described, and it was pointed out that the ratio of the sum of the two parts to the measured total may be large, being about 8 in the case first mentioned. Theoretically this rate might be anything, depending as it does on the phases of the pressures in the two parts, and these phases are determined by the ratio of the impedance of the coil to its resistance; practically, however, it was not easy to get a coil of large self-induction and very small resistance. Alternate current arcs and condensers give results of the same general character as those above described, as also do arcs and inductive coils, such as the regulating coils of lamps; this may cause considerable error in estimating the power supplied to such lamps. The magnitude of the error was found to depend greatly on the quality of the carbons and the character of the arc. With bad carbons and a hissing arc the error was very great, but with good cored carbons, burning steadily, it was not very serious. Combinations of inductive and non-inductive coils exhibit marked peculiarities, particularly if the inductive one be a transformer coil. This last arrangement gave distinct evidence of interference, or difference of phase, when the secondary of the transformer was open, but when closed, and with a moderate load, the difference of phase disappeared, thus showing that under these circumstances the primary coil has no appreciable self-induction.

On the subject of alternator characteristics, a graphical method of drawing the e.m.f. curve from the terminal curve was described, and the dependence of the terminal curves on the character of the external circuit pointed out. Keeping the speed, exciting current, and armature current constant, the pressure between the terminals was shown to be dependent on whether the external circuit consisted of condensers, resistances, or inductive coils, the pressure being greatest in the former case and least in the latter. The true e.m.f. of the dynamo, however, was the same in all the cases, but it became less as the armature current increased. From these results the authors conclude that the drop in e.m.f. with large currents is due to reaction on the field, but that the change of terminal pressure cannot be all attributed to this cause.

Transformers, it was shown, are powerful controllers of phase, for the primary and secondary currents are nearly always circulating in opposite senses; the phase angle for a 1 to 1 Mordey transformer experimented on varying from 170° at no load to 180° at full load. The relation between the strengths of the primary and secondary currents A_p and A_s was found to be a linear one, of the form $P/S\,A_p = \alpha + \beta\,A_s$, where P and S are the numbers of turns in the primary and secondary respectively, and α and β constants, α representing the exciting current and β being nearly unity. The phase angle ϕ between the currents was given by the equation—

$$-\cos\phi = \frac{\frac{1+\beta^2}{2}A_s + \alpha\beta}{\beta A_s + \alpha}$$

The results of numerous experiments on a transformer of the Mordey type, in which coils having different numbers of turns were put in parallel with each other, were given. In some cases resistances were put in circuit with the coils, and in others one or more of these resistances were cut out. Remarkable interference effects were thus produced, for in some combinations the volts or currents were additive, whilst in others they were nearly differential. In connection with the "Ferranti effect," experiments had been made by putting a condenser on the terminals of the secondary of a transformer, and noting the resulting increases in pressure both in the primary and secondary circuits. The results obtained with a given condenser and approximately constant secondary pressure show—(1) That whether the transformation be up or down, the percentage rise in the secondary is greater than that in the primary; (2) that these percentage rises diminish as the secondary current increases; (3) that they increase with the ratio of transformation; (4) that the rise in the secondary may be considerable without that in the primary being appreciable; (5) that the rise in the secondary still persists, even when large currents are flowing.

These facts lead the authors to believe that the Ferranti effect is due to some kind of interaction between the cable condenser and the self-induction of the transformer, and that it is not wholly due to armature reactions in the dynamo.

In the discussion on the paper, Mr. Swinburne said the character of the Ferranti effect had been wrongly stated, for he understood Professor Ayrton to say that the pressure in the Ferranti mains was greater at the London end than at Deptford. This, he contended, was impossible. He also said the effects now described, of putting a condenser on the secondary of a transformer, and noticing the rise in both primary and secondary volts, were due to the waste field of the transformer. In large transformers, such as those at Deptford, the magnetic leakage was proportionately much less, and no such effects would be noticeable with them. Referring to the relation between the primary and secondary currents in transformers, he said it was convenient to look at the primary from two points of view, and consider one part of it as producing the magnetisation, and the other as neutralising the effect of the secondary current.

Mr. Mordey described an experiment on armature reactions in alternators, in which one of the armature coils of a 50 horse-power machine was isolated from the rest and connected directly to a Cardew voltmeter. On varying the load from 0 to the full output (20 amperes), the voltmeter on the isolated coil was quite stationary, thus showing that no appreciable armature reaction occurred.

Mr. E. W. Smith remarked that the formula connecting the primary and secondary currents holds true over a very wide range, for he had experimented on a Kapp transformer, which gave (α) constant and (β) = 1 for frequencies varying from 20 to 200.

Mr. Blakesley gave the following formula as applying to transformer currents generally—

$$\left(\frac{Ar}{As}\right)^2 = \frac{n^2}{m^2}\left\{(1+kr_2^2) + \frac{q r_2^2}{v}\right\}$$ where r_2 = resistance

of secondary, v is proportional to the frequency, m and n the primary and secondary turns, and k and q are constants depending on the disposition of the iron. This formula he found to very nearly represent Ferrari's results, and he hoped others would test its applicability to various types of transformers. He believed himself

Digitized by Google

to be the first who carried out an interference experiment, when he put a condenser in parallel with an inductive coil six years ago. He mentioned the matter now, because that arrangement had been put forward by Mr. Glazebrook in explanation of the "Ferranti effect. Mr. Glazebrook, however, had made an error in stating that, under certain conditions, one of the currents may become infinite.

Dr. Thompson thought the word interference had been used in a somewhat different sense to its ordinary usage in optics, and asked for an authoritative definition of its meaning in the paper under discussion. The experiments on the alternating arc he considered very remarkable, as well as those on the dynamo, which give various terminal pressures when its e.m.f. and current were the same, but the external circuit of different character.

Professor Ayrton pointed out that the measurements on the rise of volts by putting on condensers mentioned in the paper were not strictly analogous to those made by Mr. Ferranti, for his were made by pilot transformers, one placed between the primary terminals of the Deptford transformer, and the other on the secondary of the London transformer, whereas in the cases now brought forward the volts measured were those at the primary and secondary of the same transformer. On the subject of arc lamps, he said that Messrs. Kolkhorst, Thornton, and Weekes, who made the experiments, found that great lag only occurred when the carbons were bad and the arc hissing. If the apparent and the true power spent in such an arc were measured, a great difference existed between them. Dr. Hopkinson, he said, had shown that this might be expected if the arc had a constant back e.m.f. which changed sign with the direction of the current.

A paper on "The Theory of Dissociation into Ions and its Consequences," by Professor S. U. Pickering, F.R.S., and another on "Some Points in Electrolysis," by Mr. J. Swinburne, were postponed.

Referring to the meeting held on the 27th ult., the transformer on which the tests described in Professor Ayrton's and Mr. Taylor's paper were made was of the Mordey type, having been kindly lent by the Brush Electrical Engineering Corporation.

MODERN CHEMISTRY IN ITS RELATION TO SANITATION.

Dr. Tidy, in his second lecture at the Royal Institution, on the 12th inst., proceeded to show that whereas the three natural disinfectants of air, water, and earth were adequate for primitive times, the conditions of advanced civilisation necessitated the supplementing of nature's processes by the use of disinfectants made by man, and by their employment an endeavour was made to counterbalance the unnatural conditions of life in large towns. Water, the second of the natural disinfectants, acts like air, both being mechanical and chemical agents. A good shower of rain, by washing the air, has often been the turning point in the history of an epidemic. Although the cleansing power of running water is considerable, local authorities and engineers have probably in the past relied too much on the mechanical systems of cleansing, as infection was often so subtle that chemical agents alone were capable of destroying its power. As our rivers have thus been utilised for the removal of pollution by the drainage systems of towns situated on their banks, a question of considerable importance arises as to probable pollution and infection of the water supply of towns situate lower down such streams. The efficacy of filtration is, however, very remarkable in purifying a river before use as a water supply for a town, and the enormous dilution of the sewage, the rapidity of the flow, the length of run, and the presence of vegetable life in the river are all important factors in bringing about the removal of any impurities which may be introduced.

Sewage in suspension is also considerably removed by subsidence, whilst the presence of animal life and the direct oxidation of the organic matter by the dissolved air further tend to reduce possible dangers to a minimum. In most river waters there are 2 cubic inches of oxygen dissolved in every gallon, and it is easy, by Schutzenberger's method, to estimate its amount. Running water also very rapidly absorbs oxygen from the air if any causes have been at work to remove it from the water, and thus a river acts as a carrier of the oxygen of the air to the organic matter, and brings about its oxidation. In most rivers an inspection of the condition of the bed and banks for some distance below a sewage outfall is sufficient to demonstrate the rapidity with which such pollution is removed by these agencies, and Dr. Tidy, some years ago, further showed by direct experiment that, in a run of one mile in an artificial channel, the oxygen in polluted water was reduced from 100 to 38 by the oxidation of the organic matter present, which fell from 100 to 53 by the oxidation. Fish and vegetation in a river must considerably augment this rate of removal, and, although the experiments only indicated the rapid destruction of the organic matter, there can be no doubt that the real infection due to the spores or bacteria present is at the same time removed. In conjunction with Professor Odling and Mr. Crookes, the lecturer has also established the fact that bacteria when introduced into distilled water or Thames water die in a few hours, and in no case could any living bacteria or growth be recognised after an interval of six hours. It has further been noticed that in cholera epidemics there has never been, with possibly one exception, an outbreak which followed the flow of the river, so that the self-purification of water renders it one of nature's most useful disinfectants. The disinfecting power of earth is generally acknowledged, and the outcry against graveyards is probably much exaggerated. The deodorising properties of earth are well known, its action being similar to the absorption of ammonia by charcoal, and to that of a platinum wire, which, when dry and warm, coerces the chemical union between the oxygen of the air and coal gas. Earth also contains organisms which have the special function of bringing about the destruction or oxidation of organic matter, ammonia being converted into nitrates in this way.

An artificial disinfectant may be defined as a chemical which prevents or destroys hurtful things or things which cause offence to the sense of smell. There are, however, many dangerous fallacies in their use, and the unblushing quackery which exists in the manufacture and sale of many renders it important to be able to test the efficacy and relative merits of such artificial disinfectants. They may be divided into four classes—(1) Those which prevent decay, *e.g.*, refrigeration; (2) those which assist decay, *e.g.*, Condy's fluid; (3) those which hurry it on; and (4) special agents. In concluding, Dr. Tidy sketched the changes which increase of knowledge had caused in the methods for increasing the efficacy of artificial disinfectants.

SEWAGE TREATMENT.

On the 3rd inst. a lecture was given by Mr. G. E. Davis, in the Manchester Technical Laboratory, in which he described his new process of sewage treatment. At the opening of his lecture Mr. Davis referred to the growing importance of the sewage question from a sanitary point of view. Treatment of sewage matter was easier when the storm water was kept separate from the sewage proper by the "Menzies" or "separate system" of sewers. This arrangement, however, was not generally adopted, on account of expense. Refuse from chemical and other works, together with organic matter and road detritus, were all found in sewage. The Salford sewage possessed a daily volume of 10,000,000 gallons, which would produce per day:—

Suspended matters, mineral	2·0	tons.
" " organic	3·5	"
Total soluble solids	58·0	"
Total hardness	7·7	"
Chlorine	19·9	"
Alkalinity	11·2	"
Total ammonia	0·9	"
Iron	0·4	"
Lime	5·6	"
Soluble organic matter	13·5	"

The above would give an idea of the quantities to be dealt with in a works such as Salford. The soluble organic matter was the most important impurity to be dealt with. It consisted of complex nitrogenous matters, which, however, were easily decomposed by many metallic bodies and also alkalies, to form innocuous compounds.

The complete clarification of sewage by subsidence alone was impossible on account of its glutinous nature; for the same reason continuous filtration could not be employed. The soluble organic matter of such a sewage as Salford was slowly oxidised by the atmosphere; the author calculated that 7¾ tons of oxygen, or 1,000,000 cubic feet of air daily, would be required to oxidise the sewage to a safe point. When the crude sewage of large towns passed into a river it combined with the road detritus to form a silt at the mouth of the river. The Tyne at Newcastle, the Humber at Hull, the Thames at Gravesend, the Itchen at Southampton, and the Mersey at Seacombe were quoted as examples of this. In a paper in the *Archæological Journal* for 1885 an account was given of the manufacture of Portland cement from the above river deposits after they had been mixed with chalk.

Coming to the pecuniary inducements to the treatment of sewage, the author said that most inventors had had an eye to extracting hidden wealth in the shape of ammonia and phosphates. The nitrogen contents of the Salford sewage were equal to 3 tons of ammonium sulphate daily, or a yearly value of £11,000, and yet there was no process worked which would extract that ammonia economically. The problem of extracting ¾ of a ton of ammonia from 50,000 tons of water was no easy task. The ammonia was principally found in the soluble portion of the sewage—a fact which had been in a great measure overlooked by those expectant of profits. Some inventors seemed to think that there was a mine of wealth in the sludge, but, in the author's opinion, its use as a manure had better be left out of account, as its fertilising ingredients could only be practically of use in irrigation processes. The various processes of sewage treatment in actual use might be classified as:—(1) Filtration Processes.—Irrigation was essentially the most rational of all filtration processes. He did not think that raw sewage should be applied to land, but, wherever possible, the effluent from a precipitation process should be put on land, as the value of sewage as a fertiliser lay in the effluent. As in fresh sewage more than half the albumenoids were insoluble, filtration would remove these as well as the suspended matters, but filtration was attended with many practical difficulties. (2) Oxidation and Reduction Processes.—The least expensive method was to blow air through. The Salford sewage, as he had already pointed out, required theoretically the oxygen of 1,000,000 cubic feet of air daily, but, judging from other applications of blast, he estimated that it would require sixteen times that amount in practice, and he had calculated the cost of aëration on that basis. No doubt aëration was useful, and Dr. Angus Smith had suggested that probably a combination of the lime process with aëration would be the best that could be adopted. Another method of aëration consisted in running the liquid down a packed tower against a current of air. Bleaching powder, if used as an oxidant, would cost Salford £200,000 yearly. Manganates and permanganates, if used in sufficient quantities for complete oxidation, would be far too expensive, and in insufficient quantity were of no use. (3) Precipitation Processes.—He would not attempt to deal with the large number of processes in this section, but wished to point out clearly that the action was in all cases a chemical one, and failure would result if the proper portion of precipitant was not used. Owing to the cost of chemicals, and to the difficulty of disposing of the sludge, most of these processes were failures. The chief faults of the lime process as at present carried out were that, if only a small quantity of lime was used, it was all seized upon by the carbonic acid in the water, and very little purification was effected. On the addition of more lime, say 18 cwt. per million gallons, some of the soluble organic matter was acted upon, but, as he showed by some analyses of the Leeds sewage, complete purification was not effected until 2 tons of lime had been added. The peculiar odour of the effluent was completely destroyed by aëration, and a clear liquid resulted. This, however, was highly alkaline, and, therefore, an objectionable liquid to enter a stream. The present tendency was to keep down the amount of sludge formed which was in proportion to the lime used, but if the sludge could be turned to profitable account the case would be different. He claimed that by a combined lime and aëration process he had succeeded in—

(1) Removing the whole of the insoluble albumenoids;
(2) Removing 45 per cent. of the soluble albumenoids;
(3) Completely deodorising the affluent;
(4) Restoring the neutrality of the effluent; and
(5) Utilising the sludge at a profit.

The processes were shortly as follows:—The lime is added in two lots: in the first mixer about 7 cwt. per million gallons are added to combine with the carbonic acid; in a second mixer 33 cwt. more lime is added. The mixture then flows through a series of settling tanks, a clear effluent being obtained. This now passes into a chamber, where it is treated with a current of air and carbonic acid. Here the organic odours are oxidised and the excess of lime precipitated as carbonate. If the sewage is strong in ammonia the gases from this chamber are passed through a packed scrubber moistened with sulphuric acid, and the ammonia is recovered as sulphate. The effluent from the precipitated carbonate of lime is quite neutral, free from odour, and unalterable in the air. The sludge, after being mixed with the proper proportion of silicate of alumina, is made into Portland cement. It is first dried in a chamber by the waste heat coming from the cement kiln, which is built alongside. The heat passing over the sludge dries it and takes up ammonia, which is recovered in an acid tower through which the gases pass. The gases from this chamber contain quite enough carbonic acid derived from the coke and chalk of the kiln to carbonate the lime as above described. The carbonic acid is thus obtained for nothing, and is used over and over again.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

At a meeting held on the 16th inst. Mr. W. Crowder read a paper entitled "Observations made in the Working of Vitriol Chambers," in which he gave details of the actual working of his own plant, consisting of a series of four chambers, extending over a long interval of time. The paper was arranged so as to show the variation of yield of acid in the different chambers under the varying conditions of ordinary working, and illustrated the close relationship which exists between the diurnal atmospheric temperature variations and the quantity of acid produced per diem. The composition of the gases in the towers and chambers was also traced, showing the gradual diminution in the quantity of sulphurous acid in the progress of the gases through the plant, and the author confirmed in many points the observations of previous investigators on the necessary conditions required for the successful economic working of a well-equipped vitriol plant.

Mr. Tyrer, in moving a vote of thanks to the author for his paper, drew attention to the enormous amount of labour entailed in obtaining daily statistics for so long a period, and hoped that the author, by availing himself of the conclusions which his average yields indicated, would be able to compete successfully in these days of trade rivalry in the manufacture of vitriol.

Mr. A. H. Allen next read a paper on "The Chemistry of Whisky and Allied Products," in which he gave an outline of the Scotch and Irish whisky industry, and pointed out the essential chemical differences in that produced by pot stills and the silent spirit of patent stills. In Scotland pure malt only is employed in the pot stills, whilst in Ireland a mixture of malt and unmalted grain is used. No less than 1,739 illicit stills were discovered in Ireland during last year, but it is noteworthy that Scotland and England are comparatively free from seriously following this illegal industry. The one point of interest in the paper was the allusion to the utilisation of the pot ale and spent malt for agricultural purposes, regarding which Mr. Cross, in the discussion which followed, stated that in America the pot ale was being utilised for the preparation of lactic acid on a commercial scale, and that, being an alcoholic acid, it would no doubt be found a valuable substance in the dyeing and calico printing industries. The author next referred to the methods employed for the estimation of fusel oil in whiskies and allied products, with especial reference to the recent work of the House of Commons inquiry on this subject. He pointed out that although on the Continent much work had been done in this direction, in England, before the inquiry was started last year, a few analyses by Dupré were practically the only information on the amount of fusel oil in British whiskies, and that some of the more recent determinations were misleading, as the analysts had made no allowance for the ethers present in the spirit, which, if not decomposed, are absorbed by chloroform, and thus raise the apparent quantity of fusel oil returned as present in the whisky. This error gives results which in many cases do not show the gradual removal of the fusel oil from the whisky by ageing, but by treating the spirit with caustic potash before estimating the fusel oil the ethereal compounds present are broken up, and the difficulty is overcome. As a result of his recent work, he concludes that Irish and Scotch whiskies contain a much smaller quantity of fusel oil than is found in many Continental spirits, that ageing in wooden casks considerably diminishes the small quantity present, and that even as much as 2 per cent. of fusel oil has no injurious effect, although it imparts a very nauseous taste to the spirit. The author believes that the deleterious effects of new and raw whiskies is probably due to some other compound present in such spirits, and hopes shortly to communicate further information on these points.

Notes.

THE LAKE OF GENEVA.

Some researches have recently been made by M. Delebecque, a French engineer, into the physical features of the Lakes of Geneva and Annecy, and have been communicated by him to the Paris Academy of Sciences. A more complete knowledge of the Lake of Geneva has thus been obtained, according to which a map on the scale of 1-25,000th has been constructed. The lake is divided into two unequal parts by an elevation of its bed known as the bar of Nernier or Promenthoux, corresponding to the sudden contraction of width from east to west, which separates the Grand Lac, prolonged towards the Alps, from the Petit Lac, which runs in the direction of the Jura. The maximum depth of the Grand Lac, between Evian and Ouchy, is 1,017ft., and its bed forms a large plain with very little slope. Over a surface of about 18 square miles the variation in level is not more than 16½ft. The inclination of the lateral slopes varies from between 1 deg. and 2 deg. in the Bays of Rolle and Condrée to 56 deg. at the Castle of Chillon. The Petit Lac consists of four small basins, with a maximum depth of 249ft., separated by flattened bars. Opposite Bellerive, and from a depth of 82ft., rises a little hill, the top of which is only 26ft. below the surface. Other peculiarities of the lake-bed which have been noticed by previous observers are the ravine of the Rhone and the delta of the Dranse, a characteristic type of torrential deltas. The ravine of the Rhone has been traced for nearly four miles from where the river enters the lake, and is from 300ft. to 500ft. in width. The surface of the lake is 224 square miles in extent; its volume, 89 milliards of cubic metres; and its mean depth, 429ft.

THE LONDON ELECTRIC SUPPLY CORPORATION.

The report of Mr. Ferranti, the engineer to the above-named Corporation, as to the present position of the undertaking is, on the whole, very satisfactory. The mains are working well, and the difficulties in insulating 10,000 volts seem to have been illusory. In fact the Oërlikon Company now proposes to transmit power at 30,000 volts. The engines and dynamos at Deptford are working, and parallel running has been found to be possible, which is a great advantage. We also hear little of disturbances of the telephone systems, and other difficulties seem to be rapidly melting away. There are eighteen miles of concentric cable now in use, and carrying capacity enough to supply 300,000 lights, or more than three times the present output.

A CURIOUS EXPERIMENT.

During the discussion at the Institution of Electrical Engineers last Thursday, Mr. A. P. Trotter showed a very curious experiment. The vibrations of a tuning fork were transmitted by a piece of pitch without being sensibly diminished by its viscosity. The discussion on loss by hysteresis in iron must not be extended indefinitely, but, without going into Mr. Trotter's deductions from his experiment, a curious phenomenon that can be observed in "Willoughby Smith" may be mentioned. If a stick of this compound be bent, it will gradually straighten itself again. If it is first bent in one direction, say to the right, and is then quickly bent to the left, it will first unbend its last bend by moving to the right, and will then stop, and finally move to the left to undo the effects of the first bending. Of course "Willoughby Smith," or as it is generally erroneously called, "Chatterton," is not really viscous like pitch or marine glue; the rubber or gutta percha in its composition seems to retain its properties to a great extent.

THE PRINCE OF MONACO'S YACHT.

The electric lighting of the Prince of Monaco's yacht "Princess Alice" has been placed in the hands of Messrs. Woodhouse & Rawson United, Limited, electrical and mechanical engineers, 88, Queen Victoria Street, London, E.C. The engine is of the single-cylinder vertical type, running at from 200 to 250 revolutions per minute, according to the e.m.f. required, with a steam pressure of 150lb., and is provided with an extended bed-plate for receiving the dynamo, which is coupled direct to the engine, and gives, when running at 250 revolutions per minute, current for 100 16 c.p. lamps at an e.m.f. of 135 volts, this particular e.m.f. being provided to allow of charging the accumulators. The number of lamps installed throughout the yacht will be about 100, the fittings being of an elaborate description, and designed specially for this installation. The whole of the arrangements are not yet completed, but in all probability there will be provided a set of accumulators, a projector, and also a powerful submarine arc lamp for carrying on scientific observations at night.

COAL MINING IN CHINA.

The supply of coal from Japan, which is obtained for the use of foreign steamers, is now an important factor in Eastern trade, while the quantities exported to China and the Australian colonies are very considerable. The Chinese have done something in the way of supplying themselves with coal from their own resources, but only in a small and very imperfect manner. Attention is now, however, being paid to the subject, and in various districts attempts are being made to develop the coal supplies. The Viceroy of Liang Hu Provinces has issued a proclamation in which after pointing out the great uses of coal to manufacturers he announces his attention of using no foreign coal in future for any of the schemes which the Government have in hand, but to depend entirely on the native supply. He has evidently been prospecting and experimenting, and also making calculations as to the probable amount to be required in the near future in the private and Government factories, and by the steamship companies. In his proclamation he says, "I will take all the coal, whether hard or soft, you can bring me, and, in case I cannot use it myself, I will guarantee to find a market for the surplus. Hitherto the mines have not been properly or profitably worked. You only got at the surface coal, and could not keep the water out of the shafts when they were sunk to any depth. To remedy this you must purchase foreign pumps, which you can work yourselves, as the gear and working are very simple."

PRODUCTION OF PRECIOUS METALS IN THE UNITED STATES.

The Director of the United States Mint, in his annual report, states that during 1890 the gold product of the country was 1,588,880oz., of the value of £6,569,000, an increase of £9,000 over the product of the preceding year. The silver produced from the mines was about 54,500,000oz., an increase of 4,500,000oz. At the average price of silver during the year the product would be worth £11,445,000. The amount of silver offered to the Government was 68,130,457oz., and the amount purchased 37,594,373oz., at a cost of £7,998,300. The amount of precious metals used in the arts in the United States is returned as:—Gold, £3,621,100; silver, £1,846,200. The coinage of the year was:—Gold, £4,093,000; silver, £7,608,000. The metallic stock of the country was approximately on January 1, 1891:—Gold, £140,919,800; silver, £97,309,000.

CULTIVATION OF TOBACCO IN NEW SOUTH WALES.

The following information as to the cultivation of tobacco in New South Wales has recently been supplied to the London Chamber of Commerce by the Newcastle (N.S.W.) Chamber of Commerce:—"Both the soil and climate of New South Wales are admirably adapted for the growth of tobacco leaf. Special knowledge, however, is required on the part of the growers, in order that proper cultivation may result, and probably for this reason a larger quantity is not grown. From reliable statistics we ascertain that in the year 1862 there were only 224 acres under cultivation, which produced 2,467 cwt. of leaf tobacco, but in the year 1888 the area had increased to 2,371 acres, yielding 23,465 cwt. of leaf tobacco. The growth of tobacco leaf seems confined principally to the agricultural districts of Argyle, the Hunter Valley, and Tumut, a very large quantity being grown in the latter district, chiefly by Chinese, who seem to be well skilled in its cultivation and the preparation of the leaf. It may be observed that the quantity of colonial-grown leaf used in the colony now amounts to about three-fourths of the total consumption."

FERROID, A NEW ARTIFICIAL STONE.

Mr. Herman Poole describes in the *Journal of the Association of Engineering Societies* a new artificial stone, which is a compound, partly chemical and partly mechanical, of iron, sulphur, and silicon, with more or less foreign matter. It is mainly a supersaturated solution of iron, the sulphur with the silica acting as a binder and hardener. Its normal colour is a dark slate, varying somewhat with the manner in which it is dressed, but the colour can be somewhat modified by the introduction of pigments. Successful imitations of various coloured brick and sandstone have been made. It is about the hardness of ordinary bluestone and can be worked by the usual stone cutting tools, turned in a lathe or planed. The tensile strength is from 650lb. to 1,200lb. per square inch, and under compression it endures from 9,000lb. to 12,000lb. Its specific gravity is about 2·6. It melts at about 300° Fahr. very slowly. It does not deteriorate under exposure to the weather. As it can be melted and moulded, it is applicable to a great variety of uses to which stone cannot be put, and particularly so for large castings, such as pipes for sewage, &c. Architectural forms can be very conveniently made from it in position if needed. For culverts and bridge foundations, the perfect smoothness, of which the surface is susceptible is advantageous in lessening water friction.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

2nd March, 1891.

3695. Higginson, J., Jun. ..... Apparatus for grinding the flats of revolving flat carding engines.
3697. Laidlaw, J. ..... Machine for forming solid bars into helices.
3698. Garforth, W. ..... Air pump.
3700. Reynolds, W. F. ..... Gearing brackets employed in spinning, twisting, doubling, preparing, and similar frames.
3706. Muckley, D. ..... Process and machinery for the manufacture of tubes.
3710. Melichar, J. ..... Steam ploughing machine.
3712. Webb, F. W. ..... Locomotive boilers.
3714. Swayne, G. ..... Feed slide clearing machine.
3717. McNaught & McNaught Valve mechanism for steam engines.
3723. Smith & Baker ..... Box binding and staying machines.
3729. Hora & Hora ..... Machinery for bending metal bars for tyres.
3733. Tully, W. ..... Steam engine governors.
3735. Perry & Armstrong ... Apparatus for indicating the steering course of vessels.
3736. Blake & Barclay ..... Sugar-cane mills.
3738. Marx, J. ..... Apparatus for electrolysing and bleaching.
3744. Snell, H. S. ..... Hydraulic traps.
3752. Attenborough, E. ..... Straight-bar knitting machines.

3rd March, 1891.

3767. Marsily, W. E. ..... Constant and continuous pressure and velocity generator for fluids.
3773. Wiseman, E. ..... Railway signalling apparatus.
3787. Harris, C. ..... Screw steamship.
3788. Robinson, S. W. ..... Apparatus for producing and inserting metallic nails.
3793. Braurach, E. A. ..... Steam boilers.
3795. Cunliffe & Barlow ... Rotary fans.
3803. Hussey, McCann, & Hatch ..... Grease separator for steam engines.
3808. Tooth, Harris, & Harris Mowing and reaping machines.
3811. Taylor & Lowe ..... Gas-fired steam boilers.
3815. Acland & Holmström ... Breech mechanism of quick-firing guns.
3830. Priestman & Priestman Hydrocarburetted air engines.
3836. Newton, H. E. ..... Surface condensers (*Worthington*).
3840. Massey, A. P. ..... Automatic valves for air brakes.
3850. Walker & Theerman ... Direct-acting steam pumping machinery.
3851. Sponsel, C. W. ..... Breechloading ordnance.

4th March, 1891.

3852. Chadwick, L. ..... Steam engine pistons.
3865. Jefferson, W. ..... Davits for lowering ships' boats.
3872. Fielding & Fielding ... Apparatus for winding back the warp beam in looms and for maintaining the tension of the warp.
3885. Craig, G. ..... Coal-washing machine.
3897. Pickup, Byrom, & Dransfield ..... Fans.
3913. Blackman, A. E. ..... Rotary engines.
3914. Hall-Brown, E. ..... Feed water and heating apparatus for steam boilers.
3918. Lane & Lane ..... Punching machines.
3922. Horn, W. W. ..... Grinding mill (*Poulin*).
3927. Basset, W. B. ..... Apparatus for controlling power-operated steering gear.

5th March, 1891.

3934. Bell, W. ..... Lowering, raising, and detaching gear for ships' boats.
3943. Menzies, J. ..... Piston packing rings.
3948. Trewhella, J. ..... Gas engines.
3959. Cracknell, R. J. ..... Ice-making machines.
3981. Duesberg-Delrez, M. ... Manufacture of card teeth and apparatus therefor.
3983. Clarke, E. F. ..... Rotary fluid meter.
3988. Lake, H. H. ..... Presses (*Hull*).
3990. Stevenson, A. ..... Boiler furnaces.
3994. Clarke, E. F. ..... Rotary engine.
3999. Barton, J. B. ..... Machinery for making seamless tubular lining for hose pipes (*Foote*).

6th March, 1891.

4004. Dawes, A. ..... Starting apparatus for gas engines.
4024. Fenby, H. P. ..... Hydraulic valves.
4035. Booth & Pickersgill ... Apparatus for drilling the flanges of boiler flues.
4039. Hookham, G. ..... Tools for forging steel shells.
4050. Mannesmann, M. ..... Apparatus for forming, rolling, and calibrating metals.
4051. Blaxton, W. J. ..... Frictional speed reducing gear.
4056. Woodward & Shaw ..... Straight bar knitting machines.
4066. Rothwell, F. ..... Screw down taps.
4073. Wild, E. J. ..... Rotary fans.

7th March, 1891.

4078. Moorhouse, S. ..... Water gauges.
4079. Fleming, Ferguson, & Dixon ..... Motive power engines.
4085. Norman, R. A. ..... Grinding mills.
4089. Munns, W. H. ..... Crushing mill (*Olsen*).
4109. Burton, W. ..... Presses for drawing through and forming up sheet metals.
4112. Combe, A. ..... Twisting frames.
4122. Wilson & Vogel ..... Excavating machinery.
4125. Lycett, E. ..... Crushing and grinding mills.
4132. Johnson, T. W. ..... Apparatus for annealing copper wire and sheets.
4139. Bonne, C. R. ..... Warp looms (*Kreissig, Sonntag, Jun., & Hartig*).
4141. Schmitz, J. ..... Carding engines.
4142. Priestman & Priestman Hydrocarburetted air engines.
4143. Lux, F. ..... Gas engines.

ELECTRICITY.

2nd March, 1891.

3694. Webb & Thompson ..... Switches.
3740. Koechlin, M. ..... Electric meters.
3755. Dukes, B. ..... Automatic switches (*Heil*).

3rd March, 1891.

3765. Buchanan, L. H. ..... Arc lamps.
3799. Clark, A. ..... Electric battery solution.

4th March, 1891.

3867. Kennedy, R. ..... Electricity meters.
3895. Corning, F. G. ..... Apparatus for transferring electric car batteries. (5th August, 1890.)
3904. Richards, T. P. ..... Switches.

5th March, 1891.

3957. Miller & Woods ..... Electricity meters.
3967. Coad, T. ..... Electric safety lamps.
3984. Patin, O. ..... Arc lamps.

6th March, 1891.

4005. Bryan, F. ..... Dynamos.
4044. Simpson, R. H. ..... Accumulators.
4064. Hookham, G. ..... Electricity meters.

7th March, 1891.

4099. Akester, W. H. ..... Arc lamps.
4120. Fryer, W. J. ..... Incandescent lamps.

CHEMISTRY.

5th March, 1891.

19942A. Thompson, W. P. ..... Electro-chemical formation of chlorine and chlorine compounds (*Marx*). (6th December, 1890.)

3rd March, 1891.

3832. Noad, J. H. ..... Manufacture of white lead.

4th March, 1891.

3887. Hedley, G. H. ..... Manufacture of red oxide of iron.
3925. Ellershausen, F. ..... Treatment of soda waste.

6th March, 1891.

4068. Lyte, F. M. ..... Production of chlorine.

MISCELLANEOUS.

3rd March, 1891.

3771. Harvey, H. N. ..... Shaft couplings.
3819. Pollard, T. P. ..... Nut lock.

4th March, 1891.

3886. Nasmith, J. ..... Method of cutting the teeth of wheels.

5th March, 1891.

3992. Vautin, C. T. J. ..... Hydro-metallurgical method of extracting gold or platinum from their ores.
3993. Ibbotson, A. B. ..... Railway fish plates.

7th March, 1891.

4146. Hansell, R. B. ..... Casting ingots for the manufacture of weldless tyres, bars, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

3304. Greenhill.
3503. Williams.
3632. Taylor.
3434. Mayer.
3583. Lindner.
3661. Jones.
3752. Thomson.
3790. Laumann.
3802. Jaensch.
3883. Whitfield.
3994. Anderson.
4037. Clarkson & Spurge.
4062. Charles Graham Grant.
4118. Shaw.
4216. Tipping.
4337. Bolton.
4376. Young & Young.
4394. Ricard.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Drilling Machines.—*J. J. Weatherburn, Gateshead, Durham.*—The inventor's aim is to provide an automatic feed motion for advancing the drill or other tool of a drilling machine whilst drilling, or tapping holes. An apparatus of this description is shown in the accompanying illustrations, of which Fig. 1 is a side elevation and Fig. 2 a front sectional elevation. A is a friction clutch into which the tapered end of the hollow screw B fits. C is a spindle, the lower end of which is secured to the tool box D, and between the said box and the hollow screw B is a spring E of suitable strength. F are washers separating the spring E from the screw and drill box. The upper end of the spindle in which is the slot G is square, so that the friction clutch revolves with the spindle. H is a set bolt and I a key, arranged as shown, so that by tightening up the set bolt the friction clutch can engage with the coned end of screw B, and also compress the spring E. The screw B works in a nut J, arranged in any suitable position, as on the end of the arm of an ordinary drill stand K. The action is as follows:—The set bolt

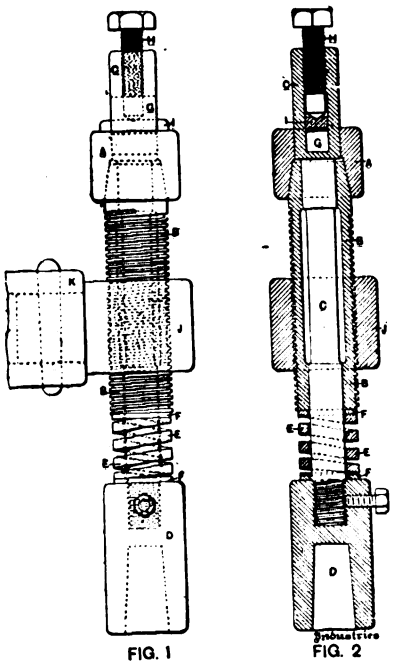

FIG. 1

FIG. 2

H being set so as to give the required amount of pressure to the spring, the spindle C, and with it the screw B, is rotated. The tool running light under these conditions advances a distance equal to the pitch of the screw B per revolution. Suppose the screw has ten threads per inch, and revolves 100 revolutions per minute, and the tool advances $\frac{1}{100}$in. per revolution to its work, then the difference in advance of the tool and screw per revolution tends to equal $\frac{1}{10}$in. minus $\frac{1}{100}$in., which difference takes effect in relieving the pressure of the set bolt H on the key I, which in turn relieves the pressure between the coned end of the screw B and friction clutch, and the instant this pressure is thus relieved the spring E with the lower end of screw B as an abutment continues the forward motion of the tool box and tool, thus affecting the automatic feed required, and causing the clutch and screw to again engage, when the above operations are repeated. The invention also comprises a structural modification of the above. In four claims the inventor embraces the general arrangement of an automatic spring feed motion as described, with modifications. —No. 12,449. August 9th, 1890. 8*d*.

Machinery for Finishing Splayed Cotters.—*A. F. Busby, Birmingham.*—The present invention relates to machinery for forming the ends of splayed cotters with an inclined portion, and also bending said ends towards their rounded sides. In the accompanying illustrations, Figs. 1 and 2 show respectively a side sectional elevation and a plan of a machine for the above purpose, and Fig. 3 the front and side elevation of a finished cotter. Formed in the face of a stationary die A fixed in the tool box B, secured to the table C, is a deep groove, the back of which is shaped to the form the cotter is to be pressed. Sliding in the tool box B, one above the other, are the slide D for holding the cotter in the groove in A and a second slide E for pressing the end of the cotter so as to force it against the end of said slot, so bevelling and bending the end thereof at one operation. These slides, held in D by a plate D^1, are actuated as shown (Fig. 1) from a crank-shaft F, the return motion being caused by springs

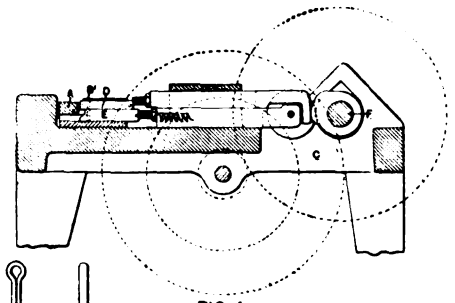

FIG. 1

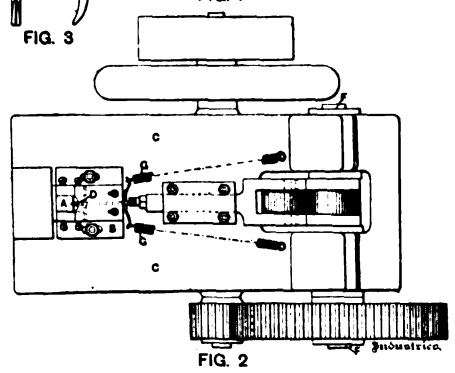

FIG. 3

FIG. 2

G (Fig. 2). The operation is as follows:—The cotter is formed with a straight shank, and is then placed in the groove in A; the slide D then advances, so holding the cotter in place. The slide E is then forced forward, so lengthening, bending, and bevelling the end of the cotter at one operation. Two claims are made, embracing the machine as described, with several modifications. —No. 4632. March 25th, 1890. 11*d*.

Gas Engines.—*J. P. Binns, Halifax.*—The inventor's object is to dispense with the use of inlet valves now employed for the introduction of the explosive mixture into the ignition chamber. To this end two cylinders are used, arranged side by side, one being of a much smaller diameter than the other. Through a port in or about the centre of the smaller cylinder the explosive mixture is supplied from the ordinary pump cylinder operated in the usual way. A similar port is formed in about the centre of the larger cylinder for the escape of the waste gases. One end of both the cylinders is in communication with the ignition chamber, and, as the pistons of both cylinders advance at the same time, both ports are closed simultaneously, and as the said pistons continue to advance, the explosive mixture is compressed within the common ignition chamber. After having reached the extent of their forward stroke, the pistons are forced back by the explosion of the combustible mixture, and the ports simultaneously opened. Another part of the invention consists in providing more efficient means of igniting the explosive charge at the proper time. To effect this the inventor forms a small passage leading out of the igniting chamber, and also a second small passage leading out of the larger cylinder on the opposite side to that to which the smaller cylinder is attached, which two passages are connected together by a tube maintained in a state of incandescence. A chamber is formed in the piston of the larger cylinder, from which a port in the side of the piston communicates with the exterior thereof. This port, when the piston is at the end of its forward stroke, comes opposite the port in the cylinder leading to the incandescent tube, so that the products of the previous combustion is forced, by the compressed gases, through the incandescent tube into the chamber in the larger piston when the said ports are opposite. Claims: (1) In gas engines, the use of an additional cylinder and piston, and an outlet port in combination with the explosive chamber arranged and operated as described; (2) the arrangement of ports or passages for forming a communication through the ignition tube in combination with said ports and a chamber in the larger piston for conveying away the spent gases as described.—No. 4362. March 20th, 1890. 8*d*.

Precipitators.—*C. A. MacDonald, Chicago, Illinois, U.S.A.*—The invention relates to an apparatus for precipitating oil and other impurities from exhaust steam. This apparatus consists of a cylindrical vessel with holes formed centrally in the end coverings. Passing up through the lower hole is the supply pipe, around the upper end of which is fixed a perforated diaphragm. Fixed to the outer edges of this diaphragm is a second and smaller cylinder, the upper end of which is closed. Fixed to the interior of the lower end of the inner cylinder is one edge of an annular perforated diaphragm, the other edge of which is connected to the bottom of the outer cylindrical casing in close proximity with the exterior of the supply pipe. Two other perforated annular diaphragms are connected at one edge to the upper and lower parts of the exterior of the inner cylinder and at their other edges respectively to the upper and lower ends of the outer casing. All these diaphragms, which are perforated, are so connected that they occupy a diagonal position. The exhaust steam on entering strikes the top of the inner cylindrical casing, and is so diverted as to travel downwards, and, passing through the first two diaphragms, it there strikes the bottom of the outer casing and is then caused to travel upwards through the last two diaphragms and escapes through the opening in the top of the outer casing. Three claims are made.—No. 18739. November 19th, 1890. 6*d*.

File Cutting Machines.—*J. Erlenwein, Edenkoben, Rhenish Bararia.*—In the accompanying illustratrations Fig. 1 is a side elevation, and Fig. 2 a front elevation of a machine constructed according to this invention. The operating hammer A, carried on a suitable spindle running in slide-ways in the upper part of

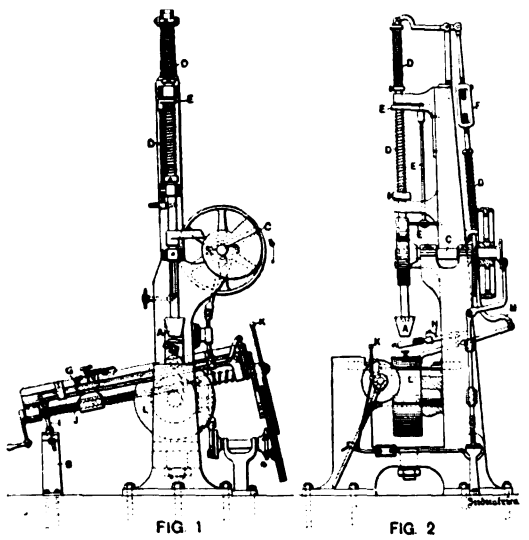

FIG. 1

FIG. 2

the frame work B, is raised by means of the cam on the main driving shaft C, and when released is forced quickly downwards by means of springs D, which had previously been compressed by its upward motion, the tension of said springs being made adjustable by means of arrangements E and F. The file is carried by means of a slide G in a frame H, the position of which may be altered by means of a screw I actuated by a screw J operated by suitably-arranged intermediate gearing from C, the gearing being so arranged that by raising or lowering the rod K, the travel, and so the pitch of the serration of the file may be increased or diminished. The screw J is divided into two parts, which may be connected or disconnected by a suitable frictional appliance, so that the gearing connecting it to C may be disengaged when desired to move the slide by hand. The file is moved over a stationary block L, having a zinc surface, by the slide G, and is held on said block by a lever M operated from

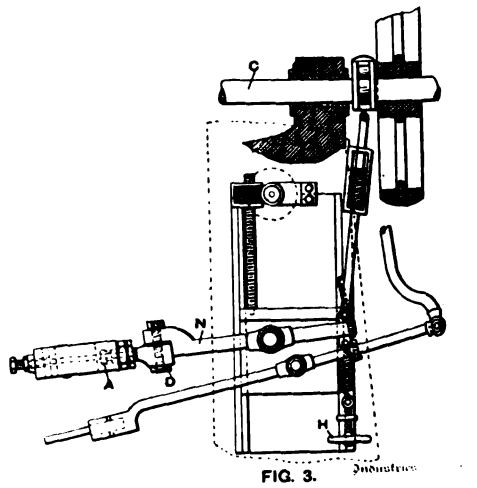

FIG. 3.

C. A second lever N, operated from C, as shown in the enlarged detail (Fig. 3), carries the chisel for cutting the file, and which is operated upon by the hammer H, and after being so operated upon is raised by the mechanism shown to clear it of the file. Three claims are made.—No. 13106. August 20th, 1890. 11*d*.

Steam Boiler Attachment.—*H. J. Haddan, London.* (*F. J. Haut, Floreffe, Belgium.*)—The invention relates to an attachment whereby the rise or fall of water in steam boilers above or below the normal level causes an alarm to be sounded. A suitable casing inside the boiler is screwed into the lower part of a steam whistle situated outside the boiler of the ordinary construction. The rod of the valve of said whistle passes down through the casing, and is normally forced upwards so as to keep the valve of the whistle on its seating by the combined action of the steam pressure and of a helical spring held between a suitable projection on the said spindle and the lower end of the casing. The valve spindle is provided in its lower part with a cross-bar, with a roller at each end. Above this cross-bar is pivoted to the casing a rod, to the longer end of which is fixed a float, which floats on the surface of the water. It will thus be seen that should the float rise or fall beyond a limited distance one part of the pivoted lever will strike one of the rollers on the cross-bar of

Digitized by Google

the valve spindle, so forcing the latter down and opening the valve of the whistle, so giving an alarm. Claim: The boiler attachment substantially as described.—No. 3088. February 26th, 1890. 6*d*.

Glass Bottle Machinery.—*D. Rylands, Shepcote, near Barnsley, & B. Stoner, Stairford, Barnsley, Yorkshire.*—In the annexed illustrations is shown an apparatus for the above purpose, Fig. 1 being a side elevation, Fig. 2 a front elevation, and Fig. 3 a sectional plan thereof. The pillar and stand A carries fixed and movable discs B B¹, in the latter of which are carried suitable shafts; on the inner ends of these are carried the friction wheels

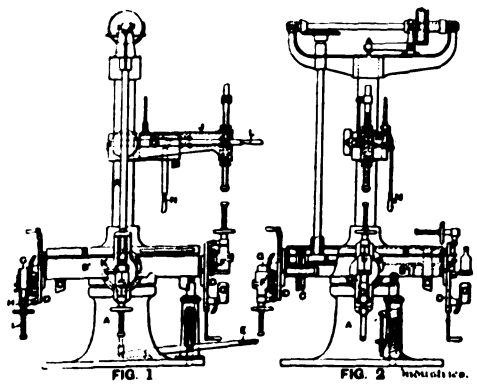

FIG. 1 FIG. 2

C in contact with the under surface of B, and on the outer end of which is the plate D carrying the dies. The disc B¹ is revolved as shown, the motion thereof being governed from a treadle E. The dies consist of the hinged body parts F, core G, and stopper H of a screwed or other suitable form, through which works the plunger I. The body F, reversed as shown to the left (Figs. 1 and 2), and with the stopper H and cone G inserted, is filled with glass and the disc B¹ then revolved, so reversing the position of the dies, bringing them under the pressing or blowing point J. The plunger I is then forced through H by means of the hand lever L. The core G is then removed, and a table K takes the place thereof. After I has been withdrawn a current of air from a reservoir M, the valves of which are operated by lever N, is then passed through or down the sides of the plug H and plunger I, and the bottle blown to the full size and shape. The plug H is then removed and the die opened, leaving the bottle in a finished condition. Claims: (1) In a machine for the manufacture of glass bottles or other glassware, the combination of a fixed or revolving table, having on the outer edge one or more brackets or plates carrying an outer and inner mould, and capable of being reversed in the manner described; (2) the combination with a bottle-making machine where the moulds are worked in a vertical position, of a special mechanical device or arrangement for the purpose of forming the bottle mouths with internal screw threads, with annular groove or grooves, with inclines, or of taper shape in the inside; (3) in combination with a bottle-making machine the use of an intermediate air-vessel having taps and levers substantially as shown and described for the purpose of blowing the bottles more equally and shapely; (4) a bottle-making machine having a screw-shaped split movable plug which is fixed in the mouth end of bottle-blowing mould

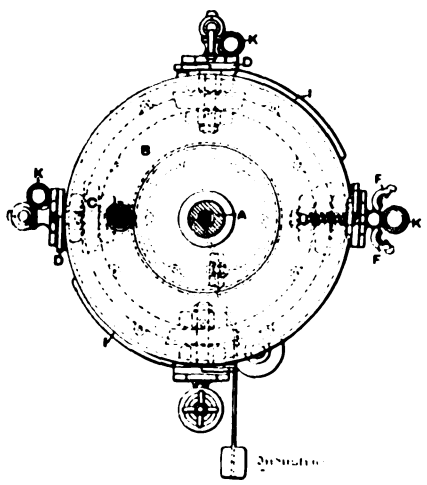

FIG. 3.

before the molten glass is poured into the pressing or inner mould, such plug being capable of forming any special internal shape or configuration of bottle-mouth, while the moulds are either in an inverted or in an upright position, the said plug being secured to mould, and operated by any suitable mechanical means.—No. 4599. March 22nd, 1890. 8*d*.

Apparatus for Lowering Ships' Boats.—*W. McGlashan & J. P. Rawlings, both of Leith, Midlothian, N.B.*—The apparatus for the above purpose is constructed as follows:—Supported in two suitable brackets fixed to the ship is a horizontal shaft, in the centre of which is keyed a worm-wheel actuated by means of a worm, the shaft of which is supported in a third bracket. Fixed to each end of said horizontal shaft is a radial arm, the outer end of which is connected by a link of suitable length to a projection on the davit, the lower end of which is pivoted to the end bracket, but at some distance in front of and slightly above the bearing of the horizontal shaft. The davits are of an L-shape, with the upper end of the vertical arm, however, inclined somewhat to the horizontal arm. The parts are so arranged that, by revolving the horizontal shaft, the davits will be moved forward around their pivots, so carrying the boat forward and lowering it at the same time. Four claims are made.—No. 5578. April 12th, 1890. 6*d*.

Spinning Machinery.—*J. Longmore & W. L. Watson, both of London.*—Instead of using a stationary ring for effecting the opening and twisting, the inventors use one that is positively rotated, and in which the fibres are carried in a circular path by passing through a hole or equivalent yarn-guide formed eccentrically on the ring. The bobbin on which the yarn is wound is driven merely by the tension on the yarn between the ring and bobbin or may be driven positively if desired. To enable the yarn to be evenly wound on the bobbin, the latter is reciprocated through the central opening of the ring. The ring is grooved at its periphery, in which groove and a corresponding groove in the interior of the bearing are held a suitable number of metal balls. Claims: (1) Spinning or twisting fibres by means of a revolving ring which carries the yarn in a circular path and winds it on a bobbin which is longitudinally reciprocated through the central opening of the ring; (2) a ring mounted as described and having an eccentric yarn carrier and a driving pulley; (3) a revolvable ring provided with a yarn carrier, the circular path travelled by which is of less diameter than that of the bearing within which the ring rotates and less than the diameter of the driving pulley; (4) the arrangement of a ball bearing of the ring as described.—No. 5709. April 15th, 1890. 8*d*.

Grinding Machines.—*J. G. Freeman, Frindsbury, Strood, Kent.*—The invention relates to the construction of grinding machines wherein the rolls are pressed upon their race by hydraulic pressure. A machine of this description is shown in sectional elevation at Fig. 1, and sectional plan at Fig. 2, of the annexed illustrations. The spindles A of the rolls B run in suitable bearings in the casing C, the inner set of bearings being formed in the central boss D, held in the opening E, through which the material to be crushed is fed, by suitable webbing. The boss D also receives the end of the driving shaft F and the piston rod G of the hydraulic cylinder H, formed in a cross-piece I. The pressure of the rolls upon the race J is thus

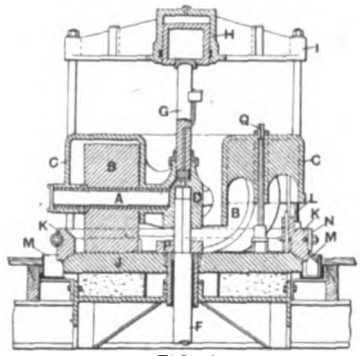

FIG. 1

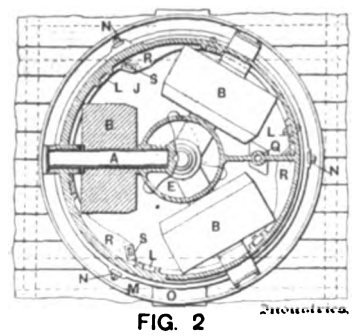

FIG. 2

augmented from the cylinder H. The edge of J and the underside of the curb K, attached to the frame C by slings L, are bevelled as shown, and have let into their bevelled edges strips of soft metal, which, wearing more rapidly than the said edges, which are made of hard steel, form ridges, which pulverise the material as it passes through them to the annular trough M, from which it is swept by plates N into the opening O. The material to be crushed is fed through E and distributed over J by disperser P, fixed to the driving spindle. The further progress of the material towards the periphery of J is governed by plough Q, carried in C, and formed of diamond-shaped plates set horizontally, and having formed on two opposite edges vertical deflecting plates. That material which is not sufficiently crushed when it reaches the periphery of J is swept back under the rolls by means of plates R fixed to K, the other material being carried between the edge of J and K by scrapers S carried in R. Five claims are made.—No. 5950. April 19th, 1890. 8*d*.

Slide-gate Valves.—*H. H. Lake, London. (The Ross Valve Company, New York, U.S.A.)*—The valve casing is of the ordinary construction, having a socket in its upper part in which a collar on the gate spindle is allowed to revolve, but is prevented from moving longitudinally therein. Screwed on to the lower end of the actuating spindle is the gate carrier which has trunnions on each side of it, on which the gates are held by said trunnions fitting loosely into sockets in the back thereof. Formed at each side of the carrier block are two slots, the open sides of which face the back of the gates. The upper ends of these slots are wedge shaped, so that balls pressed on the face thereof will be forced outwards. One arm of a bifurcated plunger is adapted to slide in said slots, the ends of said arms being also of a wedge shape. Between the ends of the slots and the heads or the arms of the plunger are first two metal balls placed side by side, then a roller, and again two metal balls placed side by side. It will thus be seen that as the carrier is forced downwards the lower end of the plunger in striking against the lower parts of the valve casing will force the two pairs of balls from one another against the backs of the gates, so pressing the latter against their seatings. Claims: (1) In a slide-gate valve the combination with an enclosing case of a slide-gate, a gate carrier having bearing-block-engaging abutment, and a carrier stem projecting exteriorly of the case of a seating plunger, a nest of bearing blocks interposed between such gate and a resisting medium comprising two pairs of bearing blocks, one pair bearing upon the gate and the other pair upon the resisting medium, and a mobile block interposed between the pairs; (2) in combination with the parts above mentioned a seating plunger provided with a laterally yielding foot.—No. 20108. December 9th, 1890. 8*d*.

Platen Printing Machines.—*W. Mackenzie, Chorlton-on-Medlock, Manchester.*—The invention relates to improvements in platen printing machines whereby it is possible to print in two colours in exact register upon the same printing sheet. The machine for this purpose is shown in the annexed illustrations, of which Fig. 1 is a front elevation (with the inking rollers and

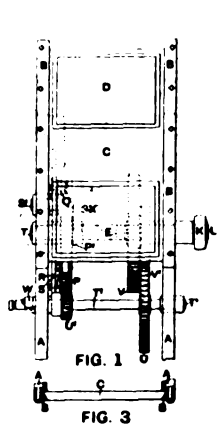

FIG. 1

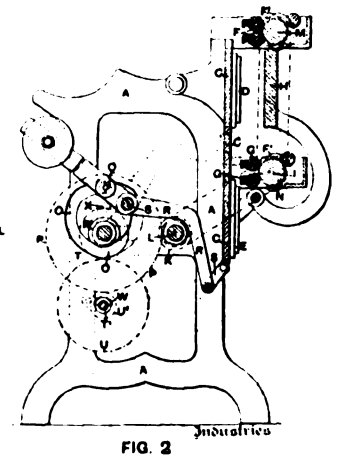

FIG. 2

FIG. 3

platen removed), Fig. 2 a side sectional elevation, and Fig. 3 a detail horizontal section. Sliding in grooves in the front of the framework A is the plate C carrying two chases of type D E. Two sets of inking rollers F and G are arranged to ink their respective printing surfaces, and are driven by frictional rollers M N and belts from the shaft L. These inking rollers are pressed slightly forward at suitable intervals so as to come in contact with the type by means of cams F¹ F². A single platen common to both printing surfaces is used, on which the paper to be printed is placed. The slide C is given a reciprocating motion, with two pauses, so as to allow of the impressions being taken by means of the weighted lever R pivoted at S, one end of which is connected by a link to C, and the other end carrying a friction bowl Q adapted to run in a cam groove O, formed, as shown, in the surface of a gear wheel P driven from the shaft P¹. Claims: (1) The construction of platen printing machines for printing in two distinct colours, or printing two impressions alternately in the same colours, as described; (2) the improved printing machine provided with a movable table carrying two chases and actuated by a cam groove and lever arrangement mounted and operating as described; (3) in the improved platen printing machine the employment of two sets of inking rollers and corresponding sets of type as described.—No. 8978. March 13th, 1890. 8*d*.

Evaporator.—*R. Harvey, Glasgow, N.B.*—The apparatus for the above purpose is shown in the annexed illustrations, of which Fig. 1 is a vertical sectional elevation and Fig. 2 a transverse section. The circular casing A has fixed in its lower part the two tube plates B, carrying between them the set of smaller tubes C and the large tube C¹, all forming a communication between the upper and lower parts of A. The steam, or hot gases, are supplied through the branch pipes D, the supply being governed by means of suitable sluice valves E, and circulate amongst the tubes C through perforations in the central deflecting plate F, and escape with the water of condensation through D¹. The liquid to be evaporated is supplied at G (shown in dotted lines) and passes down the tube C¹, striking the bottom of A, and travelling upwards through C, but is again carried downwards through C¹ by means of the current caused by the liquid

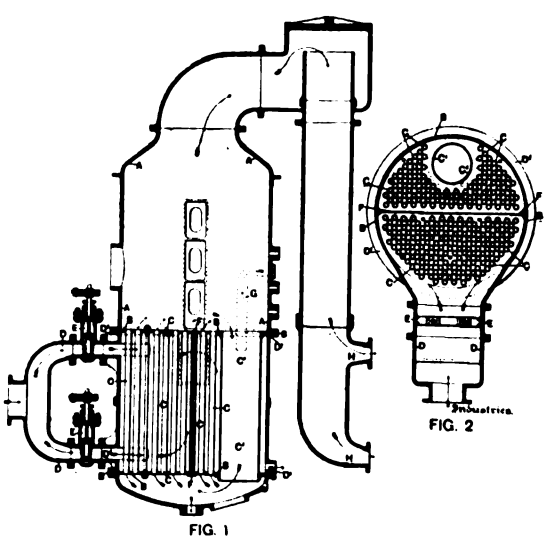

FIG. 2

FIG. 1

supplied from G. The vapour evaporated from the liquid escapes upwards as shown by the arrows, and escapes through openings H. If desired, several evaporating apparatus can be used together, being connected in series. The inventor claims: (1) The construction and use of single or multiple effect evaporating vessels for sugar juice and other liquors with duplex expanding branches which lead the steam or vapour from a single branch to the upper and lower parts, and to the full size of the tubular heating vessel or vessels; (2) the construction and use of duplex expanding steam or vapour inlet branches in the tubular heating

Digitized by Google

vessel, in combination with one or more intercepting vapour vertical deflecting plates within the tubular vessel; (3) the fitting and use of sluice or other valves on both the upper and lower branches of the heating vessel as described.—No. 3907. March 12th, 1890. 8*d.*

UNIVERSAL JOINT.—*F. Y. Wolseley, London, & P. P. Craven, Forest Gate, Essex.*—A short cylindrical tube of a suitable diameter has formed internally at one end one part of a hollow spherical bearing to receive a ball fixed to one end of one of the shafts to be connected. The other end of this tube is screw-threaded, and receives a plug, the inner end of which is hollowed out to form the other part of the spherical bearing. One end of the second shaft of the pair to be connected is connected to this plug. The ball or sphere which fits into the spherical bearing has formed around it, preferably in the same plane as the rod connected to it, an annular groove, into which groove project the ends of two set screws screwed into and through the cylindrical tube at diametrically opposite points. Four claims are made, embracing the universal joint, constructed substantially as described, with modifications.—No. 3956. March 13th, 1890. 8*d.*

WOOD WORKING MACHINERY.—*T. N. Robinson, Rochdale.*—The invention relates to those wood-planing and moulding machines in which stationary knives are employed either with or without revolving cutters. An apparatus embraced by this invention is shown in the annexed illustrations, Fig. 1 being a side elevation and Fig. 2 a plan thereof. A fixed vertical frame A is secured to the machine bed B behind the knives C; in slideways on this bracket A is mounted an adjustable carriage D for carrying the pressure rollers. This carriage is arranged so that it can be raised and lowered by a hand-wheel E actuating a screw F in the fixed frame A, and it is further capable of a short transverse movement for adjusting its position laterally by means of two adjusting screws G working in lugs H on the bracket A. The adjustable carriage D consists of an open framework with suitable recesses to receive and carry a number of open bridles I, in each of which are mounted a pair of pressure rollers J when two knives are used. The recesses in the adjustable carriage D allow the pressure rollers J to be placed at suitable distances apart for holding down varying widths of boards, and when necessary, one, two, or more of the bridles I and rollers J can be removed from the carriage D. Pressure is given to the pressure rollers by means of weighted levers K pivoted to frame D carrying a link L, the lower end of which presses on the bridle I. The levers K may be raised to relieve the pressure rollers by means of an eccentric rod M pivoted in D. Claims: (1) The combination with a wood planing and moulding machine of the improved pressure apparatus

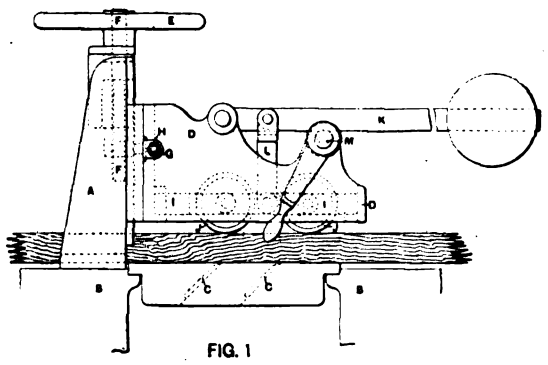

FIG. 1

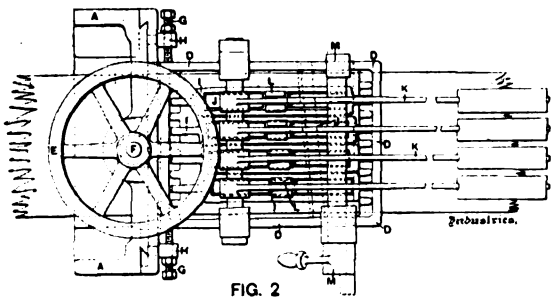

FIG. 2

consisting essentially of an adjustable carriage or open framework in which are mounted any suitable number of pressure rollers weighted by fulcrumed weighted bars or equivalent means. (2) The combination of the bracket A, the adjustable carriage D, bridles I, pressure rollers J, fulcrumed weight bars K, and eccentric shaft M, all for the purposes described.—No. 5899. April 18th, 1890. 6*d.*

GAS RETORTS AND CHARGING APPARATUS THEREFOR.—*C. Hunt, Birmingham.*—The inventor's object is to prevent the tendency on the part of inclined retorts to slide upon their bearings, and so endanger their structure, and to charge said retorts with facility. To effect the first object the inventor moulds on either or both the upper and lower surfaces of the retorts snugs so shaped and placed that those on the underside of the retort take a vertical bearing upon the supporting walls, so converting a side into a vertical thrust, while upon the upper snugs the cross walls may be supported. The charging apparatus is constructed as follows;—Upon a suitable horizontal carriage arranged to run on a tramway laid longitudinally in front of the retort benches is carried a second carriage rectangular in front elevation and plan, but of a right-angled triangular form in side elevation, the vertical side being next to the retort benches. This framework or carriage is also mounted on wheels, and runs on short transverse rails on the horizontal carriage. Between the uprights of this framework a triangular or other shaped hopper is suspended by chains passing over pulleys at the top of the framework, and operated by means of a suitable winch. The hopper can thus be raised or lowered or moved horizontally so as to allow it to be brought into position, and its end, which is suitably shaped to fit the ends of the retorts, inserted in the latter. The lower end of the shoot is also provided with a door, which can be opened or closed by means of a suitable lever by the attendant, by means of which the contents of the hopper may be allowed to pass into the retort. The hopper receives its coal from a trough or continuous hopper furnished with shoots at convenient intervals, and running through the retort-house. Claims: (1) The construction and application of inclined gas retorts with snugs on their outer surfaces as described; (2) the construction and application of movable apparatus in combination with inclined gas retorts for charging the said retorts as described.—No. 5078. April 1st, 1890. 8*d.*

ELECTRICITY.

TELEGRAPHIC RECEIVING APPARATUS.—*P. B. Delany, South Orange, New Jersey State, U.S.A.*—The receiving apparatus as constructed according to the present invention is shown in plan and part sectional elevation at Figs. 1 and 2 respectively of the annexed illustrations. A magnet A, supported on a base B, as

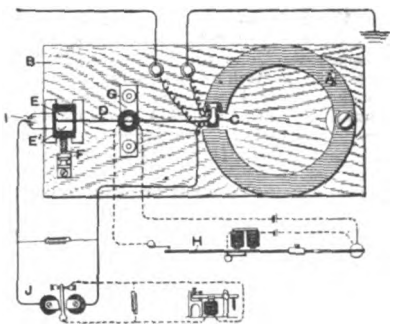

FIG. 1.

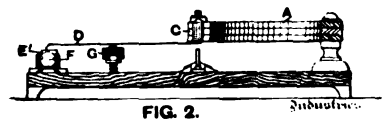

FIG. 2.

shown, has pivoted between the poles a coil C, fixed to which is an aluminium arm D. The point of this arm is bent and tipped with platinum, and is arranged, normally, to oscillate in a vertical direction between the two plates E E¹, made adjustable to or from one another by means of an insulated screw F. The oscillation of D in the vertical plane is caused by an electromagnet G, placed beneath it intermediately between coil C and plates E E¹, the circuit around which is interrupted by an automatic vibrator H (Fig. 1). The contact plates E E¹ are connected to the poles of a local split battery I, the middle of which is connected to D through a polarised relay J, controlling a local circuit in which is placed a sounder of ordinary construction. The contacts of the polarised relay and contacts E E¹ are shunted by condensers as usual. The line wire is connected in series with the winding on C. If the distant operator closes his key and quickly opens it a positive and then a negative current will be sent into the cable and through the trailer of the transmitter, so causing the pointer D to first swing to the right and then to the left, so first closing and then opening the sounder circuit. If sending a dash the key is held down, so that there is no reverse or negative impulse. Seven claims are made.—No. 3839. March 11th, 1890. 8*d.*

DYNAMOS AND MOTORS.—*J. Radcliffe, East Retford, Nottinghamshire.*—The invention embraces means for automatically (1) changing the angular position of the segments of the commutator to enable the machine to run in either direction without altering the position of the brushes and (2) adjusting the lead to suit all speeds, (3) and an arrangement in combination with the above for cutting a resistance in any part of the circuit for regulating the strength of the current. To accomplish these ends, the commutator is fixed to the hub of the driving pulley, the said hub being free to move within certain limits in a circular direction on a second hub or sleeve, the latter being also free to move within certain limits on the armature shaft, the amount of motion in each case being limited by projections on the armature shaft and second hub respectively engaging in slots in the second and first hubs. One of these slots is a segmental one, but the second is a double helical slot, so that as the hub wherein it is formed revolves independently said hub will be moved longitudinally, which movement actuates a suitable lever of a regulating switch. Between the outer and inner hubs a pair of differential springs are arranged so as to be equally balanced when the projection on the inner hub is in the centre of the segmental slot in the outer hub. Three claims are made, embracing the arrangements as described.—No. 5836. April 17th, 1890. 8*d.*

ELECTRICAL RAILWAY SIGNALS.—*A. Siemens, London.*—The invention embraces an apparatus which may be combined with the apparatus described in a prior patent, No. 15921 of 1888, in such a manner that two or more signals require to be brought into "danger" position before another signal can be brought into "line clear" position. The apparatus for this purpose is constructed as follows:—Pivoted to an axis held in the upper end of a suitable support fixed to a base of insulating material is a rod carrying on its upper end a semicircular core formed of a bar of soft iron, the ends of which project into the interior of two solenoids fixed at opposite sides of the base. On the axis is fixed a rotary switch or commutator, against which bear two springs. The action is as follows:—When one of the solenoids is excited by a current passing through its coil, one end of the core is attracted, and as in the movement its centre of gravity passes the vertical line of its axis, it remains in the position to which it is attracted after the solenoid ceases to be excited. But when the other solenoid is excited, the other end of the bar is attracted and tumbles to the other side and there remains. In the first-named position of the core it effects the closing of a local circuit which starts from a contact made by a train when this is about to enter the section protected by the signal; thence passes through certain other conflicting signals, provided they are in the danger position, in which they make the requisite contacts; then through the second solenoid and into the above-mentioned signal, effecting the lowering of the same to "line clear." The winding of the solenoids of this special apparatus is arranged in connection with the circular switch and springs pressing thereon in such a manner that when the core tumbles in one direction the current of the solenoid which attracted it is opened. Claim: The auxiliary signal apparatus as described.—No. 4242. March 18th, 1890. 8*d.*

CHEMISTRY.

EXPLOSIVES.—*H. H. Lake, London.* (*S. H. Emmens, Emmens, Westmoreland, Pennsylvania, U.S.A.*).—The invention relates to explosives of the gun-cotton class. In a bath of mixed sulphuric and nitric acids of a strength ordinarily employed for the manufacture of gun-cotton, unsized paper is steeped for about two minutes. The paper is then removed from the acid and washed one or more times, after which it is immersed in a cold aqueous solution of carbonate of ammonia, and kept therein until all effervescence ceases. It is then removed to another bath containing a strong solution of picric acid heated to 100° C. or thereabouts. The paper, after remaining in the vessel about ten minutes, is then suspended in another vessel containing ammoniacal water until the adhering picric acid is converted into picrate of ammonia; it is then dried, and is ready for use as an explosive. Claim: An explosive substance consisting of paper, or paper-stock, converted into a nitro-compound, and impregnated with ammonia and picric acid substantially as described.—No. 3852. March 11th, 1890. 4*d.*

CLEANING COTTON.—*J. Saleha, Beckenham, Kent.*—The invention embraces a method of cleaning and separating cotton from cotton seeds. For this purpose the inventor either uses an acid or basic treatment. In the first case the cotton seeds are subjected to the action of a solution of hydrochloric acid or nitric acid, or a mixture of both; and, in the second case, the seeds are subjected to the action of a solution of caustic soda or caustic potash, or a mixture of both. The seeds are subsequently dried, and the cotton may then be easily brushed off. The quantity of water added as a solvent of the above acids or bases is about 10 per cent. or thereabouts. The seeds are placed in an air-tight chamber, together with the acid or alkaline solution, and heated, the steam or vapour given off being allowed to pass to a suitable condenser. Claims: (1) The method of separating cotton from cotton seeds by means of a solution of hydrochloric or nitric acid, or a mixture of both, as described; (2) the method of separating cotton from cotton seed by means of a solution of a caustic alkaline base; (3) in the process of separating cotton from cotton seeds the use of a heated chamber connected with a condenser as described.—No. 5271. April 5th, 1890. 4*d.*

MISCELLANEOUS.

EXTRACTION OF TIN FROM TIN SLAG.—*T. Teague, Pinewood, Devoran, Cornwall.*—According to this invention, tin slag in fragments is charged into pots, together with suitable fluxes, preferably in fragments, and in cases where there is little or no reducing material in the slag, coal dust or other pulverulent carbonaceous matter is used. The fluxes for the above purpose are fluor or other spars, Elvan blue, or mixtures of these from 10–25 per cent. of the weight of the slag. The slag fluxes and reducing material are well mixed in the pot, and are melted in any suitable furnace. The molten material is then poured into a mould of a coned shape of iron or sand and, after cooling, the tin collects in a button at the bottom. Claims: The hereindescribed process for extraction of tin from slag or refuse of tin smelting, by melting the slag mixed with suitable fluxes and casting the molten mass in moulds suitable for subsidence of the tin.—No. 5638. April 14th, 1890. 4*d.*

TREATMENT OF COPPER-NICKEL MATTE.—*The Electric Construction Corporation, Limited, London, & S. Parker & A. E. Robinson, both of Wolverhampton.*—The object of this invention is to improve and cheapen the treatment of copper-nickel matte in such a manner as to obtain the metals without the roasting process. The matte is treated directly with dilute sulphuric acid, preferably after being previously pulverised. By this means the nickel and iron are dissolved, but the principal part of the copper remains undissolved. The residue (consisting of metallic copper and sulphide of copper) can be melted and cast into pigs, and may be used at the anodes in an electrolyte of sulphate of copper with a copper cathode. The solution containing the iron and nickel is treated with a precipitant such as carbonate of barium to precipitate the iron. Claims: In the treatment of copper-nickel matte the use of dilute sulphuric acid as a solvent for the nickel and iron as described.—No. 5199. April 3rd, 1890. 4*d.*

MANUFACTURE OF BAR IRON.—*W. P. Hopkins, Catasauqua, Pennsylvania, U.S.A.*—In the manufacture of bar iron, instead of first rolling the scrap or puddle-ball after leaving the squeezer into flat scrap bars, then cutting the said bars into shorter bars, then piling, reheating, and rolling into the desired shape, the inventor proceeds as follows:—The puddle-ball is rolled directly into channel iron, and these channels are piled upon one another to a suitable height to suit the size of bar to be made, each channel iron being filled with waste scrap iron. The pile thus formed is then reheated and rolled to the desired shape. Claims: (1) The method of manufacturing bar iron as described; (2) the pile as described.—No. 19572. December 1st, 1890. 6d.

Copies of the British specifications may be obtained on application to H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE NICARAGUA CANAL.

I.

HISTORICAL SKETCH.

In 1513 Vasco Nuñez de Balboa discovered the Pacific Ocean, and the fact that only a comparatively narrow isthmus separated this ocean from its neighbour—the Atlantic—was established. Even before this date, however, as early as 1502, the great Columbus himself had explored the entire coast from Cape Gracias á Dios, the north-easterly point of Nicaragua, to the Isthmus of Panama, in search of a passage by which he hoped to reach Zipangu and the kingdom of the Great Khan, supposed to be the sources of fabulous wealth. For many years after the discovery of the Pacific Ocean it was hoped and expected that a natural waterway across the isthmus would be found, and the search for this strait was diligently prosecuted by various adventurers, including Cortez and the Cabots.

In Spain, engineers at Madrid proposed, as far back as 1528, the establishment of water communication between the Atlantic and Pacific Oceans by way of the River Chagres. Antonio Galvao, a Portuguese navigator, in 1550 published a memoir in which four different routes for a passage across the isthmus were suggested, including those by Lake Nicaragua, and by the Isthmus of Panama.

According to José de Aosta, the historian, in 1590 the project for cutting a canal to unite the two oceans appears still to have been contemplated, but was subsequent to this date opposed rather than promoted, by Spain, from motives of national jealousy, inspired by the desire to maintain a monopoly of her South American trade.

Up to 1771 the scheme appears to have been practically forgotten, but at that date, by the order of Antonio Bucareli, Viceroy of Mexico, a survey was undertaken by the engineers, Antonio Cramer and Miguel del Corral, in order to ascertain whether it would be feasible to cut a canal joining the rivers Chimalapa and Huascualco. The report made by them advocated the construction of a canal of small dimensions. This report was of sufficient value to be afterwards utilised by Baron Humboldt in making his map of the isthmus. In a further report in 1779, by Cramer, Ysasi, and Muestro, on the Nicaragua route, the latter was stated to be impracticable.

During the war between England and Spain, which broke out in 1779, Fort St. Juan was captured by the English, with a view to obtaining possession of the Desaguadero and Lake Nicaragua and the cities of Granada and Leon, cutting in two the Spanish possessions in Central America, and securing the route for an interoceanic canal. Owing to the severe sufferings of the troops, in consequence of the climate, the expedition was eventually abandoned.

Baron Alexander von Humboldt discusses the practicability of a waterway connecting the Atlantic and Pacific Oceans in his "Personal Narrative of Travels" (Vol. VI., pp. 239 to 300), and the following quotation from his writings on this subject is of interest:—"The Isthmus of Nicaragua and that of Cupica have always appeared to me the most favourable for the formation of canals of large dimensions, similar to the Caledonian Canal, which is 103ft. (French measure) broad at the water's edge, exclusive of the raised way which stops the falling in of the earth; 47ft. broad at the bottom, and 18½ft. deep. In considering a communication between two seas, capable of producing a reduction in the commercial world, we must not limit our attention to such means as only serve to establish a system of inland navigation by small locks, as in the canals of Languedoc, Briare, or in the Grand Junction, and the Forth and Clyde Canals." Humboldt, it must be remembered, had spent ten years, from 1798, in exploring the Spanish-American States and the isthmus, and therefore spoke with a thorough knowledge of his subject.

From 1824 to 1839 several surveys of various parts of the isthmus were made on behalf of the Central American States, and a concession was granted, in 1838, by the Government of New Granada to Solomon & Co., a French firm, for the construction of either canals, roads, or railroads across the isthmus. In the latter scheme the French Government took so much interest that M. Guizot, the Prime Minister under Louis Philippe, commissioned M. Garella to make a survey.

The Government of the United States first began to take a serious interest in the question of an interoceanic canal through Central America in the year 1825, and this interest has been more or less continuously maintained ever since. It is worthy of notice that, from the very first, the American Government favoured the Nicaraguan route, the superiority of which over others proposed seems to have been considered established almost beyond doubt. A proposal was made to the United States Government by the new Republic of

THE NICARAGUA CANAL.

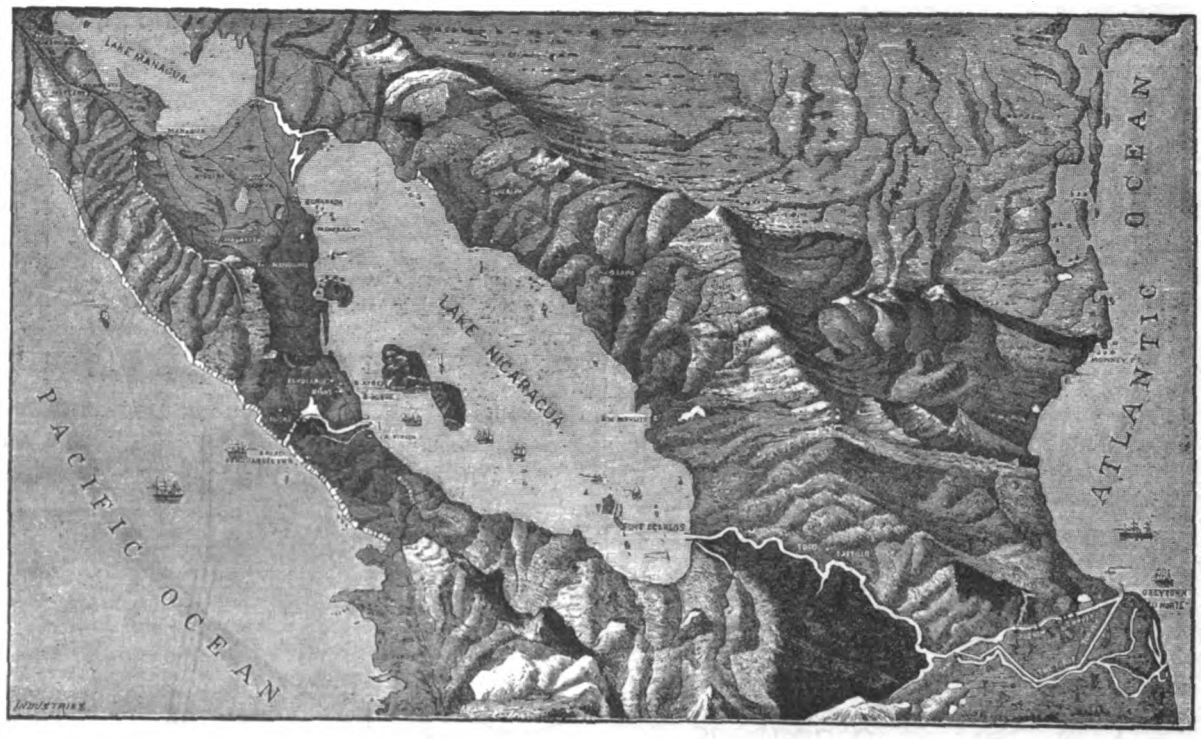

Fig. 1.—Bird's-eye View of Canal.

Central America, in 1825, to the effect that the former should co-operate with the latter to promote the opening of a canal through the province of Nicaragua to unite the Atlantic with the Pacific Ocean, and that the advantages resulting from the canal should be perpetually secured by treaty to the two nations. This proposal was favourably entertained by the President of the United States, John Quincy Adams, acting through the Secretary of State, the Hon. Henry Clay, and Mr. Williams, the then Chargé d'Affaires in Central America, was instructed to investigate the merits of the scheme, and obtain information as to the surveys already made, the facilities afforded by the country, and the state of its population, for making the canal, and the estimated cost. Soon afterwards a contract was entered into between the Central American Government and Mr. A. H. Palmer, of New York, for the construction of a canal through Nicaragua of sufficient capacity "for vessels of the largest burden possible." The undertaking proved abortive, owing to the inability of the promoters to raise the capital considered necessary, estimated at only $5,000,000, a sum which, in the light of recent knowledge, was obviously totally inadequate, and shows that the surveys and estimates must have been very imperfect. The evident merits of the project induced the King of the Netherlands to take up the matter on his own personal account, and also as patron of an association of capitalists. An envoy, General Ver Veer, was sent to Nicaragua to treat with the Central American Government in March, 1829, but, owing to political disturbances, action was delayed until 1830, when the construction of the canal was authorised, with the object of offering it to the association already formed for the purpose in the Netherlands. At this point the United States thought it time to put in a word, and the Chargé d'Affaires in Central America was instructed to claim for the United States their rights, under treaty terms, to whatever privileges were granted to others. The political revolution in the Netherlands, which terminated in the independence of Belgium, put an end to this enterprise also.

At short intervals, under various Presidents, the United States Government continued to manifest its interest in the canal question, by appointing special agents to report on the subject, passing resolutions, and concluding treaties with the Central American States. In a treaty with New Granada (now the United States of Columbia), ratified in 1848, the United States went so far as to guarantee the integrity of the territory of New Granada in return for participation in all the exemptions, privileges, and immunities concerning commerce and navigation "which are now or may hereafter be enjoyed by Granadian citizens," and for the right of way across the isthmus by any means of communication then existing or subsequently constructed.

In 1837 and 1838 an Englishman, Lieutenant John Bailey, of the Royal Marines, had, on behalf of the Central American Government, surveyed a proposed canal route, *viâ* Lake Nicaragua, and of the results of this survey one of the confidential agents, Mr. J. L. Stephens, sent out by the United States, was able to avail himself in framing his report. He characterised Lieutenant Bailey's results as "the most reliable data that have ever been published" on the subject. About the year 1848 the seizure of San Juan de Nicaragua, afterwards named Greytown, by the British Government, ostensibly for the protection of a savage ally, the King of the Mosquitos, caused considerable excitement in the United States, which were repeatedly requested by the Government of Nicaragua to interfere on its behalf. It was thought, probably not without reason, that the real purpose of this annexation by Great Britain was to obtain control of the prospective interoceanic canal. The negotiations which followed resulted in the conclusion of the Clayton-Bulwer Treaty, on April 19th, 1850, which eventually put an end to the Mosquito protectorate. A few months previous to this date a concession was granted by Nicaragua to the American Atlantic and Pacific Ship Canal Company, and a survey, to which we shall again have occasion to refer, was carried out by Colonel O. W. Childs, which tended to confirm the advantages of the Nicaraguan route as compared with others proposed. In a treaty of commerce and friendship negotiated at the same time between the United States and Nicaragua, it was stipulated that, "if by any contingency the above-named American Atlantic and Pacific Ship Canal Company shall fail to comply with the terms of their contract," then "all the rights and privileges which said contract confers shall accrue to any company of citizens of the United States which shall, within one year after the official declaration of failure, undertake to comply with its provisions."

We have given a somewhat full account of the transactions just recorded, chiefly with a view to showing the serious interest taken in the matter by the United States, as demonstrated by their very evident anxiety to have a hand in any prospective undertaking of the kind in question. Between 1850 and the outbreak of the great Civil War several surveys for interoceanic canal routes were undertaken, both as the result of private enterprise and at the instance of the United States Government, including explorations of the Isthmus of Darien, which ended in proving the latter unsuited for the purpose of a canal. After the war, which for many years put a stop to all engineering enterprise not immediately connected with it, General Grant interested himself in the subject of a ship canal through the isthmus, and during his presidency official surveys were undertaken of the various suggested routes, including the lines through Honduras, Tehuantepec, Nicaragua, Panama, Atrato, and Darien. On the Nicaraguan survey Mr. A. G. Menocal, the present chief engineer of the Nicaragua Canal Construction Company, was appointed chief engineer. When all the reports of the various surveying parties had been sent in, they were submitted, in 1876, to a commission appointed for the purpose by the President, which, after a careful study of the infor-

CARSON'S IMPROVED MARINE BOILER.

CONSTRUCTED BY EARLE'S SHIPBUILDING AND ENGINEERING COMPANY, LIMITED, HULL.

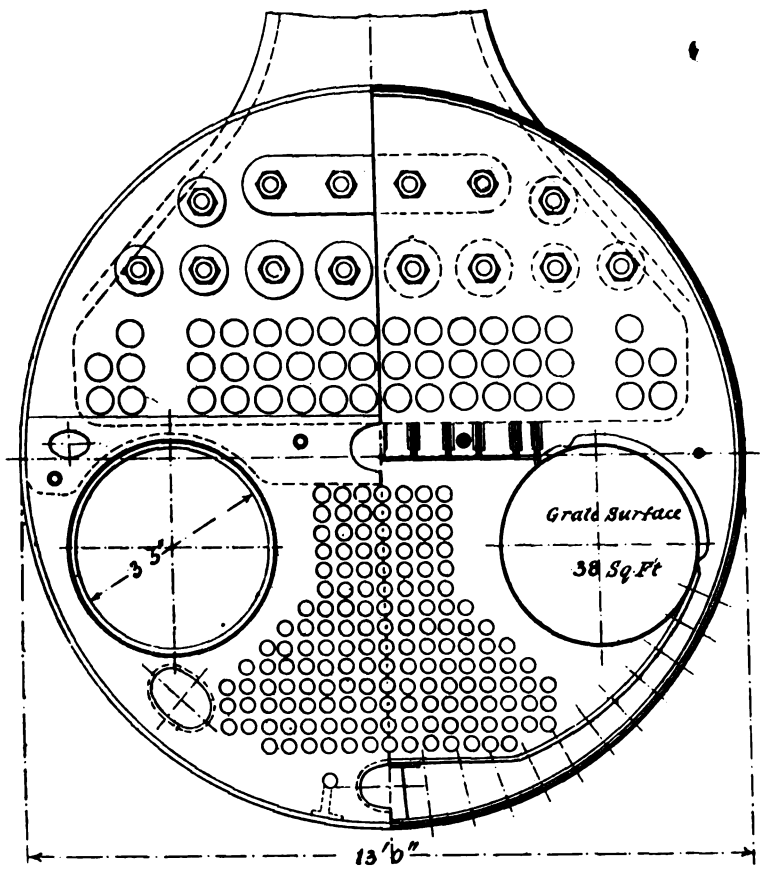

FIG. 1.—FRONT PART SECTIONAL ELEVATION.

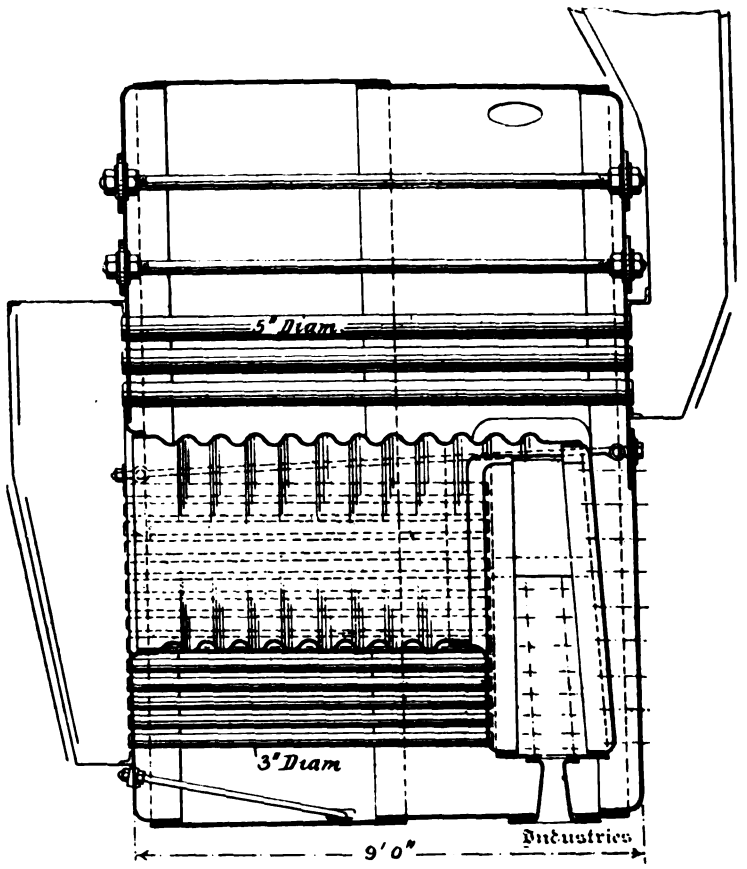

FIG. 2.—SIDE SECTIONAL ELEVATION.

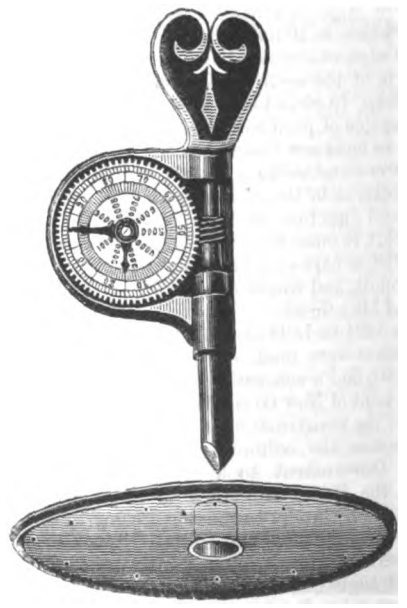
mation laid before them, unanimously reported in favour of the Nicaraguan route. After this the matter was again allowed to drop until the year 1879, when the news of the concession granted to Lieut. Wyse for the construction of the Panama Canal seems to have roused the United States to further action. In 1880 a concession was obtained from Nicaragua by the Provisional Interoceanic Canal Society, of which concession, owing to the delay caused by the opposition of M. de Lesseps and Captain Eads, a renewal eventually became necessary, and the Provisional Society was merged into the Maritime Canal Company of Nicaragua. During this period it appears that the Secretary of State, Mr. Frelinghuysen, was actively engaged in preparing the way for a treaty regarding the construction of the canal by the United States Government itself, and in December, 1884, the limit of time allowed to the Maritime Canal Company for commencing work having expired, Mr. Frelinghuysen's treaty was submitted to the Senate. The Senate, however, rejected the treaty, and it was withdrawn and not again presented to Congress.

Private enterprise once more returned to the charge, and after many delays and much opposition a Maritime Canal Company of Nicaragua was finally incorporated, on February 20th, 1889, under whose auspices the canal is now in course of construction. At an earlier period, when first formed, the association had taken care to inform themselves as to the attitude of the Government towards the enterprise, and elicited a statement from President Cleveland, in which he repudiated the proposed treaty with Nicaragua, already referred to, drawn up under his predecessor. In this statement the following passage occurs:—"I am unable to recommend propositions involving paramount privileges of ownership or right outside of our own territory, *when coupled with absolute and unlimited engagements to defend the territorial integrity of the States where such interests lie.* While the general project to connect the two oceans by means of a canal is to be encouraged, I am of the opinion that any scheme to that end, to be considered with favour, should be free from the features alluded to."

We have thus far dealt only with the historical aspect of our subject, which is of considerable interest and importance, more especially in so far as it indicates the attitude of the United States Government with regard to the construction of an interoceanic waterway. In our next article we shall proceed to consider in greater detail the merits of the Nicaragua route in connection with the results of recent surveys and explorations. Our illustration on page 300 (Fig. 2) shows, on a chart of the world, the relative distances which will be saved by the use of the proposed canal, while Fig. 1, on page 289, gives a bird's-eye view of the canal.

(To be continued.)



CARSON'S IMPROVED MARINE BOILER.

THERE is very little variety in the designs of modern marine boilers. From time to time new designs are proposed, but little or nothing is practically accomplished. Mr. R. Carson, Marine Superintendent, Hull, has, however, not only invented what appears to be a considerable improvement as regards multitubular boilers for marine and other purposes, but has also had his invention put to a practical test. The improvement consists in the boiler being provided with "double-return" tubes. In Figs. 1 and 2 we give a front elevation partly in section and a side sectional elevation of one of these boilers, as recently fitted in the steamship "European," a vessel built in 1850 by Messrs. Smith & Rodger, of Glasgow, and which has recently had her compound engines converted into the quadruple-expansion type, and this new boiler supplied by Earle's Shipbuilding and Engineering Company, Limited, Hull.

It will be seen that the principal feature of Carson's improved multitubular boiler consists in the provision of two distinct set of tubes, the lower ones being 3in. in diameter, and the upper ones 5in. in diameter. The gases first pass from the combustion chamber to the lower tubes, and then through the upper ones on their way to the funnel. It is therefore likely that by this arrangement the temperature of the escaping gases will be considerably lower than in the ordinary marine multitubular boiler, and thus economy of fuel will be effected. Careful experimental trials and actual practice in ordinary working confirm this conclusion. The boiler, which is 13ft. in diameter and 9ft. long, has two corrugated furnaces 3ft. 5in. diameter, with a grate surface of 38 square feet and a total heating surface of 1,500 square feet. This boiler burns 20·3lb. of coal per square foot of fire grate, and is said to evaporate 10·1lb. of water per lb. of coal, calculated at an absolute pressure of 195lb. These results, if correct, are very satisfactory. Apart from economy of fuel, this design of boiler has an important advantage—viz., in equalising the temperature of the boiler when steam is being raised. The circulation of the water is ensured by the gases at their maximum heat passing through the lower set of tubes, and it will be seen that these tubes are so arranged that there is scarcely any water in the lower part of the boiler which does not have heat directly transmitted to it.

A HANDY MEASURER.

THE illustration given below shows an ingenious little instrument brought out by Messrs. O. Berend & Co., of 61, Fore Street, London, E.C., which will no doubt prove useful to engineers and others as a substitute for the

ordinary measuring tape, especially for long distances. By running the edge of the disc or distance wheel along the article to be measured, the number of revolutions are registered by the counter. As the distance wheel has a circumference of 8in., two-thirds of the number of revolutions are the number of feet measured.

THE INSTITUTION OF NAVAL ARCHITECTS.

(*Continued from page 280.*)

THE first paper read on the 19th inst. was by Mr. J. H. Biles, on

SOME RECENT WARSHIP DESIGNS FOR THE AMERICAN NAVY.

This paper gave an excellent idea of what was being done by the Americans in warship building. The keel of the first modern American warship was laid in 1883, and it was not until the end of 1889 that any considerable further additions were arranged for; but there are now under construction seven cruisers and seven armoured ships. With the aid of well-drawn diagrams and carefully prepared tables, the author gave the principal particulars of the "Chicago," the "Boston," the "Atalanta," the "Baltimore," the "Charleston," the U.S. cruiser "Philadelphia," the armour battle-ship "Texas," the armoured cruiser "Maine," the armoured coast defence vessel "Monterey," and the coast-line battle-ships, "No. 1," "No. 2," "No. 3," "Indiana," "Massachusetts," and "Oregon." Some particulars given of these vessels are as follows:—

	Length.	Breadth.	Draught.	Displacement.	I.H.P.	Speed.
	Ft.	Ft.	Ft.	Tons.		Knots.
Chicago ...	315	48	19	4,500	5,000	15½
Boston ... Atalanta ...	270	42	17	3,189	3,500	15½
Baltimore...	310	48½	19½	4,392	10,064	20·1
Charleston..	300	46	19⅞	4,010	6,666	18·2
Philadelphia	310	48½	19¼	4,324	8,815	19·7
Indiana ... Massachusetts..... Maine.....	348	69¼	24	10,200	9,000	15

The "Texas," "Maine," and "Monterey" have machinery of 7,600, 9,000, and 5,400 i.h.p. respectively, and the speed expected in each case is 17, 17, and 16 knots.

The author also described several other interesting vessels built or intended to be built for the United States Navy, clearly showing that the American ship designers and builders can produce vessels equal to the best European practice.

Sir Nathaniel Barnaby commenced the discussion by referring to the United States warships of twenty years ago. Though they were not successful in getting the expected speed, yet they were nevertheless formidable antagonists. At the present time we can discuss their proposed armament in a friendly manner. In the proposed coast-line battle-ships the turrets are so low that there will be great difficulty in working the guns at sea. They have adopted thin armour, but here, he thought, it had proved disappointing. The "No. 12" ship is said to have a coal capacity on designed draught of 750 tons, but a total capacity of 1,500 tons, and he wished to know the draught when she was fully loaded. He argued that it was doubtful policy to build ships of this class in this country.

Sir John Hay said that the United States had dropped out of the first-class naval Powers, but were likely to retrieve their position. Lord Brassey ought to reconsider his position with regard to the Atlantic trade now that the other side is making such advances. As they seem to beat us in speed, we ought to build more speedy and powerful ships. We must consider our navy by the light of American advance as well as with regard to Europe, especially as our North American possessions ought to influence us in the same way as Australasia did in the time of the Russian scare.

Admiral De Horsey had two points to comment upon. The author showed that water-line armour was retained in spite of Lord Brassey's opinions. The first thing was to float, and the water-line must therefore be protected. Even if ships are rolling, repairs may be done above that line. With regard to the coal endurance, he wished to know if the central screw working at low speeds while the side screws run idle would not conduce to great economy.

Mr. W. H. White, the Director of Naval Construction to the Admiralty, was averse to saying much because of his official position, which debarred him from deeply criticising foreign ships, especially when they were built more or less from his designs. The United States have been acquiring for years the most detailed information as to European practice, and he was proud to say, they did not adopt rival designs, but followed our lead. They not only have begun to build the ships themselves, but they also produce all the necessities for their manufacture, and will produce results that will compare with or even rival ours. They have gone on the policy of entire publicity, and Mr. Biles has summarised all that is known. Passing to the consideration of the designs, he first dealt with the armament. In some of their vessels the 8in. guns were arranged to fire over the turrets of the 13in. guns. He would be sorry to be in the lower turrets in the heat of action. In these vessels a moderate freeboard is associated with high speed. They have a coal capacity that would sink the belt armour below the water-line when they were fully loaded. This might be all right as long as the bunkers gave protection against shot. The speed is associated with the loading, and their coal capacity on designed draught is very little. Our coal loading for maximum speed is very much greater, so that we have a decided advantage. The speed also depends on the development of power, and that depends on the draught. In our recent trials we obtained a speed that would require much greater pressure of draught in the American vessels. The difficulties in reckoning the coal endurance depend on the method of calculating the weight of coal burnt per horse-power. This amount has considerably exceeded that derived from mercantile practice in every warship in the world. We want experience, and experiments are now being made to clear this up. This feature is especially notable in comparing "No. 2" and "New York" and our "Blake" and "Edgar." The sustained sea speed of the latter vessels is taken at 17⅓ knots, being some 2½ to 3 knots less than trial speeds. In a similar way the American officials will have to be more moderate in their estimates. At the present we have preferred twin-screw ships. The American ships are armed on a very lavish scale. To carry the necessary ammunition great reduction must be made in other ways.

Admiral Colomb remarked that a large part of the stem of the fore foot of the coast-line battle-ships had been cut away with the idea of increasing the manœuvring power. According to his experiments this would rather tend in the opposite direction, especially when the ship has headway, since the pivot point is moved further aft and the leverage is reduced. The object might be attained when the vessel moves from a stationary position. As for the increase in rudder area, it must be enlarged by increasing the depth of the rudder, as horizontal extension soon attains a limit of usefulness.

Mr. Hughes described his experience on board the "Huascar" on a certain memorable occasion. After mentioning the disasters in the turrets he spoke of the water-line. Not a single shot struck them there, and all the plugs of various shapes that had been prepared were useless. It was the fighting position that was most important.

Mr. Martell desired to have some information about the scantlings in these ships. Did they save weight and space by reducing them below the size used in our own ships?

Captain Long asked what was the difference in weight between the three engines for three screws and the engines for twin-screw ships.

Mr. MacFarlane Gray discussed the economy of triple and twin screw ships, and of triple-expansion. He thought that as less power was used to drive the central screw when proceeding at low speeds, less coal would probably be consumed. In new designs for ships with triple-expansion cylinders the high-pressure cylinder should be placed aft, and the low-pressure cylinder forward, so that the latter could be thrown out of gear when steaming at low speeds. This would give a great advantage, as the back pressure in that cylinder would be eliminated. It is just as economical to discard the low-pressure cylinder if the reduction in speed be the same as the ratio between the diameters (not the areas) of the high and low pressure cylinders. An example was given by the speaker to prove this.

Mr. Sidney W. Barnaby stated that in torpedo boat trials he let one screw run idle at low speeds, and found a decided economy in coal. In a trial lasting five and a half hours the consumption of coal was 1⅔lb. to 1¼lb. of coal per horse-power. There would certainly, he thought, be an economy in triple-screw vessels.

Mr. White explained that they preferred twin-screws, because in the latest designs they had two engines on each shaft, so that, at low speeds, one engine of each could be shut off.

Mr. Howes did not think that "No. 12" ship could overtake the "City of Paris." The vessels can get up very high horse-power, but cannot maintain it, as the engines cannot endure it for long. Further, it would require much training and skill in getting up and keeping steam. The engines were only designed to maintain half-power.

Admiral De Horsey thought it might be advisable to thicken the armour above the water-line instead of below, as shown in some of the diagrams. This remark he threw out as derived from what Mr. Hughes had told them of the "Huascar."

In reply, Mr. Biles stated that the extra draught in "No. 12" ship was 3ft. when her coal bunkers were full. This vessel, he said, in answer to Mr. White, was longer than the "Edgar," and has 13 per cent. more heating surface; this was equivalent to endurance in speed, and the vessel is faster. Otherwise, the displacement is about the same. He had given particulars of the coal endurance as estimated by the Americans, and he had not attempted to verify them, but had simply trusted to the particulars given him. The scantlings, he informed Mr. Martell, were about the same as in our own ships, according to what he had seen.

The President commented shortly on this paper. It was fortunate, he observed, that the Institution was able to obtain and publish this information. If it had been done by Parliament there would at once be cries that the legislature was acting the part of an alarmist, whilst the course that had been adopted would cause fair and impartial consideration. The whole matter reminded him of the old song, "We don't want to fight, but, by Jingo, if we do." The United States had acted in a most frank and friendly manner, so that we should know what we had to meet in case of hostilities, though he hoped they might never come. He hoped that the most cordial thanks would be conveyed to Mr. Secretary Tracey, and to the United States Bureaus of Construction and Engineering.

The second paper read on Thursday was by Professor Vivian B. Lewes, on

BOILER DEPOSITS.

The author gave several examples of explosions or collapse due to a new form of deposit which originated with the introduction of high-pressure steam. Analyses were given of the oil used, and of the scale and deposit. The scale from the tubes contained 21·06 per cent. of organic matter, whilst the deposit over it contained 50·20 per cent., and quite half of this was "valvoline," the oil used, in an unchanged condition. It was found that the valvoline was carried over by steam at temperatures far below its boiling point. It is therefore carried by the condenser water into the boiler, where it floats as a scum, which gradually becomes weighted by small particles of the salts that separate from the water. When the scum attains the same specific gravity as the water, it is circulated by convection currents till it meets with and sticks to some surface, which is quite as often on the underside of a tube as on the top. In this it differs from other incrustations. This deposit is an effective non-conductor of heat, especially when it becomes blown up into a spongy mass by overheating. During the last stages of overheating, when the boiler collapses, the organic matter is burnt away, and the comparatively harmless-looking calcic and other salts are left. It is curious to note that this deposit contains a large percentage of copper. Some experiments were performed by the author before an appreciative audience, to show the non-conducting power of this deposit. Two vessels containing equal amounts of water were heated by a blowpipe flame. The one, a clean vessel, quickly boiled, but the bottom of the other, which was coated with the deposit, was raised to a bright red heat before the water boiled. In some cases, the experimenter said, a hole was melted in the bottom before the water was even warmed. Reference was made to the use of sodic fluoride as a precipitant. Professor Doremus advocates its use, as being small in weight and having a rapid and perfect action.

The discussion on Professor Lewes' paper was opened by a controversy as to whether Mr. Ward should be permitted to read extracts from a paper presented to another society. As it was against the rules, and as the extracts were from a paper read by Professor Rogers in 1884 before the American Association for the Advancement of Science, and dealt generally with the subject of boiler deposits, this addition to the paper was not heard.

Mr. Corry said that the author had explained a probable cause of many explosions otherwise inexplicable, as the water was well above the furnace crowns. The idea was not quite new, but it had been clearly demonstrated. It was best to avoid oil in the boilers, and for that purpose no oil should be used in the cylinders, only the piston rods being swabbed with oil occasionally. In his experience the cylinders thus treated were as good as ever. It is best to use fresh water.

Mr. Birt had had a similar experience to the author, and his design for the exploded boilers had been called in question. It was proved that the design was good, and that oil was probably the cause of the damage.

Mr. J. T. Milton cited a case in which the boilers were filled with fresh water and the oily deposits took place very slowly. In the hottest part, near the fire-bridge, the plates buckled, whilst elsewhere they remained sound. This seemed to show that the greatest danger was where there was the greatest heat. Destruction of the plates, he thought, would take place quicker with salt water, as the deposit would form faster.

Mr. Wilson took exception to the author's statement that lubricating power of mineral oils increased with their specific gravity.

Mr. Fothergill thought the paper took the chemist's standpoint too much, and that very few explosions could be attributed to oily deposits. It was no wonder that the furnaces came down when an excessive amount of oil was used in the cylinders, but he thought that some must be used. It is no use to look for scale after the boilers have come down, as it peels off. The experi-

Digitized by Google

ments were performed at too high a temperature. He would like oil merchants to give the vaporising point of oil or the lowest temperature at which it gave off vapour. The flashing point and other details they give is of no use to engineers. His point was that excess of oil must not be used in the engine, and then no mechanical appliances are required to keep it out of the boiler.

In reply to the discussion, Professor Lewes wished them to understand that he did not claim originality, but that he had endeavoured to explain a somewhat obscure point and to add an appendix to his previous paper. The statement about specific gravity certainly required correction, but it was specially stated that his paper was subject to revision. In reply to Mr. Fothergill, he said that he based his opinion on thick scaling and the absence of scaling tool marks, so that the peeling off did not affect the question.

The third paper that was on the list for Thursday afternoon was by Monsieur M. Marchal, on a

Study of Certain Phenomena of Compression.

This was taken as read, but Mr. White stated that it was an attempt to form a theory of the behaviour of projectiles when under compression. The experiments on which the theory is founded were carried out under static conditions, and also by firing projectiles against armour plating. The author had given a summary of conclusions, and these tend to show that his theory is confirmed by his experiments. The paper was of such a nature that it could not be profitably read or discussed at the meeting, but was nevertheless extremely valuable. The paper is divided into sections, which deal with:—The general form of bodies considered; distinctive character of the effects observed; theoretical considerations on fracture by crushing, and examples of their application; influence of curvature on direction of fracture; observations on the deformation of cylinders under compression; mode of deformation of cylindrical projectiles; form of fractured fragments of projectiles; ogival headed projectiles show two forms of fracture; production of longitudinal cracks require less force than that of oblique cracks; relation of height and diameter to fracture; relation of force of impact to direction of rupture; form after crushing; crushing of spherical and cylindrical projectiles; curves showing effects; distinction between compression and crushing; and conclusions.

On Thursday evening Mr. A. F. Yarrow read a paper, entitled

Boiler Construction Suitable for Withstanding the Strains of Forced Draught, &c.

For the consideration of this paper the whole evening was set apart. It was a long one, and was copiously illustrated by specimens of the tubes, plates, and boilers referred to, as well as by the actual apparatus by means of which Mr. Yarrow performed his experiments. We shall publish the paper *in extenso* in a later issue, and will therefore only give now a brief abstract of it.

The quality and best material for boiler tubes was first dealt with, samples being shown of tubes flattened and bent without cracking, these being tests to which all tubes should be subjected to show sufficient ductility and elasticity. Expanding by a taper drift was condemned, the drifts used being parallel with rollers having slightly enlarged ends to cause a shoulder inside the plate and a bead outside, care being taken to ensure uniform expanding. Screwing the tubes in position had been tried and abandoned, likewise the use of ferrules. Stay tubes had also been given up for many years on account of their rigidity. The holding power of the ordinary tubes from experiments made showed a margin of safety of 20 in holding the plates together. Stays in water space should allow a free movement to the box and allow for change of temperature. Experiments showed that when the stays were fixed to pass through stuffing-boxes in the shell plate, they moved in and out with every reduction or forcing of the fire. A leaky boiler, after failing eight times, had held tight on adopting this arrangement. Experiments were described for testing the distortion of tubes during heating, by means of rods fixed in the tubes with their free ends through the smoke-box. These ends moved considerably, showing bending of the tubes until about 15lb. of steam was formed, when a back movement showed straightening due to curvature of the tube plates. The distortion of other parts of the boiler was also demonstrated. Respecting air pressure in forced draught, locomotive practice was cited where an equivalent of 10in. of water pressure was used. Limiting the pressure involved a rigid boiler, and this was bad. It was important to steam a new boiler gradually, and never to "rush" steaming at any time, but to light up slowly, with plenty of water, and blow out the surplus as the temperature rose. The result of investigations with thin tubes in thick plates and in thin plates was then given. Proof had been found that after much expansion and contraction the tube end became permanently smaller than the hole, this effect being greater with a thick tube plate than with a thin one. A $\frac{1}{16}$in. tube in a 2in. plate leaked beyond use after eighteen heatings, but a $\frac{5}{8}$in. tube in a $\frac{7}{16}$in. plate held tight after forty heatings; hence it was believed that for iron and steel plates it was better to keep the plate as thin as possible. Further experiments were undertaken to show the curvature of a tube plate in consequence of unequal heating of opposite sides of the plate due to their respective contact with fire and water. This curvature was as much as $1\frac{3}{8}$in. from the flat position. The change of shape produced in round holes after repeated heating and cooling had been measured. The holes became distinctly oval and distorted, thus showing the existence of severe internal strains. This was less with thin plates than with thick, showing other reasons for the adoption of thin elastic plates when of steel. In order to illustrate the advantage of copper over steel plating, an experiment was performed before the meeting with two plates of these materials, each 24in. long, 2in. wide, and 1in. thick. They were gas-heated on one side, water being kept over the other, and the distortion was magnified by levers and shown by pointers. As the pointers moved curves were plotted out—first, as the temperature increased; secondly, as it decreased, due to currents of air fanned across their surfaces. The distortion was very much greater with the steel than with the copper plate, and it was concluded that copper was altogether about four times as good as steel. Galvanic action when copper was used had never been serious, and the final conclusions drawn were that boiler evils, especially that of leaky tubes, would be overcome by "copper" and "elasticity."

Mr. Durston, Engineer-in-Chief of the Navy, rose to open the discussion. He first pointed out that Mr. Yarrow's experience had been limited to torpedo boats, with a single boiler, and not to the working of a group of boilers, where there was a difficulty in ensuring that each boiler should receive its proper share of feed-water or give out the same volume of steam. He soon made it evident that, although he agreed with Mr. Yarrow's reasoning and experiments, he dissented from the conclusions drawn. He believed the whole trouble of leaky tubes was in the overheating of the tube plate, caused by imperfect water circulation, owing to the close pitching of the tubes. There was too much heating surface and insufficient water space; hence, in spite of all possible precautions, overheating must take place, and leakage ensue. The Admiralty practice in fixing tubes was to make the ends a driving fit in tube plates, to expand the fire-box ends with a taper drift, working against rollers with an equal taper opposite in direction, thereby ensuring uniform and parallel fixing, the end of the rollers being pushed to about $\frac{1}{4}$in. beyond the water-side of the plate to form a small shoulder; while at the smoke-box end no shoulder was formed, and the tubes were not drifted tight, in order to allow some freedom for longitudinal expansion. The drift with enlarged ends had been used in the dockyards, but given up. It necessitated destroying the tubes before they could be removed, and during a steam trial a boiler tubed in this way had leaked worse than a similar boiler where plain rollers had been used. Screwing the ends of the tubes into the plates had also been tried, and with similar results. Stay tubes were necessary to meet the large forces set up when the tube plates and tubes became unduly heated. It should not be overlooked, when making comparisons, that a locomotive boiler worked for much shorter lengths of time than marine boilers, and were more easily kept in good repair. In speaking of working under air pressure, Mr. Durston pointed out that with badly worked fires, such as they were always subject to, a high pressure of air caused more mischief than a low one. He considered a draught vacuum in the smoke-box would do less harm than an excess pressure in the stokehold, since in the former case the air and gases were drawn through the tubes, while in the latter they rushed through them. The Admiralty followed the practice of filling the boilers to a high water level before lighting fires, and then blowing out as the temperature rises, while they also considered uniform heating was increased by taking in the feed-water above the furnaces. As far as possible, boilers were always steamed slowly, and in new machinery no condenser water was used for the first three or four hours. In some recent experiments at Portsmouth, they had taken an old locomotive type of boiler from a ship fitted with ten such boilers, and which had failed to work satisfactorily, and had steamed the boiler on shore, using fresh water, without any trouble. It was found that the tubes became as dirty and choked with twelve hours forced draught as with thirty-six hours natural draught. The speaker did not consider the experiments of Mr. Yarrow on thick and thin tube plates, and the curving of tube plates, came within practical limits or represented practical conditions. In the trial of the "Nile" boilers, there was scarcely a leaky tube under a 2in. air pressure, although the boilers were 16ft. diameter, with four furnaces having a common combustion chamber. It was true they had tried the effect of plastering the tube plate and ends, but the experiments were performed, not, as had been suggested, with a view to its adoption, but to discover if the boiler would continue to work so long as the tube plate and ends were kept cool. The result confirmed his opinion that, by avoiding overheating, all difficulty would be overcome. In concluding, the speaker referred to the increasing confidence of naval officers in the use of forced draught and its efficacy to maintain a cool stokehold, otherwise impossible, and to aid combustion. He also related some Admiralty experience with a boiler where the vertical centre row of tubes over each furnace had been removed, and the furnace crown covered with brick, causing a very satisfactory and tight working. The same practice, followed in a locomotive type of boiler, caused a removal of 10 per cent. of the tubes, but gave a good working result and avoided leaks.

Mr. Fothergill criticised the arrangement of Mr. Yarrow's boiler, and gave some account of his experience with forced draught. He did not consider it a mistake to have a rigid tube plate; hence he should not abolish stay tubes, but would keep the tube plate stiff and the tubes flexible. In the boiler described by the author it was evident that the heated gases passed straight to the top rows of tubes only, thus causing unequal heating and expansion. A deflector at the furnace back would prevent this by causing more equal distribution and destroying the disastrous direct impact of the heated gases. It should be remembered that the difference in air pressure in the stokehold and funnel was caused by the resistance to be overcome by the air in its passage through the boiler; this varied a great deal, and gave apparently misleading results. His six years' experience had taught him that with a moderate air pressure of $\frac{3}{4}$in. no damage was done, but he did not believe any boiler would stand prolonged working with such pressures as $1\frac{1}{2}$in.

Mr. Martin concurred with the views expressed by Mr. Durston as to overheating being at the root of the trouble, and declared himself as a "hot tube plate man." His first experience with the locomotive type of boiler had been in some trials of one of Thornycroft's first-class torpedo boats at Portsmouth. The run had been satisfactory, when the boiler suddenly ran short of water, became overheated, and an outburst of water and flame caused severe injury to the stokers. Yet, by keeping up a plentiful supply of feed-water, they magaged to work the boiler back without serious leakage at the tubes. In another case, with a vessel of the "Sharpshooter" class, they had run a good two and a half hours' trial, when, on increasing the air pressure, the boiler suddenly became over-heated, and in an instant nearly emptied itself of water through spaces formed between the tubes and the tube plates. He had recently heard of some experiments made thirty years ago on the Dublin Main Railway Line, when it was found, by means of tubes through the boiler back, that there was often no water, but steam only, near the tube plate, thus showing bad circulation. In his own practice he had placed a propeller inside a tube passing into the boiler, and propelled the water towards the front tube plate. While the arrangement worked no leaking was seen, but as soon as it stopped, due to a breakdown, the plate became overheated, and the tube at once began to leak. He had found that brass rings, tightly fitted in cast-iron safety valve casings when new, had become free after some service. This would serve as another illustration of how a space could be formed between a tube and plate by a constant crushing and consequent reduction of the tube section. Plaster had occasionally been used, and had been found to prevent leakage when about $\frac{3}{8}$in. thick over the plate. He considered the crowding of tubes, and the resulting bad water circulation, was the chief cause of the evil.

Mr. Thornycroft said that much as he admired the skill of Mr. Yarrow in overcoming present difficulties, he considered there was even something to regret in it, since, by patching up an old type of boiler, it only served to delay the day when a really good boiler would be used. His own experiments had shown that forcing a boiler caused leaky tubes and hot tube plates.

M. Normand had in France tried to protect tube ends by reducing their diameter and covering them for a short length with cement, thus causing the heat to strike the tubes beyond the tube plate. His own firm had inserted short copper tubes into the ends for the same purpose, and, although they were found to protect and keep tight the tubes, the copper ends themselves fused, and the arrangement was abandoned.

Mr. Marshall gave the weight of his opinion to the importance of the spacing of the tubes. When the rows of tubes were arranged diagonally it was much better to have the greatest space in a vertical line, rather than in a horizontal one as in Mr. Yarrow's boiler. He had found that of two similar boilers working in group with others, the one having the vertical arrangement held tighter than the other. The reason why so much leakage took place in Admiralty boilers, as compared with the mercantile marine, was due to attempting to force too much heat through insufficient surface. With a single combustion chamber to four or six furnaces all the heat

Digitized by Google

had to pass through one plate pierced with many holes, while a number of combustion chambers increased the absorbing surfaces, as a result of which the plates were less heated. Dr. F. Siemens had recently pointed to the disastrous effect of the impact of hot gases upon steel plates; the plates absorbed carbon and altered their characteristics. A proper arrangement of flame boxes such as Mr. Inglis, of Glasgow, used would prevent this. It was probable that the first foot of the tube length did most of the work, hence shorter tubes should be used. M. Normand's plan of a falling water bridge for throwing the gases down had effected useful results, and what we really wanted was a larger surface for heat absorption.

Mr. Manuel thought we should not hear so much of leaky tubes in future. Marine engineers were asked to do impossible things, since they were required to put too much power in too little space. This produced excessive fire-grates, which, together with neglect of proper circulation and scantling, were the chief causes of leakage. Mr. Manuel then drew upon the blackboard a form of double-ended boiler with long fire-grates, the evils of which he pointed out. He also made some remarks, evidently intended for the Admiralty engineers present, with reference to the safety of the stokers in closed stokeholds, and the change of policy in the Navy by the reduction of the air pressure. The sketch and criticisms brought Mr. White to his feet with an indignant denial of the assumptions and conclusions Mr. Manuel had made, and an explanation that the difficulties in the boiler referred to were inherent to its special type. The incident did not close until further emphatic remarks had been made by the speakers.

Mr. Martell, as a naval architect, desired to protest warmly against the growing demands of boiler constructors. The time was when boilers were made for ships, but now ships were made for boilers, and, as a result, shipbuilders had been forced to give up their scantlings and stringers to make boiler space. This policy could be carried too far.

Admiral De Horsey wished to draw attention to some experience with a tube plate covered with a non-conductor, which had worked well while the coating remained. He wondered Mr. Yarrow did not use a hanging bridge to deflect the hot gases. In a small steam launch he possessed, the tubes had required renewing every month until the adoption of a bridge, when they lasted ten months.

Professor Lambert desired to point out that no attempt had been made to measure the forces producing the distortion of the tubes and plates in Mr. Yarrow's experiments, but only to measure their effects. It was evident the disturbing forces would be very great, and could not be neglected. He heartily congratulated Mr. Yarrow on the way he had faced the question.

Mr. Yarrow made his reply somewhat brief owing to the lateness of the hour. He could not, he said, fully agree with the criticisms of Mr. Durston, but felt sure all would be taken in good part. The method of measuring air pressure in forced draught was a misleading one, since one boiler could be more forced with a 2in. air pressure than another boiler with 3in.; it was a question of resistance to passage through the boiler. He could not believe tubes could keep as tight with thick plates as with thin ones, and he had found steel boxes give endless trouble while copper boxes worked quite successfully. He considered the 3in. tube plate referred to by Mr. Martin, and the $\frac{9}{16}$in. plate of Mr. Marshall, too thick; they should not be above $\frac{1}{2}$in. He never worked a new boiler to full power at first steaming, but only at the second trial. The use of copper in place of steel would give the greater absorbing surface wanted by Mr. Marshall, and he could only believe that its greater use, in spite of its large cost, would do very much to overcome the difficulties he had dealt with in his paper.

A very warm vote of thanks was accorded to Mr. Yarrow by an audience evidently much edified by his experiments and illustrations, and grateful for the large amount of trouble and expense he had incurred.

(To be continued.)

AN IMPROVED BAND SAW GUIDE.

Notwithstanding the continual increase in the uses of band saws, a great deal of dissatisfaction is caused by their frequent breaking. A large proportion of such breakages are attributable to the unsatisfactory methods of guiding the saws, a favourite method being to use a stationary piece of wood or metal, to take the back thrust. It is obvious that this must engender a considerable degree of heating through friction, and cause the saw to expand and crystallise at the back. This action after a time brings about the breaking of the saw. The use of oil or grease between the rubbing surfaces is not desirable, as it tends to destroy the rubber on the saw

AN IMPROVED BAND SAW GUIDE.

Constructed by Messrs. J. Sagar & Co., Wood-working Machinists, Halifax.

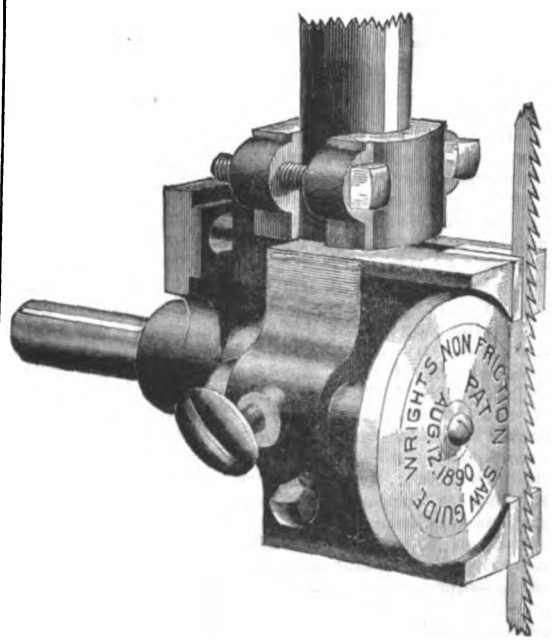

Fig. 1.—Showing Guide Complete.

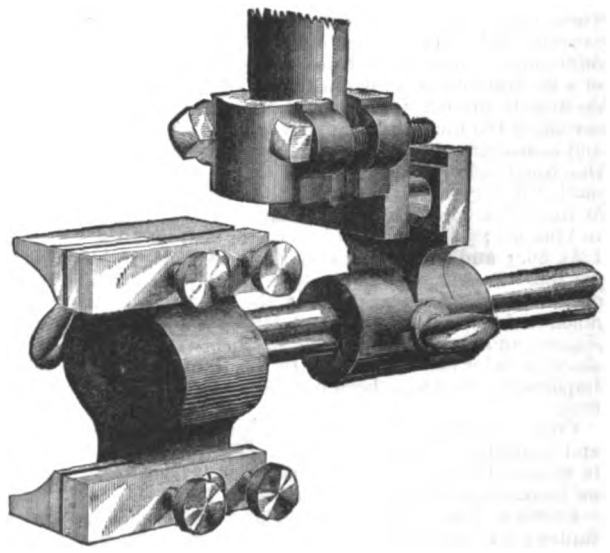

Fig. 2.—Showing Guide with Anti-friction Disc Removed.

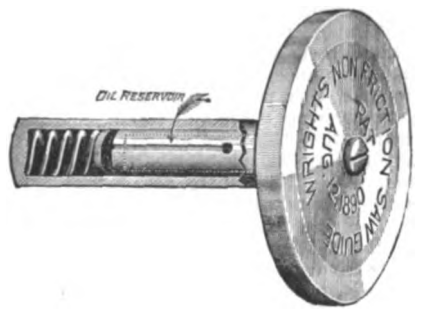

Fig. 3.—Showing Anti-friction Disc.

wheels. More recent attempts at guiding the saws, such as the use of metal pulleys or runners to take the back thrust, have been steps in the right direction, but none of these provided any side support for the saw. In the "Wright" band saw guide, which we illustrate herewith, Figs. 1, 2, and 3 represent respectively the complete guide, the guide with anti-friction disc removed, and the anti-friction disc partly in section. In this invention the above-mentioned defects would appear to have been successfully and simply remedied, for, as will be seen, this guide consists of a metal body, having two pairs of steel guide plates and a steel disc respectively for guiding the saw laterally and for taking the back thrust. The disc is mounted upon a spindle capable of revolving in an oil reservoir, and is caused to revolve by slight frictional contact with the saw itself, at the same speed as the saw is moving. The disc, which is the only wearing part, will, we are informed, last for a considerable time, and can be easily replaced when worn out. The makers of this guide are Messrs. J. Sagar & Co., wood-working machinists, of Halifax.

ENGINEERS IN THE ROYAL NAVY.

We understand that the increasing difficulty of obtaining, not only engineers (in the official sense of that term), but also engine-room artificers, for service in the Royal Navy is beginning to cause serious alarm at the Admiralty. We are told that the attempt made last year to obtain fifteen assistant engineers from approved engineering establishments and technical colleges was a failure, and yet, undeterred by this, the Admiralty propose to advertise twenty-six similar appointments to be open for competition in May next on the same conditions. Advertisements are also to be found in the newspapers for engine-room artificers, coppersmiths, boilermakers, and fitters, and agents seem to be appointed all over the country for the purpose of trying to engage suitable men. These efforts, however, do not seem to be successful, as we recently heard of a commission going over the country, and spending a considerable amount on travelling expenses, and on their return to the Admiralty were only able to report that they had captured two candidates. When every other class of occupation is overcrowded by applicants, and when all the lines of steamers in the mercantile marine have long lists of fully qualified men waiting for vacancies, there must be something wrong in the arrangements of the Navy when there is so much difficulty in obtaining sufficient men to meet the requirements of the service.

Let us consider, in the first place, the cases of the engine-room artificers. These men find that when they enter the engine-rooms of the Royal Navy they must abandon all hope of promotion. They are "artificers," and can never become "engineers." When we remember that all those who enter the mercantile marine are at first exactly like themselves, but that if they conduct themselves properly, and take advantage of what opportunities they may have for self-improvement, they may rise through all the grades, and become superintendent engineers or managers of engineering establishments, it is not to be wondered at that the more hopeful and the freer career proves the more attractive. Any position which gives no hope of improvement must always be depressing.

With regard to the engineer officers even, they are in a very depressed condition. The pay is small, and the status is inferior to that of the naval officers, and consequently it is found that the best of them prefer to enter private service. We recently, indeed, had the curious spectacle of the Engineer-in-Chief of the Navy resigning his post and entering a private firm. Under proper conditions this would have been impossible. The present conditions must be so modified as to attract really good men. The recent free competition for the positions of assistant engineers was, no doubt, a step in the right direction, but the theoretical examinations seemed far too difficult; in fact, that is the fault of all the examinations connected with the Admiralty. They are conducted by men who are good mathematicians, but who, as a rule, are not engineers, and who consequently have little idea of the requirements of engineers. When we consider how little mathematical knowledge is required by sea-going engineers, we think a test might be devised which would secure the best men for the work to be done. We do not think that this is likely to be the case if a knowledge of pure mathematics, or even physics, is to be preferred to good workshop practice.

With regard to the engine-room artificers, some avenue ought to be opened up whereby at least the best of them might be able to obtain the position of engineer officers; in fact, in every service we believe that unless men get the chance of rising there will be discontent and difficulty. When so many things are being inquired into we think that some Member of Parliament ought to suggest that a special committee be appointed to inquire into the conditions of service in the engineering department of the navy with a view to devising some means of improvement.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 24th March, 1891.

Iron.—The situation here is improving, and orders continue to come in plentifully. The prospect is good, but there is no change in prices for the present. The quotations fixed by the Paris Syndicate were 136s. 6d. per ton for bars, and 144s. 6d. for joists. The commercial prices were 124s. 6d. per ton for bars, and 132s. 6d. per ton for joists. These rates do not leave much profit for the iron merchants, as producers' quotations are high and have a tendency to rise on account of the continued dearness of fuel and the prospect of a general miners' strike in the spring. In the Meurthe-et-Moselle district the wrought iron market is dull, but several of the foundries are fairly busy, and the steel works and constructors' shops have plenty of work on hand. In the North affairs have a much brighter aspect and the market is very firm. Last week the best bars were quoted at from 112s. 6d. to 116s. 6d.; ordinary joists, from 116s. 6d. to 120s. 6d.; joists with wide flanges, at from 132s. 6d. to 136s. 6d.; and those over 12in., from 144s. 8d. to 148s. 6d. per ton. It seems probable that these prices will be increased 4s. or 5s. per ton. In the Pas-de-Calais district much activity is being shown. A large steel works has been started, and the establishment of tool works and boiler shops is under consideration. In the Haute-Marne several important orders have been booked, and the prices are very firm.

Coal.—Great activity still continues in mining operations and quotations are generally firm. The production of fuel in France during the year 1890 was 26,327,008 tons, being an increase of 2,423,799 tons on that of 1889.

Copper, Tin, and Lead.—There has been a general falling off in the prices of these metals, and the market is very weak. Best Chilian copper in bars is quoted at £56 8s., ordinary Chilian bars at £54 10s., and "best selected" ore at £59 2s. per ton. Billiton tin has decreased in value 10s. per ton. Lead is officially quoted at £13 2s. per ton.

Exportation of Cast Iron.—The following statistics, which have been taken from the documents of the French Custom House, show a considerable decrease in the exportations of cast iron from France during the month of January of this year as compared with the same period of 1890:—

	1891. Tons.	1890. Tons.
Total importation of cast iron	1,973	385
Total exportation of cast iron	5,693	15,908
Temporarily exported (to be re-imported)—		
Forge pig	3,566	3,726
Foundry pig	2,938	6,121
Re-exported (after being manufactured)—		
Forge pig	1,808	2,900
Foundry pig	3,146	2,176
	17,151	30,831

Launch.—La Société des Forges et Chantiers de la Méditerranée has recently launched from its yards at La Seyne a large steamer, "L'Espagne," built for La Société Générale des Transports Maritimes. This vessel is 397ft. in length over all, with a beam of 42ft. She is built of steel, and has a displacement of 6,600 tons; her engines, of 3,000 horse-power, are on the triple-expansion system, and the speed calculated upon should be 15 knots at the trials and 14 when running in ordinary service.

BERLIN, 23rd March, 1891.

Trade at Stettin.—According to the recently published statistics of the maritime trade of Stettin, the total import of Stettin has increased from 1,384,040 tons in 1889 to 1,424,970 tons in 1890, the export from 568,268 tons in 1889 to 617,961 tons in 1890. The import from the harbours belonging to the German Commercial Union, Sweden and the United States showed a considerable increase, and a corresponding decrease from Russia, Great Britain, Italy, Norway, and British Australia. The principal articles of import were:—Oats, timber, pig iron, iron ores, coal, herrings, and petroleum. The export to Great Britain, North America, Spain, Italy, Russia, and the harbours of the Union increased considerably, and decreased considerably to Belgium, France, Holland, Portugal, the Brazils, and Denmark. The principal articles of export were:—Raw sugar, loaf sugar, cement, flour, potato-flour, timber, zinc, coal, spirits, and wheat.

German National Exhibition in Berlin.—There appears to be a general desire in industrial circles to have a large exhibition of national industry here as soon as possible, and a movement has been started by the Osnabrück Chamber of Commerce to create the necessary interest in the matter. It appears, however, that the associations of the larger industrial establishments in Germany are not entirely in favour of the project. It is probable, therefore, that, unless the Government takes the matter up, it will be indefinitely postponed. The town of Berlin itself would, no doubt, be pleased to have such an exhibition, and would in due time be quite willing to grant a liberal subsidy.

Professor Helmholtz.—Professor Helmholtz will celebrate his seventieth birthday on August 31st. In honour of the anniversary a marble bust of Professor Helmholtz will be prepared, and it is proposed that there shall be a Helmholtz Medal, to be bestowed on the most eminent German and foreign physicists. An international committee has been formed for the purpose of carrying out these schemes.

VIENNA, 23rd March, 1891.

The Iron Market.—Little alteration has taken place in the iron market since last week. Prices generally are scarcely maintained, and there is a general stagnation of trade, which will only disappear when building operations resume their full activity. Hopes of such an increase of trade have prevailed for some time without fulfilment. Machine works are busily employed, and are well provided with raw material. Electrical industries are at the present time giving good employment to machine works. The Brünn Machine Works Company has recently received an order from Messrs. Ganz & Co. for steam engines, with a total output of more than 1,500 h.p.—The large refining works and rolling mills of the Austrian Hungarian State Railways Company have made an output during the past year of 29,109 tons of rails, 4,998 tons of girders, 4,772 tons of iron for constructive purposes, 7,659 tons of merchant iron, 3,546 tons of thick sheets and boiler plates, 2,113 tons of fishplates, 1,977 tons of thin sheets, 1,632 tons of axles, and 3,623 tons of tyres. The total production amounted to 50,000 tons of refined iron, and 15,187 workmen were employed.—A company has been formed with a capital of 800,000fl., which is afterwards to be increased to 1,000,000fl., for the purpose of working the antimony and gold mines of Mileschau.

The Coal Market.—Business has become more active in every department, and, with the resumption of traffic on the Elbe, orders are continually increasing, both in number and amount. The West Bohemian Miners' Union held its general meeting last week, and the balance sheet for the past year was produced. The net profits for the year amounted to 321,719fl., an excess of 20,000fl. over those of the previous year. A dividend of 5½ per cent. was announced.

Electrical Engineering.—The Department of Public Works in Budapest has submitted to the town council a plan for the electric lighting of the city. The city has in consequence announced its wish to receive plans in open competition for this project. It is rumoured, however, that this announcement is merely formal, and that an order for the installation has been already entrusted to one of the largest firms in the kingdom.—The electrical railway which ascends the Mönchsberg, near Salzburg, has carried 66,712 passengers and more than 1,000,000kgr. of goods up to the end of last year. The net profits amounted to 417,411fl. It has been decided to enlarge the central station at Salzburg. The Electrical Works Company at their recent general meeting determined to pay a dividend of 7 per cent.—Messrs. Ganz & Co., of Budapest, have received the second prize for their plan for the utilisation of the water power at Niagara.—Messrs. Siemens & Halske have recently opened a fine installation for the electric lighting of the Lintz Railway Station. The installation consists of 100 arc lamps and 200 incandescent lamps.—The electric lighting of the imperial palace at Vienna is to be extended, so as to include all the rooms in the palace. The installation now consists of 2,000 incandescent lamps, and the proposed extension will add 2,000 lamps to the present number.

BRUSSELS, 24th March, 1891.

The Metal Market.—The situation becomes worse every day in consequence of railway rates, which favour the carriage of raw material, to the detriment of home production. There are at present few hopeful signs. The rolling stock of the Belgian railways is in a poor condition, and accidents happen daily which might be avoided by the renewal of the stock. Belgian manufacturers have shown energy in overcoming many difficulties, but will scarcely be able to continue their efforts with success, unless the condition of the market should improve, especially as regards the price of raw material. The market on the whole is inactive, but there is some business in sheet iron. Messrs. Dyle Baculan have an order for turntables for the Belgian Government at a cost of 200,000fr., and also an important order for vessels for Brazil.—It has been proposed in Belgian commercial circles to form a company in order to find markets for Belgian products in foreign countries. Prices are as follow:—No. 1 quality, 13·50fr.; sheet iron, 16fr.

The Coal Market.—The coal market is rather inactive. Orders for household sorts are slack, and prices of industrial sorts are weak. Reductions are made in the prices of coals for iron and glass works. Some large contracts for fuel are to be placed by the Belgian Government on the 7th of April. It will include 75 lots of 2,000 tons each of small coals, 2 lots of 2,500 tons of coal for foundry purposes, 1 lot of 1,500 tons of nuts, and 1 lot of 600 tons of coke. The placing of these contracts is awaited with some attention, as it will serve as a basis for the renewal of contracts which are on the point of expiry. The coke market is weak, and offers have been made at 17fr. to 17·50fr. per ton. Fortnightly prices are as follow:—Best *demi-grasses*, 11fr.; ordinary, 10fr.; lump coal, 15fr.; small coal, 10fr.; and patent fuel, 16fr. to 17fr. A quantity of patent fuel has been ordered for Germany, and German agents have effected some important purchases in several coal districts.

Ostend as a Port.—A proposal has recently been made to convert Ostend into a large seaport town, and to construct docks to accommodate the largest trading vessels, &c. This proposal, which is not a new one, has been brought to the front again, owing to the blocking up by ice of the River Scheld during the recent severe winter, thus closing the port of Antwerp and causing great inconvenience in commercial circles.

Electric Lighting.—The Town Council has determined to undertake the electric lighting of the city, and not to grant the concession to any company. The Town Council has been induced to carry out the work by the consideration that it would otherwise be obliged to take over the installation at a largely increased price on the expiry of the concession at the end of twenty-five years.

Hygienic Exhibition in Brussels.—It is proposed to hold an Hygienic Exhibition at the Musée Castan, Passage du Nord, Brussels, from April 15th to the 31st May next. Full particulars can be obtained by applying to the Secretary of the Exhibition, 160, Boulevard Anspach.

The Extended Use of Gas for Heating at Brussels.—A lowering of the price of gas at Brussels has tended to increase its use for heating purposes, and the consumption has now become very large, chiefly owing to the efforts of M. H. Aerts, director of the lighting department of the town. The gas authorities have determined to charge a certain price for the rent of stoves, and a list of those which are permitted to be used is given to applicants on their applying at the central offices. The stoves most in demand are those for cooking purposes, and the charge for hiring is about 10 per cent. per annum of the total value. During the hot weather the use of gas for cooking has many advantages. A large number of different kinds of cooking stoves have been invented. The Belgian Gasfitters' Association has re-appointed the committee who superintend their exhibition of appliances. This exhibition has become of increasing importance, owing to the generosity of the town authorities and to the efforts of M. Aerts and M. Pettré. Monthly lectures are given by the members of the association, and lessons in cookery by means of gas stoves are given weekly. The increased use of gas in Brussels could scarcely have been foretold some few years ago, and in view of the improvements recently effected in gas cooking stoves the extension of electrical lighting may be regarded without alarm by those interested in the use of gas.

DÜSSELDORF, 24th March, 1891.

Pig Iron.—The production of pig iron in Germany, including Luxemburg, during last month was 331,660 metric tons, as compared with 362,026 tons in February, 1890, and 348,355 tons in January, 1891. These figures show a decrease, which will probably become greater if the high price of fuel is maintained. The Rhenish-Westphalian makers of pig iron have again reduced their prices, and they now quote best foundry pig iron at 71 marks, No. 3 at 60 marks, Bessemer pig at 62 marks, Thomas pig at 48 marks, the reductions being from 1 to 4 marks. White and grey puddling pig of first quality is quoted at from 53 to 54 marks, while the ordinary brands are quoted at 45 marks.

Iron and Steel.—Steelworks in general are in a satisfactory condition, but they are hoping for new orders for the summer months. The demand for bar iron has rather increased, but the makers of girders find a deficiency of orders. Building operations have been decidedly kept back by the long and cold winter. Makers of plates of all kinds and of wire are looking for new orders.

The Late Professor R. Werner.—Professor R. Werner, a well-known lecturer at the Polytechnical School in Darmstadt, died a few days ago.

AMSTERDAM, 23rd March, 1891.

Railways.—The Minister for the Means of Communication has stated in the Legislature that he recognises the present inadequacy of the great central railway station at Amsterdam. Steps will consequently be taken to improve the accommodation in such a manner as shall do away with the numerous complaints of the companies and of the public.

A New Petroleum Company.—The American Petroleum Company has been formed in Holland under Dutch law, and has obtained the Royal sanction for its articles of association. Its capital is five million guilders. It is the outcome of a combination between the Standard Oil Company and Messrs. Herrmann, Stursberg, & Co. (both of New York), Messrs. Horstmann & Co. (of Rotterdam), and Messrs. Fr. Speth & Co. (of Antwerp), whose business will be merged into the company as from the 1st of April next, the new company taking over all their tanks and steamers.

Street Asphalte in Amsterdam.—The Corporation of Amsterdam proposes to cover several of the main streets of the capital with asphalte pavements.

Tramways in Rotterdam.—The Rotterdam Tramways Company, working a system of about 30 kilometres, under an exclusive concession from the Corporation, has done well in 1890. The directors' report shows that the receipts were 627,242 guilders, the working expenses 452,277 guilders, and the available net profit 174,964 guilders, out of which a dividend of 8 per cent. has been declared upon the ordinary shares. The company works with a staff of 386 persons, and its stud comprises 454 horses. It also has 9 locomotive engines and 116 cars. The number of passengers carried last year was over six millions.

Digitized by Google

NETHERLAND-AMERICAN STEAMSHIP COMPANY.—The company opens, as from April 1st, a new line of steamers from Amsterdam and Rotterdam, alternately every fortnight, to Baltimore. The first steamer to leave will be the "Edam." The fares will be 100 guilders first-class, and 54 guilders steerage. The demand for steerage passage is just now very great, and many applicants have to be disappointed. The company will discontinue its weekly service from Amsterdam. The steamers from that port will leave every alternate Wednesday, and Rotterdam every Saturday.

STOCKHOLM, 21st March, 1891.

EXPORTS OF WOOD PULP.—During the first two months of the present year the exports amounted to 11,708,088kgr., against 8,695,000kgr. for the same period last year and 6,646,000kgr. for the same period of 1889. The shipments during January and February comprise 4,150,683kgr. of dry and 1,163,775kgr. of wet chemical wood pulp, 3,516,520kgr. dry and 2,977,050kgr. wet mechanical wood pulp. The principal exports of all four kinds took place from the Gothenburg district.

INSURANCE OF MEN AGAINST ACCIDENTS.—The insurance of factory hands and workmen against accidents is becoming very frequent in Sweden, either at the instance of the employers or of the men themselves. The men at the Ala Saw Mills have recently been insured against accidents for a sum of 350,000kr.

NEW RAILWAYS.—The development of new railways may lead to unpleasant results for older railways. As an instance may be mentioned the Siljan Railway in Dolarne, where the receipts have been steadily declining every month since the neighbouring Falu-Röttviks Railway was opened last August.

LARGE SALVAGE UNDERTAKING.—The salvage steamer "Belos," which belongs to the "Neptun" Salvage Company, in Stockholm, and which is stationed in or about the Mediterranean, is engaged in raising the Russian passenger steamer "Grand Duke Constantin," which was stranded at Alupka, in the Black Sea, some time ago. The value of the steamer is about £60,000.

CHRISTIANIA, 21st March, 1891.

MILK CONDENSING MANUFACTORY.—Milk has gradually become an important industry in Norway. The works at the Sannesund Manufactory are now progressing, and the vital question of a good supply of fresh water will also be taken in hand shortly. The water will be conveyed from the Tunevand to the works.

THE FISHING INDUSTRY.—Questions connected with the development of the fishing industry are being much discussed at present. In the Christiania Technical Society an interesting paper was read on this subject. The author said that the treatment should commence with perfectly fresh fish, the character of which should be preserved as far as possible. Various methods were discussed, including hermetic preservation, and a new process for the drying of cod. Drawings were shown of a manufactory in which the fish were converted into dry, flat cakes, which could afterwards be given any desired shape. The capacity was about 10 tons of fish per diem. Drawings of railway carriages for the transport of live fish were also shown.

NEW HORSE-SHOES.—Lieutenant Coo, of the Royal Cavalry, has constructed a new horse-shoe, which is to be submitted to numerous practical tests. The special feature of the new shoe is the fact that its calks and clips are changeable. Tests will also be applied to shoes from the Adde horse-shoe manufactory in Sweden, for which somewhat similar advantages are claimed.

NEW RAILWAYS.—With the approach of spring the various new railways, both those already passed and those only projected, are attracting more and more attention. Uncertainty seems, however, to prevail in various directions, and even works which are in a fairly advanced condition have in places been countermanded.

COPENHAGEN, 21st March, 1891.

PROJECTED HARBOUR FOR FISHING VESSELS.—The opinion generally prevails that some steps should be taken for the advancement of the Danish fishing industries, which will not bear comparison with those of Sweden or England. An important question is that of a harbour, and some preliminary surveys have already been made. From these it appears that the various plans would entail the following expenditure:—A harbour at Klitmöller, 15½ million kr.; at Houstholm, 14½ million kr.; at Sandneshage, 11⅞ million kr.; at Hirtshals, 10¾ million kr. The possibility of providing accommodation for the North Sea fishermen at the entrance to the Limfjord at Thyborön has also been considered. An efficient dredger would cost about 320,000kr., and its annual working and maintenance would amount to about 40,000kr. Of other schemes there is the opening out of a new exit from the Ringkjöbing Firth, and of a fishing harbour at the Scaw, which is estimated to cost 2,100,000kr. As far as the Kattegat is concerned, there are two different plans for a harbour at the island of Anhalt, at a cost respectively of 465,000kr. and 590,000kr., and also for a harbour at Lessö. There are thus many alternatives, and no doubt some of them will be taken in hand before long.

MADRID, 23rd March, 1891.

THE NEW OFFICES OF THE BANK OF SPAIN.—The offices of the Bank of Spain are about to be transferred to the new and magnificent building which has been in course of construction during the past seven years. The building, which is of granite and marble, is, perhaps, the finest in Madrid, with the exception of the Royal Palace. Its principal frontage is 162 metres in length, and faces the public walk El Prado. The sum spent on its construction amounts to £600,000. Lifts and telephones have been erected, and the heating and lighting arrangements are of the most improved description. The building, if not architecturally beautiful, is at any rate free from the monotony which is not easily avoided in a long building of only three stories.

ANNIVERSARY OF THE DISCOVERY OF AMERICA.—Much activity prevails in those centres which are engaged in work connected with the celebration of this anniversary. An exhibition of antiquities relating to the discovery of America will be held in the large building which has been in course of construction for the past twenty-five years as a national library and museum.

SHIPMENT OF ORES.—The shipments of ores from Bilbao continue to decrease, but there has been no change in prices since the commencement of the year. There is a general conviction that a small diminution in prices would have no influence in increasing the demand. The statistics of shipments from the south are not so exactly given as of those from Bilbao, but it is reported that they continue at the same rate as during last year.

RAILWAY FROM OVIEDO TO INFIESTO.—The construction of this narrow gauge railway is so far advanced that the opening of the line for traffic may be expected to take place next May or June. The line has been thoroughly well constructed, and will be provided with rolling stock of the best description. It will nevertheless be one of the cheapest lines of its kind. The cost of the line, which is thirty miles in length, has been kept within the estimates, with the exception of an excess of £4,000 on the purchase of land. The cost per mile is £3,200, and it is probable that a dividend of 12 per cent. will be earned on the capital. There are few examples of such a profitable undertaking in this country.

ROME, 23rd March, 1891.

EXHIBITION AT MILAN.—An Exhibition devoted to the subjects of hygiene and the education of children will be held in Milan during the month of May next.

STEAM BOILERS.—The Ministry of Agriculture, Industry, and Commerce has recently published some statistics relating to the use of steam boilers in Italy. The returns show that a considerable increase in the number of boilers has taken place during the last few years in the various provinces. In 1889 the total number of steam boilers, excluding those used for locomotion, amounted to 9,983, representing 156,680 h.p., whilst according to the previous returns made in 1876 there were only 4,459 boilers, representing 55,632 h.p. It is thus seen that in the space of twenty-three years the number of boilers has been doubled, and the total amount of horse-power has been nearly trebled. The average power of each boiler in 1876 was 12·48 h.p., whilst in 1889 it was 15·75 h.p. On examining the figures for each separate province, it is seen that Lombardy takes the first place with 2,540 boilers, developing 42,489 h.p.; the province of Venice comes next with 1,571 boilers, developing 20,644 h.p. The province of Emilia has 1,114 boilers, with 13,319 h.p.; Piedmont, 841 boilers, and 17,033 h.p.; Tuscany, 847 boilers, and 10,717 h.p.; Ligury, 601 boilers, and 16,290 h.p.; Sicily, 545 boilers, and 7,130 h.p.; Campania, 349 boilers, and 9,196 h.p.; the Puglie, 364 boilers, and 5,506 h.p.; the province of Lazio (Rome), 337 boilers, and 2,948 h.p. The other provinces have all less than 300 boilers, and the aggregate power of all of them scarcely amounts to 9,406 h.p. On comparing the figures for 1889 with those for 1876, the greatest increase is found in the province of Milan (Lombardy), where the number of boilers has been increased by 992, and the power by 23,075 h.p. Then the province of Genoa (Ligury) shows an increase of 448 boilers, and 13,630 h.p. With the exception of Cagliari, Cuneo, Pavia, and Potenza, where there has been a decrease amounting to a total of 3,800 h.p., all the other provinces have had a larger or smaller part in the total increase.

NEW YORK, 14th March, 1891.

THE UNITED STATES PATENT OFFICE IN 1890.—The number of patents issued and reissued in 1890, as shown by the Commissioner's annual report to Congress, was 26,292, and the number of applications was 41,048. This shows an increase of business over any previous year, amounting in the respective items to 2,059 and 473. The total receipts of the office were $1,340,373·66 and the total expenditures $1,099,297·74, leaving a surplus of $241,074·92. The Patent Office now has to its credit in the United States Treasury $3,872,745·24.

LIGHTING A RAILWAY TUNNEL.—A good deal of satisfaction is expressed at the announcement that the Delaware, Lackawanna, and Western Railroad has decided that the Bergen tunnel shall be lighted by electricity. The work will be carried out by Mr. Paul H. Brangs, the electrician of the railway company

EARNINGS OF RAILWAYS IN THE YEAR 1890.—The gross and net earnings of railways in the United States for the calendar year of 1890, as compared with those of the previous year, are as follows, according to statistics collected by the *Financial Chronicle*:—

Jan. 1 to Dec. 31.	Gross Earnings.		Net Earnings.		
	1890.	1889.	1890.	1889.	Inc.
	$	$	$	$	P.c.
Trunk ...	272,591,793	256,549,164	84,652,117	82,641,038	2·43
Mid. W'n.	49,776,826	46,138,203	17,827,477	17,095,789	4·28
Nth.-Wn.	126,338,046	118,300,471	43,435,274	42,575,280	2·02
Sth.-Wn.	68,767,372	60,814,175	21,595,233	19,840,694	8·84

PHILADELPHIA, 13th March, 1891.

AMALGAMATION OF IRON AND STEEL COMPANIES.—The Lackawanna Coal and Iron Company and the Scranton Steel Company have combined under the title of the Lackawanna Steel and Iron Company. The new company will issue stock to the amount of $3,000,000 to the stockholders of the Lackawanna Company and $750,000 to those of the Scranton Company.—A steel rail combination has been formed, and includes the following companies:—Bethlehem Iron Company, Illinois Steel Company, Penna Steel Company, Edgar Thompson Steel Company, Cambrian Iron Company, and the Lackawanna Steel and Iron Company.

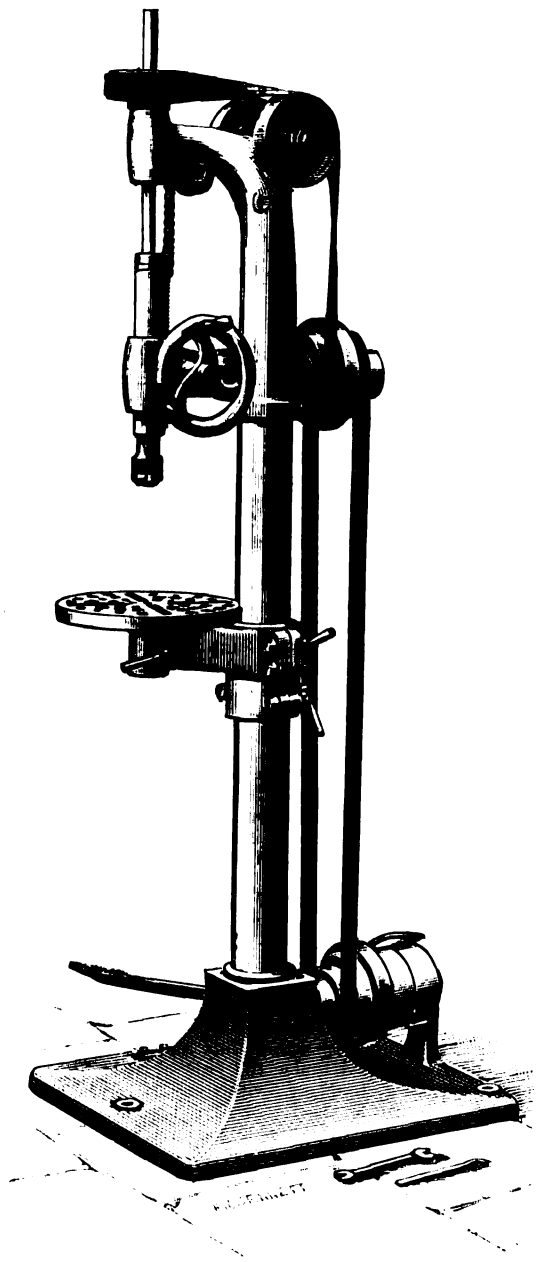
RAILWAY RETURNS.—The annual report of the Pennsylvania Railroad Company for the year ending December 31st, 1890, shows that the gross earnings were $133,521,622; working expenses, $92,003,364; and net earnings, $41,518,257. The net earnings of the main line and branches between Philadelphia and Pittsburgh were $11,030,401, and the dividends paid during the year, at the rate of 5½ per cent., amounted to $6,241,873. The amount transferred to profit and loss account for 1890 was $3,014,441. After deducting extraordinary expenses incurred through the Johnstown floods, there was a balance of $1,949,739. The total amount placed to the credit of profit and loss account on December 31st, 1890, was $22,017,793.—It is now practically settled that the Ohio Valley Railroad will pass into the control of the Chesapeake, Ohio, and South-Western Railroad. This acquisition virtually gives through connections and entrance into Chicago to the latter company.—A company to provide Kansas City, Mo., with a belt line and terminal facilities has been organised under the title of the Kansas City Circular Railway Company, with a capital of $1,500,000.

INTERCONTINENTAL RAILWAY.—The Intercontinental Railway Commission has arranged the preliminaries for making a survey of the proposed railroad. Mr. William F. Shunk, of Pittsburgh, was selected as organising engineer, and will have general charge of the work, for which his services in carrying out the line of the Pennsylvania Railroad over the Alleghany mountain particularly fit him. There will be three surveying parties, including the military party already assigned to the Central American States, and they will work north and south from a centre point in Colombia. It is expected that it will take eighteen months to complete the surveys with the present staff, which is limited, owing to the comparatively small amount of funds at the disposal of the Commission.

THE EDGAR THOMPSON STEEL COMPANY.—The shutting down of the Edgar Thompson Steel Company for repairs several weeks ago has thrown 2,000 men out of employment. The works will not resume operations for several weeks.

THE STRIKE AT MONONGAHELA VALLEY.—The strike of the Monongahela Valley coal miners has ended in a victory for the men. The demand for an increase of ½c. per bushel was acceded to. The strike, which continued since January 1st, has affected 25,000 people. The number of miners idle since January 1st was 10,000.

FLOODS IN ARIZONA.—The damage done by the floods near Clifton, Azizona, will amount to $100,000. The San Francisco River has shifted its channel, leaving several bridges over dry land.



NAVAL.—The cruisers "Philadelphia" and "San Francisco" have been formally accepted by the Secretary of the Navy. The former was built by Messrs. Cramp, and the latter in San Francisco.

PROPOSED DRY DOCK.—The committee appointed to select a site for a dry dock on the Gulf of Mexico recommends the South Pass of the Mississippi, as affording the only entrance 26ft. deep to a harbour far enough from the sea to be safe from gun fire. The property selected belongs partly to the Government the remainder being available at about $150,000.

QUICK-RUNNING DRILLING MACHINE.

The accompanying illustration represents a quick-running drilling machine, which is specially designed for light work, such as that likely to be met with in electrical engineers' shops, where small holes are required to be drilled in large numbers with accuracy and despatch. The machine, which is made by the Britannia Company, of Colchester, has a counterbalanced steel spindle working through the driving pulley and sleeve,

and is adjustable by a hand feed through a distance of 6in. It will drill a hole ⅝in., and has its spindle nose fitted with a convenient scroll chuck. No toothed gearing is used, the revolving parts being driven by flat belts, while the starting appliance consists of a treadle lever, by means of which the driving belt may be transferred from the fast to the loose pulley, or *vice versâ*. The machine stands 6ft. 6in. in height, and weighs about 5¼ cwt. It is excellently finished, and of the best material.

SOME DETAILS IN MARINE ENGINEERING.*

In laying a description of the following details before so important an Institution as that of the Naval Architects, the writer feels that some apology is needed, as he has no new theory to evolve, no new discovery to lay bare, and little or nothing to describe that is new in any way. In the conviction, however, that the difference between economical and uneconomical engines, between long-lived and short-lived boilers, between satisfactory and unsatisfactory engineering, lies very commonly in small differences of detail rather than in any grand difference of principle, he has thought that the discussion of a short paper regarding a few details to which he attaches importance might be of general interest.

* Paper read by Mr. Thomas Mudd before the Institution of Naval Architects on the 20th inst.

Boilers.—The ordinary method of building marine boilers is to flange the end plates and fit these into plain cylindrical shells. The end plates in boilers of ordinary size cannot be made in one piece, and hence the flange is not a plain continuous flange, but is broken up where it passes the cross joints of the plates, the plates being thinned at the joint so as to imitate as far as possible a plain, continuous flange. The flange, however, meets with another difficulty where it passes the inside butt strap of the longitudinal shell-joint, and here it is common to thin down the inside strap plate to a wedge shape, and cut out from the flange of the end plate a similar wedge piece, so as to minimise that obstruction. It should be noted in passing that it is practically impossible in boiler work to make the wedge-shaped gutter in the flange of the end plate a steam-tight fit on the wedge of the strap plate, and leakage at the ends of these butt straps is of the commonest occurrence, even where great care has been bestowed to avoid it. Another source of leakage at the ends of the butt joints is due to there being always presented to the atmosphere an open joint where the butt occurs, equal to the thickness of the plate, the tightness of which depends upon the tightness of the inside strap and on external caulking. The writer believes that both boiler builders and boiler users will sympathise with his remark when he states that nothing is more difficult or more tedious in boiler building than to get the ends of these butt-strap joints quite satisfactory.

Another difficulty incident to this ordinary method of making boiler ends is that the rivets securing the end of the boiler shell are placed radially to the boiler, and round the bottom they are practically beneath the boiler, where they are very liable to severe corrosion. It is obvious that when these lower rivets in the front end seam become corroded, renewal is very difficult, and sometimes quite impossible, owing to the proximity of the furnace tubes. In putting the boiler together, also, it is obvious that the shell ring and the end plate flange should be so exactly of one size as would be represented by a turned and bored driving fit; for where the end plate flange is a shade too small for the shell ring when the shell-plate joints are hard butted together, there is obliged to be a pucker somewhere when riveted up. Such an end joint is certain to leak, and it has the aggravating characteristic that, when the leak is caulked, it simply shifts along ahead of the caulker, leading him on farther and farther, like a "Will o' the Wisp." If, on the other hand, the end plate is rather too large, the shell butt joint remains sufficiently open to make it almost impossible to prevent leakage through it. In endeavouring to sail between these two rocks, it is common practice to leave one cross joint of the end plate loose until the flange joint is riveted to the shell. And whilst this is, doubtless, the best way to proceed, it is clear that, with the end plate keyed on the inside butt strap, as above described, it is not easy to arrive at perfection even by that expedient.

To speak generally, therefore, this common method of building marine boilers by flanging the boiler end plate involves difficulties by its very principle, incurs great and tedious labour to secure anything approaching good work, and when all has been done that the highest boiler-making skill can do, the result is not entirely satisfactory. When boilers were built of iron, one or two prominent makers, who recognised the above facts and difficulties, set about overcoming them by the simple expedient of putting the flange on the shell plate instead of on the end plate. At first sight this might not appear to be any gain, but it is quite otherwise when the possibilities which this change brought with it are fully thought out. It has been suggested that, instead of flanging the shell, the ends of the seams of the end plates might be welded, and the end plate flanged in the usual way, so as to make one continuous flange all round. This is certainly one step in advance, and it is a method that is carried out by some of the best makers. Whilst, however, this method obviates all the trouble at the ends of the cross seams of the end plate, it does not affect in the least the perhaps greater troubles at the ends of the longitudinal butt joints, and it prevents any advantage being taken of the slight adjustment that can be got by leaving a cross seam of the end plate loose, as above described. The difficulty, therefore, of making the shell ring precisely fit the flanged end plate still remains, and the danger of the shell being a shade too large, causing pucker and local stress in the plate, or of its being a shade too small, causing leakage troubles at the butt joints, are not by this method likely to be removed. When, however, the shell ring itself is to be flanged, there is nothing whatever to prevent its first being welded at the butt joints for a short distance, say 18in., so that the flange subsequently made is one continuous ring flange, without break or change at any part. The end plate then becomes a mere flat disc, without any flange whatever, and, as the ends of its cross seams can also be welded into one thickness, it becomes at once apparent that every difficulty to which we have referred vanishes completely. For since the shell ring is welded at the flange, the difficulty with butt straps interfering with the flanged part ceases, because both the inside and outside butt straps can be stopped short just at the place where the turn of the flange begins, having then well covered the commencement of the weld.

In the next place, the trouble from thinned corners on the end plate ceases, because the end plate is welded up at the ends of its seams into one complete flat disc. Further, there is no such thing to do as fitting one part into another, there is no such thing to fear as pucker or local stressing of the shell, for the end plate plies up naturally to its flange in the simplest possible way, without any fitting whatever. Besides all this, from the constructive point of view there remains the fact that the rivets in this end seam are by this method placed longitudinally in the boiler, and whilst the seam near the bottom of the front is not so liable to corrosion as by the more common method of building, there is this great advantage, that when the rivets do corrode they can be quite easily renewed, because the furnace tubes do not interfere with getting them in.

When mild steel was introduced in boiler building the question arose as to whether the material would bear this treatment as satisfactorily as the iron had previously done. The writer was of opinion that if the steel were of such a character as to be fit for boiler building at all, it ought to be able to bear, and would bear, this simple treatment. Indeed it is now matter of the commonest knowledge that good mild steel will bear enormously more punishment than iron would. Feeling confident in this belief, and knowing from previous experience the very great advantages both to the constructor and the user of this method, the writer commenced in 1884 to build steel boilers on this plan, having first provided special plant for satisfactorily dealing with them, and to the present time more than 200 high-pressure boilers have been so constructed without the slightest hitch or difficulty, or failure of any kind arising in any one of them. There are various points in this method upon which difference of opinion might be expected, at all events amongst those who have not seen a boiler so constructed, as for instance the following:—

The Weld.—Can boiler steel be satisfactorily welded? Is any test applied on the individual weld? Has the weld to bear tension when the boiler is at work? In answering these, experience over the many hundreds of shell welds that have been made in 200 steel boilers shows that with ordinary care an ordinarily good workman can make a sound weld by using a best Yorkshire iron glut, and we have never had a single weld show leakage. Perhaps the very best test of all that could be applied under the circumstances is applied to each individual weld—viz., the weld being made before the plate is flanged, has to stand the subsequent flanging in the hydraulic press, and it seems certain that if it were a mere surface weld it would divide when the disturbance caused by the flanger came upon it. With regard to tensional stresses, the writer wishes to be very emphatic in disclaiming any application of the tensional stresses of the boiler shell to the weld. The butt straps extend to the very edge of the curve of the flange, and the flange itself represents an extra amount of shell material given in beyond what is required to sustain the stresses due to the length of the boiler. Even this flange is also in the condition of having a strap passing over the weld, for the end plate forms a good practical strap to the flange. To put the matter another way, the flange of the shell forms a kind of strengthening bead at the edge of the plate, adding considerably to its strength, and greatly reducing liability to rupture from the edge. The weld, therefore, is only exposed from beneath the straps at the curve of the flange, where from the form of the plate it is very strong, and where practically it has nothing to do but secure steam tightness. An eminent engineer, whose views on practical matters are greatly valued by this Institution and by the profession at large, remarked, in his usual original way, on seeing one of these boilers:—"Suppose you saw-cut the weld through at the part where it is exposed, what would happen? The boiler would not burst, for the stresses are securely carried by the straps. All that could happen would be leakage."

The Effect of Flanging.—Will heavy boiler steel satisfactorily stand flanging to a right angle? Does the necessary local heating seriously injure the plate? Are the plates annealed after flanging? The writer is of opinion that if boiler steel cannot be flanged at right angles with a fairly large radius in the corner when red hot without injury, it is not fit to build boilers with at all; and since he has now had flanged about 1,000 large thick shell plates without returning to the makers more than two plates which showed slight surface tearings on being flanged, he has no hesitation in saying that ordinarily good mild boiler steel will stand this flanging in a perfectly satisfactory manner. With regard to local heating, there is probably a great difference in effect on the plate between heating along the edge and heating locally towards the middle of the plate. In any case the writer again appeals to the large experience he has now had of this method as the proof that no damage accrues to the plate. It does, however, seem to be a wise precaution to anneal the plate after the welding and flanging is completed, and before any riveting is done, and therefore these shell rings are lowered flange downwards into an annular furnace, heated to a red heat, and allowed to remain to cool down with the furnace.

The Rivets and the End Seam.—Rivets are generally put in shearing stress. The rivets in this end flange are exposed to tensional stress. Is that detrimental, and does the tendency of the pressure on the ends of the boiler to tear away the end plate from its flange result in springing the joint and causing leakage? The back ends of single-ended boilers are riveted by a large vertical hydraulic riveter, forming a snap head both inside and outside. The front end seam being the closing seam of the boiler, is riveted by hand, the rivets having snap heads inside and deep countersinks almost through the plate on the outside. Both ends have double-riveted joints, the rivets being placed in zig-zag. Mild steel is so excellent a material for carrying tensional stresses that it is difficult to find a reason for preferring rivets acting in shear. Indeed, the question only seems to be suggested by the fact that in ordinary practice rivets are generally in shear. The tension also on these rivets is extremely light, as will be observed by noticing the distance between the centre of the seam and the nearest mainstays and tube stays and furnaces. Referring, again, to that sure guide—experience—the writer has to say that these end seams give practically no trouble whatever, and are infinitely superior in their capability to remain all the year round quite free from leakage to boiler ends made on the older plan. The writer's latest development is in connection with boilers of large diameter where the front end plate consists of three plates—viz., a top plate taking the main stays, a middle or tube plate, and a lower or furnace front plate. In these cases the top plate and the bottom plate are set to their proper distance apart, and permanently connected together at the corners by welding to them a narrow, curved strip of plate of equal thickness, so as to make the edge continuous all round, just as it would be if the end plate were in one piece. Then the gap in the middle is filled up by laying the tube plate over these, upon which it sits quite naturally without any bending, joggling, or thinning whatever. The end seam rivets in this case pass through three thicknesses of plate, where they attach the tube plate to the shell flange. This has proved eminently satisfactory, and leaves a flat surface on which to build the smoke-box.

Summing up this method generally, it may be remarked that there are no thinned corners in any of the plates or straps, there is no joggling of one plate over the edge of another, there is no relying for good work upon exceptional skill and almost impossible care, as one part plies naturally to another, with the result that at the hydraulic test of twice the working pressure it is a rare thing to see the slightest leak from these boilers, and they give practically no trouble whatever in use at sea, to the great comfort of those in charge and the great saving of those who own them.

Boring Stern Frames.—If a line of shafting in a ship is to run well it is necessary that it should lie naturally in its bearings, without binding hard on any special side; or, in other words, that one shaft should lead perfectly fair with another throughout the whole length. As stern tubes require to be water-tight where they pass through the stern frame, it is usual to make at that part no flexible joint, but a rigid one, either by a taper or otherwise. It thus becomes necessary for the bore of

Digitized by Google

the stern frame to be accurately done, as that bore determines the direction in which the tube will lie, thus also determining a fixed and rigid lead for the first after-length of shafting. A little relief to inaccuracy there certainly is, inasmuch as the engines themselves in the engine-room may generally be moved from side to side, or up and down, through a small distance to accommodate any slight deviation from absolute accuracy in lead. But when it is remembered that an inch, or even two, at the engine-room represents a very faint amount in the length of the bore of the stern frame, the accuracy that is necessary in placing the boring bar, if there is to be no spring upon the shafting, becomes apparent.

Various methods are adopted for lining off a vessel with a view to determining the position and direction of the axis of the boring bar for boring the frame, some of which are more or less primitive and defective. When getting up new plant for a new marine engine building establishment in 1883–4, it occurred to the writer to have a special boring plant, devised in such a way that the bar should be hollow, having a clear opening from end to end, with a part of the opening at the after end truly bored in line with the axis of the bar, and of such a diameter as to receive a carefully constructed telescope, which could be easily slid into it. This telescope is provided with cross hairs and proper focal adjustments, so that the horizontal and vertical marks indicating the intended position of the centre of the crank shaft marked on a board erected on the engine seating can be easily seen from the distance of the stern frame of the ship. Besides the great degree of accuracy incident to this method, it has the advantage of being simple and direct, for the bar is in position when the sight is taken, and is simply adjusted up and down, or from side to side, until the user of the telescope is satisfied with the sight: it is then only necessary to make all fast and commence work. A hundred steamers have been sighted and bored with the use of this telescope during the past six years with highly satisfactory results. The writer is not aware whether this method is in use at any other establishment. It is certainly not in common use on the North-East Coast, though from its simplicity and accuracy it would seem to be well deserving of adoption.

(To be continued.)

SHIPBUILDING NOTES.

On the 2nd inst. the s.s. "Sophia Couppa," built by Messrs. Craig, Taylor, & Co., of Stockton-on-Tees, to the order of Messrs. Vagliano Bros., of London, was taken out to sea for her trial trip, which proved very satisfactory. The dimensions of the vessel are:—292ft. by 37ft. by 20ft. 3in. She is built on the web-frame principle, and has double bottom for water ballast for about 600 tons. Her engines, on the triple-expansion three-crank system, by Messrs. Blair & Co., Limited, of Stockton, have cylinder diameters of 21in., 35in., 57in., by 39in. stroke, and two large steel boilers give 160lb. pressure. During the trial a speed of over 9¼ knots was obtained against a severe head wind.

On the 7th inst. Messrs. Short Bros. launched a screw steamer, built to the order of Mr. John Sinclair, West Hartlepool. Her principal dimensions are—Length between perpendiculars, 180ft.; breadth, 29ft.; depth, 12ft.; and she has been specially designed to carry a large cargo on a light draught. The engines are by Messrs W. Allen & Co., Scotia Engine Works, of 15½in., 25in., and 41in. cylinders, and 27in. stroke, with steel multitubular boiler of 160lb. working pressure. The vessel is constructed to the highest class in Lloyd's Registry for steel, and has a long raised quarter-deck, bridge amidships over engines and boiler, and top-gallant forecastle. She has three very large hatchways, two steam winches, and donkey boiler, steam steering gear, &c., and is fitted with water ballast in the fore and after holds. Both peaks are fitted as trimming tanks. The engine skylight is fitted with six of Mason's patent skylights, each containing two 9in. lights. The saloon is similarly fitted with Mason's side-lights. The hull, engines, and boilers have been built under the personal supervision of Mr. George N. Arnison, Jun., of Sunderland.

On the 7th inst. the fine steel screw steamer "Buckingham" had her trial trip in the bay off Hartlepool. The vessel has been built by Messrs. Wm. Gray & Co., Limited, to the order of Mr. Christopher Furness, for Messrs. Raeburn & Verel, of Glasgow. Her dimensions are:—Length over all, 324ft.; breadth, 40ft. 6in.; depth, 23ft. 8¼in.; and her deadweight capacity is about 4,350 tons. The engines, which are of the triple-expansion type, have been supplied by the Central Marine Engine Works of William Gray & Co., Limited, and are of the size designated by the makers, 1,300 i.h.p. Steam is supplied by two large steam boilers working at a pressure of 160lb. per square inch. A speed of 12 knots per hour was obtained.

On the 9th inst. the s.s. "Loo Sok," built by the Fairfield Shipbuilding and Engineering Company, Limited, was launched from their yard at Govan. The vessel has been built to the order of the Scottish Oriental Steamship Company. The "Loo Sok" is intended for Chinese coasting service, and has been built to the requirements of the Bureau Veritas and the Board of Trade. The dimensions are:—Tonnage, 1,650; length, 270ft.; breadth, 36ft. 9in.; depth, 22ft. 9in. There is a double cellular bottom, a straight stem and elliptical stern, and a double turtle-back. The engines are of triple-expansion type, with cylinders 22in., 36in., and 57in. diameter respectively.

On the 10th inst. Messrs. Richardson, Duck, & Co. launched from their building yard at South Stockton a steel screw steamer, "Crown of England," of the following dimensions, viz.:—Length over all, 307ft. 4in.; breadth, extreme, 40ft.; depth, moulded, 21ft. 8¼in. This vessel, which has been built for the Crown Steamship Company, Limited, Belfast (Messrs. W. Gibson & Co., managers), is classed 100 A1 at Lloyd's. She has a cellular bottom fore and aft for water ballast, a short poop, long raised quarter-deck, and partial awning deck extending from after end of engine-room to stem. The engines, by Messrs. Blair & Co., Limited, of Stockton, are triple expansion with cylinders 22in., 36in., and 59in., by 39in. stroke.

On the 12th inst. the "Indefatigable," one of the new second-class protected cruisers, was launched by the London and Glasgow Engineering and Iron Shipbuilding Company, Govan. The firm are building three of these cruisers, of which this is the first. The others are to be called the "Iphigenia" and the "Intrepid." The dimensions are:—Length, 300ft.; breadth, 43ft. 8in.; depth, moulded, 22ft. 9in. The displacement is 3,600 tons. The engines are of 9,000 i.h.p., and are triple-expansion surface-condensing. The cylinders are inverted, and have diameters 33½in., 49in., and 74in. The stroke is 39in. The hull is sheathed with teak, and is copper-covered to about 3ft. above the load-line. The stern-post, stem, ram, rudder, propeller, and shaft tube brackets are of phosphor-bronze. It is expected that a speed will be attained of 20 knots per hour. The armament will consist of two 6in. breech-loading central pivot guns, six 4·7in. quick-firing guns, eight 6-pounder Hotchkiss guns, four 45in. five-barrelled Nordenfeldt guns, and four torpedo tubes.

Notices of Meetings.

THIS WEEK.

Manchester Association of Engineers.—Saturday, March 28th, at 7 p.m. Paper to be read: "Steam Engine Governors," by Mr. C. F. Budenberg.

PRICES CURRENT, 24th March, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: No change of importance has taken place during the past week, and prices are steadily maintained. Stocks are reported to have decreased about 2,400 tons during the first fortnight in March, and Chili bars have advanced in value, being quoted to-day £52 12s. 6d. cash, with three months' prices 5s. higher. Manufactured unchanged at £65, "strong."

Tin: Steady, with prices slightly lower.

Lead: Rather firmer, but with small demand.

Spelter was a shade easier last week, on a rumour gaining currency that the smelters' arrangements for regulating the production had been ended. This rumour had, however, reference only to a minor agreement in Silesia for manufactured zinc. The general spelter arrangement is firmly upheld, and prices will be maintained accordingly.

PIG IRON—BRAND "CARRON."

Present prices of "Carron" Pig Iron are as follow:—

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Since our last there has been a very strong demand for all qualities of sulphur, and prices have advanced some 20s. to 30s. per ton. Sulphate of ammonia also has attracted many buyers, and a large business has been done at considerably advanced figures. With these exceptions the markets are flat. Sulphate of copper has lost ground, and there is quite a want of confidence in the future. Lime salts are more freely offered at lower prices. Green copperas is more plentiful. Yellow prussiate is steady, though quieter.

HOME INDUSTRIES.

LONDON, 26th March, 1891.

The Money Market.—The key to the condition of the money market was supplied in the allotment of a million and a half of Treasury Bills on the 23rd inst. Discount rates had hardened a trifle towards the end of last week, owing to considerable withdrawals of gold for the River Plate, but when Treasury three months' paper was placed at a price equivalent to a discount rate of 2⅛ per cent., an easier feeling speedily became apparent. Although the Stock Exchange settlement gave employment to a fair amount, call money has been easily obtainable. A week which begins with a settlement and ends with holidays is never productive of much interest on the Stock Exchange, and this has been no exception. The tendency has been fairly firm, but business has been on a small scale. The most noteworthy feature was the improvement in most home railways, owing to the scarcity of stock revealed at the settlement. American railways have been better, notably the favourite investment stocks. Foreign securities have kept steady. Copper shares have advanced, but in mining and miscellaneous shares generally there has been no feature of note.

Royal Meteorological Society.—The usual monthly meeting of this Society was held on the 18th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster, S.W., Dr. C. T. Williams, Vice-President, in the chair. Mr. G. J. Symons, F.R.S., read a paper on the "History of Rain Gauges." It appears that Sir Christopher Wren, in 1663, designed not only the first rain gauge, but also the first recording gauge, although the instrument was not constructed till 1670. The earliest known records of rainfall were made at the following places:—Paris, 1668; Townley, in Lancashire, 1677; Zurich, 1708; and Londonderry, 1711. Mr. Symons gave a very full account of the various patterns of rain gauges, and in most instances pointed out the merits or defects of each. Mr. A. W. Clayden, M.A., showed on the screen a number of interesting transparencies of photographs of clouds, lighting flashes, and other meteorological phenomena. The meeting was afterwards adjourned in order to allow the Fellows to inspect the exhibition of rain gauges, evaporation gauges, and new instruments, which had been arranged in the rooms of the Institution.

Royal Institution.—The following are the lecture arrangements after Easter:—Mr. J. Scott Keltie, three lectures on the Geography of Africa, with special reference to the Exploration, Commercial Development, and Political Partition of the Continent; Dr. E. E. Klein, three lectures on Bacteria: their Nature and Functions (the Tyndall Lectures); Mr. William Archer, four lectures on Four Stages of Stage History (the Betterton, the Cibber, the Garrick, and the Kemble Periods); Professor Dewar, six lectures on Recent Spectroscopic Investigations; Dr. A. C. Mackenzie, four lectures on the Orchestra considered in connection with the Development of the Overture; Professor Sylvanus P. Thompson, four lectures on the Dynamo; Mr. H. Graham Harris, three lectures on the Artificial Production of Cold; Professor A. H. Church, three lectures on the Scientific Study of Decorative Colour. The Friday evening meetings will be resumed on April 10th, when a discourse will be given by Sir William Thomson, on Electric and Magnetic Screening; succeeding discourses will probably be given by Professor A. W. Rücker, the Rev. Canon Ainger, Mr. J. E. Harting, Professor W. Ramsay, Professor G. D. Liveing, Professor J. A. Ewing, Dr. David Gill, Professor Harold Dixon, and other gentlemen.

Miners' Electric Safety Lamps.—The Council of the Federated Institution of Mining Engineers are desirous of receiving exhibits of miners' electric safety lamps, to be shown at the annual meeting of the Institution, which is to be held in London on May 27th and 28th next. Intending exhibitors are desired to communicate with, or send their exhibits to, the secretary, Mr. M. Walton Brown, Newcastle-on-Tyne.

Appointment.—Mr. W. S. Child, A.M.Inst.C.E., for many years chief assistant to the late firm of Messrs. Kinipple & Morris, of Westminster, has been appointed engineer to the Port Aden Harbour Trust.

St. Pancras Electrical Exhibition.—Owing to the great success of this Exhibition, which is now being held at the St. Pancras Vestry Hall, it has been decided to allow it to remain open until 1st April.

United Asbestos Company, Limited.—At the annual meeting of the shareholders of this company, held recently, a dividend of 10 per cent. was declared and paid upon the preference shares, and the balance of profit for the year, equal to a little over 5 per cent. on the ordinary shares, was carried forward.

MANCHESTER, 26th March, 1891.

The Ship Canal.—A meeting of citizens of Manchester was held on the 23rd inst. to consider the proposals of the Corporation to contribute a loan in aid of the works connected with the above company. There was a large attendance, and a resolution approving of the action of the Council was passed almost unanimously.

The Reduction of Hours Movement.—The Iron Trade Employers' Association, after considering the joint circular issued by the various trade unions affected, asking for a reduction of hours to 53 per week, have replied, stating that under all the circumstances they cannot agree to the request. It now remains to be seen whether any attempt will be made to enforce the adoption of this working week. In some respects the opportunity is a favourable one, as, despite the undoubted slackening of demand, the majority of the engineering concerns are full of work and have enough to employ them throughout the year.

Arts and Crafts Exhibition.—An Exhibition has been opened in the City Art Gallery of various arts and crafts practised in the neighbourhood. Specimens of art work from South Kensington Museum form a great part of the Exhibition, which, although interesting, is in some respects disappointing. One of the rules of the Exhibition provided that although business firms might send exhibits the name of the actual craftsman must be supplied, and this has been done. A first sight of the exhibits enables their scope to be understood, but generally the result is not very satisfactory, only a few of the cases being worthy of separate notice. It is somewhat noticeable that although there are large numbers of designs for printed cotton fabrics those for woven fabrics are much fewer in number. The most promising work is seen in the cases from the weaving department of the Technical School, Sloyd work from the Deaf and Dumb School, in some art metal work of good quality, and in one or two cases of embroidery. The Exhibition is to remain open till June.

The Linen and Jute Trades.—There has been a better feeling during the past week, but the approach of Easter so soon after the depressing effects of recent unfavourable weather had been dispelled rendered it impossible to altogether compensate for the losses incurred. Distribution has undoubtedly proceeded rapidly during the past fortnight, and the demand for stocks in the hands of merchants has been considerable. Scotch agencies here are now engaged in stocktaking, which operation will be completed by the end of March. There is a steady demand for the fine Hessians used for packing by the home trade firms, and this is a sure sign that the general dry goods trade is satisfactory. The demand for the limited number of flax yarns consumed in this district is fair. Quotations for foreign "spins" are very firm, and it is evident that the position on the Continent has been strengthened considerably of late, as there is no disposition on the part of sellers to meet buyers except at full rates. The shipping trade keeps dull, and Chilian prospects become worse, private telegrams from Iquique received recently in Manchester saying that the conflict may eventually be extended to the sea, where the Parliamentary party is at present supreme. For Canadian and Australian account there is not much doing.

English versus Continental Prints.—Inquiries made this week in the print departments of the leading wholesale houses reveal the pleasing fact that the leading Lancashire and Cheshire printers have now attained such excellence in the processes they employ that even in goods of the highest class, which have been usually imported from France, they can beat the best Continental manufacturers and sell much more cheaply. Large merchants find that all their requirements can now be satisfied at home, and that the supremacy of "French prints" is a thing of the past.

GLASGOW, 26th March, 1891.

Railway Operations.—The execution of the contract on the eastern section of the Caledonian Central (Underground) Railway at Bridgeton has been stopped in consequence of an interdict having been granted by the Sheriff Substitute on the application of the Corporation of Glasgow. The ground of the application was that no definite arrangements had been made regarding the diversion of the sewage. The work of piling and underpinning has therefore been entirely suspended.—The Ayrshire and Wigtonshire Railway, which has been worked by the Glasgow and South-Western Railway, and which has been a source of loss both to the original promoters and to the working company, was the subject of a Bill, brought forward in the interests of the shareholders and of the Caledonian Railway, for the purpose of sanctioning a perpetual lease or sale of the line. The Bill was opposed by the Glasgow and South-Western Railway, and, after evidence had been taken, the preamble was found not proved, and the Bill was therefore thrown out.

The North British Railway Company.—The circular issued by the company last week, containing a statement of the concessions the directors are prepared to make, was discussed by the men at their meetings in different parts of the country on the 22nd inst. The general feeling seemed to be one of dissatisfaction with the extent of the changes. The chief question, which is that of excessive overtime, is represented by the men as being practically untouched. This is, no doubt, an exaggerated view; but the continued existence of unallayed discontent is a serious matter for the railway, which has already suffered so severely from a strike. Any trifling with the matter must inevitably result in trouble. The company has been compelled to concede so much that the men feel encouraged to show a bold front and to demand more. If the directors have re-organised the service on a sound basis no one can blame them if they adhere firmly to the terms of their new regulations; but if they have any further modifications to make, it were well that these should be made now, since unquestionably further trouble is brewing. It is not unlikely, however, that the men will be pacified by the prospect of the legislation that is regarded as certain to be the outcome of the Select Committee now inquiring into the hours of railway servants.

(From our own Correspondents.)

LIVERPOOL, 25th March, 1891.

The Mersey Railway.—As a result of the protests made at many of the recent meetings of the shareholders of this company against the meeting being held in London, the last half-yearly meeting was held in Liverpool. In the absence of the chairman—Mr. Francis Fox—through illness, the chair was taken by Mr. J. T. Balfour, M.P. The report states that the receipts have increased from £28,175 in 1889 to £29,974 last half year; there had, however, been a slight increase in the working expenses, owing to the increased price of coal. The cost of pumping, ventilating, and working the lifts was 22·82 per cent. of the expenditure, the working expenses, exclusive of the exceptional charges, being 58·04 per cent. The extension to Rock Ferry is nearly completed, and will form the connection with the Great Western and the London and North-Western Railways. The extension to Bold Street, Liverpool, will be opened during the summer. As regards the financial condition of the company, the receivers and managers are now in a position to apply to the Court to make a payment on account to the debenture holders.

The Cunard Company.—The annual report of this company states that the profits for the year, including £4,988 brought forward from 1889, amount to £246,600, and, after deducting income-tax and providing £125,840 for depreciation of ships and property and £43,143 for insurance, there is left £72,838. Out of this the directors propose to pay £64,000 as dividend, equal to 4 per cent. per annum, and to carry forward £8,838 to the credit of profit and loss in 1891. The price of coal, increased wages, and strikes have involved the company in considerable additional expenditure.

LEEDS, 25th March, 1891.

The Iron and Steel Trades.—The amount of business in the iron and steel industries of this district towards the end of the first quarter is less than was expected at the opening of the year. There is quietness all round, with unremunerative prices, particularly in the finished iron trade, and the holding of the quarterly meetings is awaited with much interest. In the engineering branch there is less activity than was the case a few weeks since, and some of the largest establishments have felt the effects of a quiet market and the disinclination of people to place orders. There has during the year been a falling off in the orders from shipbuilders. A large amount of work for railways, however, is in hand, both in engineering shops and at rolling mills.

The Coal Trade.—Cold weather has in the last fortnight rather stimulated the demand for house coal. There is a fair trade in steam and other classes of coal. Prices remain unchanged.

The Late Mr. David Greig.—Mr. David Greig, of the firm of Messrs. John Fowler & Co., steam plough and locomotive works, Leeds, died on the 20th inst. Mr. Greig had, either as manager or partner, been identified with the firm of Messrs. Fowler & Co. for many years.

SHEFFIELD, 25th March, 1891.

The Iron and Steel Trades.—The iron and steel trades continue active in all their branches. The demand for railway material shows no signs of falling off, and the orders recently given out by the home railways will keep works well employed. Prices continue steady at the following rates:—Tyres, £10 to £11; axles, £10 to £12; springs, according to the amount of skilled labour required, from £11 to £15. The Admiralty have issued tender forms for 12,500 tons of ship plates, mild steel, and about 4,000 tons of angles and other sections used in shipbuilding and general engineering work, and a part of the order will no doubt be placed in this district. The English colonies are just now our best customers, as they are buying rolling stock and bridge material in large quantities. The Leeds engineering firms are also good customers for steel castings and forgings of all kinds.

Coal and Coke.—The demand for coal and coke continues very firm, and prices are unchanged. Prices at the pit bank do not vary much, as the yearly railway and gas contracts keep the collieries fully employed.

Local Trades.—In the specially local trades there is a fair amount of business. File manufacturers suffer from the competition of Continental firms, particularly in the light descriptions. This might have been expected, as the French and German firms have bought largely of the best file-cutting machines made in this district. Edge tool makers are well employed, especially on the best class of work. Makers of sheep-shearing appliances are very busy both on the home and export account. Silversmiths and electro-plate workers are working full time, and a large portion of their products is for the export trade. Messrs. Mappin & Webb have recently erected a powerful engine to drive the numerous machines employed on this class of work.

NORTH STAFFORDSHIRE, 25th March, 1891.

The Iron Trade.—The downward tendency in prices is very marked, and causes much anxiety amongst makers. Owing to the want of orders the forges and mills in this district are working on short time, and there appears little

Digitized by Google

likelihood of any immediate revival of demand. Bar iron is quoted about £6 to £6 5s. delivered in Liverpool, and forge pig iron from 42s. to 45s. at local works, according to quality.

GENERAL.—The first ordinary general meeting of the Shelton Iron, Steel, and Coal Company, Limited, was held in London on the 20th inst., when, in the absence of the Chairman, Earl Granville, through illness, Mr. Stuart Rendal, M.P., presided. The statement of accounts for 1890 showed a net profit of £33,920. A dividend at the rate of 7 per cent. on the preference shares was declared, and a balance of £12,539 was carried forward.

ALUMINIUM-BRONZE. — Cowles' aluminium-bronze continues to make headway, and as the price is now slightly below manganese-bronze it will probably supplant that material for screw propellers in high speed vessels. It is also being largely adopted for hydraulic and other engineering purposes, and for firing tubes for gas engines.

BIRMINGHAM, 25th March, 1891.

GENERAL TRADE.—The approach of the Easter holidays just at the close of the quarter seems to give an impetus to business generally. The makers of stamped forgings are particularly busy, as also are their good customers, the cycle makers. The perambulator builders, too, are busy. Makers of shovels, spades, axes, hoes, billhooks, and general garden tools are full of pressing orders, and the light ironfounding and brassfounding concerns are well employed. There is a great demand in the bedstead trade, and the manufacture of fireproof safes, which many of the bedstead makers combine with their business, is brisk. Rivet makers are unusually busy, especially those making boiler rivets and the larger sizes generally. Chain makers in the Old Hill district are well employed, but there is not much prospect of a continued demand. The New British Iron Company, who have large contracts with the Admiralty for cables, are well advanced with the work, and have built extensive testing machinery for proving these cables. The nail manufacturers employing hand labour view with alarm the proposals made by Lord Dunraven to limit to ¼in. the size of iron which women shall work, and to make it unlawful for women to work at chain or nail-making until they are sixteen years of age. They say that if male has to be substituted for female labour they will not be able to compete with German makers. The workmen are opposed to the views of the masters in the matter.

LEICESTER, 25th March, 1891.

WOOL SPINNING AND YARN TRADES.—Business in the local wool market is quiet, but quotations are very firm. Deep stapled fleeces of good average quality realise 22s. 6d. to 23s. 6d. per tod; superior lots, 24s. to 25s. per tod; choice lots, including large proportion of Shropshire, 25s. 6d. to 27s. per tod. Users buy very cautiously, and for present wants only. Spinners are not very well employed generally. It is very difficult to obtain prices which give a fair margin of profit, and hence the acceptance of new business is not large.

HOSIERY TRADE.—In the fancy department there is an excess of activity, and some good orders are already placed; the prospects of this branch are cheerful. The Cashmere hose department is very quiet just now, and so also is the heavy woollen branch of the trade. There is a very fair demand for fine natural wool underwear, which has become an important factor in the trade here now.

BOOT AND SHOE TRADE.—The output is more satisfactory, but the trade of the year so far is much below last year, and, in fact, it has scarcely reached the average. Leather merchants are doing a larger business, but users operate very carefully. The market is firm, and shows no tendency to a reduction of prices.

SWANSEA, 25th March, 1891.

THE RHONDDA AND SWANSEA BAY RAILWAY.—Great disappointment is felt locally at the decision of the Lords' Committee that the preamble of the Bill before Parliament for powers to make a line from Port Talbot to Swansea has only been proved as regards the portions of the line between Carnarvon and Briton Ferry. The Great Western Railway Company are, of course, the great opponents of the scheme, and are said to contemplate the absorption of the new undertaking. Sir J. J. Jenkins is, however, of opinion that the powers actually obtained place his company in a formidable position in respect to the Great Western Railway.

NEW TINPLATE WORKS.—The expected development of the manufacture of tinplates in the United States does not seem to have the effect of diverting capital from new undertakings at home. It has been decided to erect another works, with three mills, in connection with the Briton Ferry Steel Company, near to the Villiers Tinplate Works at that place.—Bessemer steel coke tinplates per box I.C. are quoted at 18s. to 18s. 3d., 6d. more being asked for Siemens quality. Plates are accumulating at the Swansea Docks, all of which are sold, and are only waiting for shipment.

CARDIFF, 25th March, 1891.

IRON AND STEEL.—The hematite iron trade is still unsatisfactory. A reduction in the price of fuel and iron ore has been again discounted by another fall in the price of iron. In the Bessemer departments there is no better prospect, and tinplate makers refuse to purchase beyond June next, pending the result of the McKinley tariff. In the iron ore trade business is dull. The mine owners in Spain maintain their price very well, and good ore is in very fair demand. Rubio ore is quoted at 13s. 3d. to 13s. 6d. c.i.f. Cardiff or Newport, 14s. 3d. to 14s. 6d. c.i.f. Tees, 14s. 6d. Glasgow, for 50 per cent. iron.

COAL AND COKE.—There is a slightly better tone in the steam coal market, and one or two large contracts have been received. The prospect for the next few weeks is by no means discouraging. Prices for steam coal are as follow:—No. 1 quality, 14s. 9d. to 15s. 3d.; No. 2, 13s. 9d. to 14s. 3d.; No. 3, 13s. to 13s. 6d.; No. 4, 12s. 6d. to 12s. 9d. Small steam coal, 5s. 6d. to 5s. 9d. In the house coal trade there is a steady business, and prices are quoted at 15s. to 15s. 6d. for best No. 3 Rhondda; No. 2, 12s. to 12s. 6d. Patent fuel is active at 13s. to 13s. 6d. per ton. For coke there is only a small demand, the depressed state of the iron trade having affected this department. Furnace coke realises 19s. to 19s. 6d. per ton; foundry, 22s. 6d. to 23s.; best foundry, 24s. 6d. to 27s.

BARROW-IN-FURNESS, 25th March, 1891.

HEMATITE.—There are further signs of depression in the hematite pig iron trade. Few orders for forward delivery are taken, and the business for prompt delivery is very quiet. Hematite warrants have gone down in price to 48s. per ton, and makers find it impossible to sell Bessemer mixed numbers at less than 50s. to 52s. per ton. They are engaged on old contracts, and when these are done, if prices are still unremunerative, it is evident that more furnaces will have to be shut down. There is in the meantime a gratifying reduction in stocks, the decrease this week being over 4,000 tons, but the aggregate of stocks still stands at over 190,000 tons, or about eight weeks' make at the present rate of output.—The Solway Hematite Iron and Steel Company, Maryport, have posted notices that on and after April 3rd the services of all workmen and contractors employed by them will no longer be required. Upon inquiry the manager stated that the company had not considered the question of reduction in wages, but that, finding it was out of the question to make hematite pig iron at a profit owing to the abnormal prices of fuel, they had determined to temporarily close the works.

STEEL.—A very quiet tone continues to characterise the steel trade. Orders for rails are only few, although it is known that some large foreign contracts are in the market, which it is evident will be taken at lower prices. Heavy rails are at £4 12s. 6d., light rails at £6, and colliery sections at £7. In steel shipbuilding material there is only a small trade. The general steel trade in the Siemens-Martin department is quiet, and very little is being done in tinplate bars.

SHIPBUILDING.—The "Empress of Japan," the second of the Canadian Pacific steamers built at Barrow, has left the port for her trial trip, and the third of the fleet, the "Empress of China," was launched on the 18th inst. Some new orders of importance are expected, and a continuance of activity in the shipbuilding and engineering departments may be looked for.

A NEW INDUSTRY.—At length the arrangements for the transfer of the Vulcan Steel and Forge Works at Barrow to the Tubular Frame Waggon Company, Limited, have been completed, and the new owners took possession this week. They have orders in hand for the construction of bogie waggons about 32ft. in length for foreign railways which will keep them fully employed for fully two years to come.

MIDDLESBROUGH, 25th March, 1891.

THE IRON MARKET.—The iron market has been very dull during the past week, and business is almost at a standstill. Messrs. Walker, Maynard, & Co. are blowing out one of their four furnaces at the Redcar Iron Works, and Messrs. Bell Brothers have decided to blow out two of their Walker furnaces. The furnace at Redcar has been producing Cleveland iron, and the Walker furnaces hematite. With this decrease in the production of iron, and therefore also in the consumption of materials, the price of the latter must be lowered. Merchants are quoting 40s. per ton for f.o.b. deliveries of No. 3 G.M.B., but this is only nominal, and no business is done, seeing that Middlesbrough warrants have dropped down to 38s. 8d. buyers, and sellers a penny more. No quotations for forward delivery can be obtained under the present depressing circumstances.

SHIPMENTS OF PIG IRON.—Shipments do not improve, for the quantity of pig iron sent from Middlesbrough up to the 21st inst. was 45,698 tons, as against 56,014 tons during the same period of February. Of the 45,698 tons, Scotland took 24,380 tons, England and Wales 5,671 tons, and foreign countries 15,557 tons. There is a marked decrease in foreign shipments, which are 12,000 tons less than during the same period of March last year. Connal's stock is 123,983 tons, a decrease since the beginning of the month of 195 tons. East Coast hematite pig is quoted at 54s. per ton for mixed numbers f.o.b.

MANUFACTURED IRON AND STEEL.—There has been no change in the prices of manufactured iron and steel, but the demand is very poor. Steel ship plates are £6 2s. 6d., iron ship plates £5 12s. 6d., and heavy steel rails £4 12s. 6d.

COKE.—Coke is being reduced in price quickly, and several sales of fairly good sorts have been made here at 14s. per ton, though 14s. 6d. is still asked for the best kinds.

PROPOSED REDUCTION OF WAGES.—The masters and the men had a meeting yesterday to confer on the reduction of wages demanded by the masters. The men's delegates offered to take 5 per cent. reduction, but the masters demanded 12½ per cent. The meeting was then adjourned till April 7th for the delegates to consult their constituents.

NEWCASTLE, 25th March, 1891

THE IRON TRADE.—The statistics of production and selling prices, which are obtained periodically by direction of the Board of Conciliation and Arbitration, for the North of England manufactured iron trade, have just been published. The production in the two months, ending on the 28th ult., fell considerably short of the production in the preceding two months, the figures for each period being 48,961 tons and 38,928 tons respectively. As compared with the corresponding periods in 1889 and 1890, the output for the last two months shows a still greater falling off, and the figures exhibit a marked slackness in the trade. Fortunately prices have not declined in proportion to the output, the average selling price for the two months being £5 17s. 11d., or 1s. 10d. per ton less than the average price for the previous two months. According to the sliding scale arrangement, this small reduction of price will not affect the rate of wages, which, though estimated to be 17½ per cent. above the minimum of three years ago, will remain the same up to the end of May as they have been in the past six months. In galvanising works there is rather less activity, and in both forges and foundries there is a lessened pressure of work. Rivet works are also short of orders, and one establishment which has been closed for some time is, with its plant and machinery, advertised for sale.

THE COAL TRADE.—The state of the local coal trade continues satisfactory, the demand for household and manufacturing qualities being specially brisk. There is also a fairly good business in other descriptions, and the whole of the pits in the county are now working. The construction of the new coal shipping staiths at Tyne Dock is being pushed forward, and it is thought they will be ready for use at an earlier date than was at first anticipated.

ASSOCIATION OF STUDENTS INST.C.E.—The first ordinary meeting of the Newcastle-upon-Tyne Association of Students of the Institution of Civil Engineers was held in the Durham College of Science, Newcastle, on the 18th inst., Mr. Charles A. Harrison, M.Inst.C.E., presiding. The secretary reported that an excursion had been made on the 14th inst. to Wylam Railway Bridge. Mr. Hubert Laws, M.Inst.C.E., had conducted the party, and at the point where the railway crosses the Newcastle and Gateshead Water Company's 30in. main pipe, read a paper, in which he described how, during the construction of the railway, when it was found necessary to lower this pipe, the work was successfully accomplished without interrupting the supply. The bridge itself and the method of its erection were also clearly described. The hon. secretary read Mr. W. G. Laws' paper on "The Railway Bridge over the Tyne at Wylam" (*Min. Proc. Inst.C.E.*, Vol. LVI.). Mr. Laws then gave an instructive discourse on the various forms of iron bridges, and replied to a number of questions raised regarding the paper. The original drawings of Wylam Bridge were placed at the disposal of the Association for the evening by Mr. C. A. Harrison. Mr. Laws also showed photographs of the bridge in various stages of construction.

GLASS WORKS.—Flint glass works are still very slack, and manufacturers of lamp chimneys and similar specialties have few orders. The Tyne Plate Glass Works, South Shields, are still only in partial operation. In the glass bottle trade business is good, and the works at Blaydon are briskly employed.

DUNDEE, 25th March, 1891.

JUTE AND FLAX TRADES.—Business in both branches of the Dundee trade is quiet. Raw jute is, according to cablegram from Calcutta, lower in price. There is a fair business here at recent prices. Some speculative sales of the 1891 crop are already reported—an unusually early date at which to commence the new season's business. The price of the August-September shipment is £12 10s. for first marks. Jute spinners and manufacturers maintain their position, and prices are steady. There has been a rather better inquiry for flax and tows at firm rates. Yarns are quoted at better prices, and the tendency of the market is stiff. Foreign orders for linens are coming in pretty well, and there is a fair average business passing on home account.

TRAMWAYS.—The Dundee tramways, which were laid by the Corporation thirteen years ago, have been worked by a company from the first, but scarcely a year has passed which has not brought loss to the lessees. By their contract the company pays 5½ per cent. on the cost of one of the lines, and 6½ on the cost of another. It is also held bound to maintain the line—an arduous undertaking considering the heavy nature of the general traffic. The company has submitted a proposal for the revision of the contract, so that the rent may be made 7 per cent. on the cost, on condition that the Police Commission maintains the line.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 27TH MARCH, 1891.

THE SHIPS OF THE FUTURE.

THERE are many and multiplying evidences that the arts of the marine engineer and of the naval architect are neither lost nor inactive. There has probably never been a period when so much enterprise, such bold and original conceptions, and such far-reaching designs were being put forward as there are at the present day. It might have been supposed that, after the enormous development that has taken place in the shipbuilder's art during the last twenty years, there was little more to be said or done, and that both shipbuilders and shipowners had only to rest and be thankful. Instead of this, however, we find that the heights already "reached and kept" by the marine engineer are only regarded as gentle eminences from which to view the promised land that lies far away, and that there is no idea of finality in the possibilities of the future. Only a few months ago Sir Nathaniel Barnaby expressed his opinion that "we shall get the mastery over the seas, and shall live more happily in a marine residence capable of steaming 15 knots an hour than we can ever live in seaside towns." As a contribution towards this end, he proposed to construct a vessel 1,000ft. long and 300ft. broad, with engines of 60,000 horse-power, and capable of steaming at 15 knots. Such a ship would be, in point of fact, a steel island, incapable of entering any dock, and having still-water harbours or docks within the vessel herself, entered by gates in the sides, where she would carry loaded barges and tugs. Sir Nathaniel has satisfied himself that such a ship could be made absolutely secure against fatal injury arising from perforation, but she would require to be fortified and garrisoned like a town. This is undoubtedly a bold idea, and one that opens up a wide vista of possibilities in the future. Lord Brassey, in his admirable paper read last week at the meeting of the Institution of Naval Architects, defined the requisites that were, in his opinion, called for in different types of warships, and indicated the desirability of keeping the dimensions of warships within 10,500 tons, rather than increasing them to 14,000 tons, which has been considered in some quarters a practicable limit. One advantage of such an arrangement would be that the same tonnage would, by a reduction of the maximum, give eight ships instead of six. This view of the future policy of warship construction has been approved by Sir N. Barnaby, who says that "a large naval Power, having very widely spread interests, and subject to modern modes of attack, would suffer more in a war from fewness of ships than from comparative smallness of size of ships and of crews." In the next sentence the same authority appears to draw a sharp distinction between warships and merchant vessels, in reference to the question of dimensions, for he adds that "the advantages arising from size in a passenger ship seem to me to be so great that I do not see where we shall stop."

It appears, therefore, as if the shipbuilding programme of the future were to be directed to increasing still further the size of passenger or merchant ships, and decreasing the size of war vessels. This policy has, indeed, received the sanction of the most eminent naval authorities of the day, and it is sanctioned by the accumulated experience of the greatest naval Power in Europe. The main object of a navy like ours is that of protecting our commerce, which, as Lord Brassey told his audience last week, is always afloat to the value of over 150 millions sterling. That commerce is likely to be much more effectually protected if the merchantmen which compose the mainstay of British commerce are to be increased in size, so as to limit their number relatively to the work to be done, and if the warships which are to protect them are so far increased in number as to be more widely scattered over the wide dominions belonging to the English Crown. According to a table submitted by Lord Brassey, the total strength of the British navy at the present time is 170 vessels of all kinds—of which 32 are first-class and 13 are second-class battle-ships—having a total tonnage of 921,000. The average tonnage of the first-class battle-ships is rather over 11,000, so that it exceeds the limit fixed by Lord Brassey as most convenient and desirable. It is probable that this limit will be steadily reduced in the Admiralty programme of the future, and that our naval administrators will aim rather at a handy, easily manageable size of vessel, possessed of adequate speed and sufficient coal endurance, rather than a naval colossus, with armaments that may, indeed, be powerful on paper, but which experience has proved to be wanting in power in cases of emergency. The future marine architect must study compressibility, and must secure the maximum of speed and of fighting power with the minimum of size.

But the remarkable scheme for a new type of merchantman propounded by Sir Nathaniel Barnaby appears to point to the possibility of a ship that will be competent to undertake either aggressive or defensive warfare. He speaks of a vessel "fortified and garrisoned like a town." Such a ship would probably be able to undertake its own defence, and to give a good account of itself in any emergency that it might be called upon to face. In such an event, how far would our naval strength be required for defensive purposes? There would seem to be a possibility of having each individual merchantman constructed like and as a fortress, with both carrying and defensive capacities far in excess of anything hitherto dreamt of, but limited in speed by reason of its unwieldy proportions. In merchant ships, as in factories and workshops, economy of working is a concomitant of size, and it is hardly to be doubted that a "floating island," like the vessel contemplated by Sir N. Barnaby, if practicable at all, would be more economically worked than a number of smaller vessels of nominally the same carrying power. There is only one serious drawback to this magnificent scheme. It is doubtful whether the "floating island" could even approach some of the principal docks and harbours, although Sir N. Barnaby appears to think that a draught of 26ft. of water would be sufficient; but even if this were so, there are not many ports that could furnish the cargoes necessary to fill up such a structure, and hence it could only be used, if used at all, between the largest ports, such, for example, as those of Liverpool and New York. The idea of a vessel of 1,000ft. in length engaging in the business of an "ocean tramp" is hardly to be seriously entertained. If it should be found that a structure like that described should be the ship of the future, and if it should

Digitized by Google

appear that by some such vast leviathan the mastery over the seas is to be obtained, the future would be likely to witness developments of shipbuilding and marine engineering far more notable than anything hitherto attempted or achieved.

THE INSULATION OF OVERHEAD WIRES.

The London Chamber of Commerce has circulated a *résumé* of the Overhead Wires Correspondence. The difficulty is this: The Board of Trade has issued rules, according to which a 2,000 volt circuit, however small the wire, must have an insulation of at least a tenth of an inch, and the wires must be suspended from supporting wires by means of non-metallic ligaments. Electrical engineers object to these regulations when applied to very small wires, such, for instance, as $\frac{7}{16}$in. cable.

As the questions of insulation and suspension are independent, they may be discussed separately. Electrical engineers argue that much less than one-tenth of an inch is enough for a small cable, and that using a thicker coating does not materially improve the insulation, while it makes the wire more liable to injury due to kinks, and makes it also dangerous in gales or snowstorms. Major Cardew, on behalf of the Board of Trade, replies that gales and snowstorms will do no harm if the cables are properly suspended according to the regulations, and that thickening the coating of dielectric must improve the insulation, other things being equal. But in such a case a great deal depends on what is meant by insulation. The question is, What is the duty of the insulation in an overhead wire? If it is covered by a metallic sheath the need for insulation is obvious; but if merely suspended in the air the insulation is a protection needed only in the case of accidental contacts. Though the chance of accidental contact in the case of any one wire is small, if many overhead wires are used the probability of somebody touching one is much greater, and the consequences would be so serious that bare wires are out of the question. Measurements of the insulation in megohm miles give little useful information, as there is no reason to suppose that a cable which gives good results in this way is good for overhead work. With a given quality of dielectric the insulation resistance in megohm miles depends only on the ratio of the diameters of the bare and covered wires. If a 2in. cable gave a high enough insulation test with a tenth of an inch of rubber on it, a No. 25, which is one-fifth of an inch in diameter, would give the same insulation in megohm miles with a covering only one mil in thickness. It would then be quite useless for high pressures, as it would break down at once, whereas the 2in. cable might stand perfectly. In an article which we published recently, it was pointed out that what is probably needed is capability to withstand disruptive breaking down of the dielectric, and not necessarily high insulation, and that this capability most likely depends, not only on the nature of the dielectric, but on the electric stress to which each layer of it is subjected. Let us take the case of the 2in. and No. 25 leads again. If the resistance in megohm miles is kept the same, the insulation of the small wire has just 100 times as many volts per mil on the insulation, and would, of course, break down much more easily. Suppose the insulation test of the 2in. cable to be 1,000 megohm miles, and suppose it is subjected to 1,000 volts. As the thickness of the insulation is small in comparison with the radius of the cable, we may take it that there is a fall of potential of 10 volts per mil in the dielectric. In the small wire, with the mil insulation, there is, of course, 1,000 volts per mil. Suppose the small wire is now insulated with one-tenth of an inch dielectric. The insulation resistance in megohm miles varies as the logarithm of the ratio of the bare and covered diameters. It is thus 25,000 megohm miles—that is to say, not 100, but only 25 times as much. Though the insulation resistance is enormously increased, the stress on the inner layer of dielectric is 42 volts per mil, or more than four times as much as in the case of the 2in. cable. This stress cannot be much reduced without increasing the covering of insulation to an absurd extent. We thus find that for a given electromotive force there is a size of wire below which the stress on the dielectric is too great, with any insulation within reason. If a needle point is inserted in a piece of rubber and put under electric pressure, probably the dielectric breaks down round the point, and becomes virtually part of the conductor, which increases till there is practically a round knob, so that there is no longer excessive stress on the inner layers.

However this may be, it is most probable that it is much more difficult to insulate against disruption in the small wires than in the large, though it is much easier to get megohm mile insulation. In the case that actually came up, of $\frac{7}{16}$in. cable, one-tenth of an inch insulation means a fall of 29 volts per mil at the surface of the copper under 2,000 volts; if the coating is only one-twentieth of an inch there are 50 volts per mil. The insulation in megohm miles, however, in the latter case would be equal to that of a 2in. cable covered with five-eighths of an inch of rubber.

The question of cracks and minute leaks is, of course, of the greatest importance. It is quite out of the question to attempt to make the insulation so thick that a crack in it will not matter. The striking distance of 2,000 volts may be under a tenth of an inch, the creeping distance is quite another thing. In clean places an inch or so is little enough to allow. The way 2,000 volts will creep over apparently clean surfaces is astonishing. As thickness of insulation will not avoid faults from cracks once the cracks are formed, it is important to know whether a thin or thick covering is least likely to crack. We should think the cable makers would be able to answer this question. The Board of Trade seems to prefer to consult the Council of the Institution of Electrical Engineers. But this is like leaning upon a broken reed, and it would be much more to the purpose to take the opinions of cable makers and contractors who have had to do with high-pressure distribution.

As to suspending the wires, the first thing that strikes one is that if the overhead wires are sheathed with a metal covering, which is itself earthed, there is no object in insulating it by means of non-metallic suspenders. In any case, non-metallic suspenders are unnecessary. The engineer who puts his trust in several imperfect insulators in series always finds himself in trouble. If the covering of the cable is good, the whole duty of insulation should be entrusted to it. Leather or similar ligaments are useless. They get dirty and wet, and 2,000 volts can creep easily along them. The only safe rule in high pressure work is to consider all such substances as leather, wood, fibre, paper, and all exposed surfaces that may get dirty, as perfect conductors, and not to depend on them for insulation in the least. Then, if a cable with an earthed sheathing is safe, why not earth the suspending wire and use mechanically good suspenders. The suspending is in contact with the insulation at points only, while the sheath is in contact all along, and is therefore much more likely to come in contact with the cable. Why contractors should argue that suspending is less needed in small than in large cables we cannot understand. Of course the cost per ampere is greater in the case of the small cables; but the factor of safety is much greater with the large ones, as the cross section of copper is much greater in proportion to that of the whole cable.

However these matters may really be, it is most important that in any points on which the adviser of the Board of Trade wants additional information he should refer to people conversant with the subject. The Board of Trade are in a position which, without the greatest care, may lead to great difficulties in electric lighting. If a rule is made lax, and an accident happens, it can be brought home to the Board of Trade at once. If the rule is made too stringent, and industry is hampered, nothing can be directly brought against the Board of Trade. It is therefore strongly to its interest to make the rules as stringent as possible, and not to consider the difficulties thereby thrown in the way of industry, but it is earnestly to be hoped the Board of Trade will take a broad view of such questions, and not sacrifice the progress of electric lighting simply in the interests of its own reputation.

ENGINES IN THE NAVY.

The Parliamentary Return which was recently issued, showing, in regard to ships launched since January, 1883, the estimated and actual speed, and the estimated and actual horse-power, is a very complete and instructive paper, and will be studied by engineers with great care. In each case it gives the class of the ship, its name, the date of its launch, and when it was completed, the periods during which it was in commission, and by whom the engines and boilers were designed and constructed. It then gives details of the official steam trials, and why they were repeated when that occurred, and the nature of the casualty or the reasons why the contract was not strictly fulfilled. Returns are then given regarding the speed as estimated in the design of the ship, as reported on the measured mile, and as at present estimated under continuous steaming, and each of these in many cases both with forced and natural draught, and similar figures are given for the indicated horse-power under the same conditions. A column is set aside for the duration of steaming at contract horse-power before receipt, and in cases where subsequent defects of importance have been discovered in the machinery and boilers, these have been reported up to 1st of January, 1890, and the cost of making them good duly noted. Special returns are given of the renewals of tubes both in the boilers and condensers, when these have been due to defective material. The last column notes the occasions on which the measured mile speed and horse-power have since been developed. The return was ordered at the instance of Lord Randolph Churchill, but it is quite evident that his lordship has had the benefit of the advice of an engineer who knew the points on which it was desirable to obtain accurate information.

We will not attempt to reproduce all the returns, but would advise our readers to obtain them and study them for themselves. There are, however, a few points to which we wish to direct attention. And first, with regard to speed, we are struck with the comparatively small number of ships which have not been tried on the measured mile, or under measured mile conditions. We think that Members of Parliament, for whose special benefit this return was made, should inquire why this is so, and indeed why any ship should be taken over without having been tested in the manner stated in the contract. When we compare the speed estimated in designing the ship, and that at present estimated under continuous steaming for ninety-six hours with smooth water and clean bottom, we observe a very great deficiency, in some cases amounting to almost four knots. In the same way the indicated horse-power under the last conditions is very much under the estimated power when designing the ship, and also very much under what was reported on the measured mile. It seems very odd that observations on the indicated horse-power have been made when the ship was running the measured mile, and none on the speed, which is supposed to be the main object of the trial. This is another point which requires explanation. It is satisfactory to find that when the official trials required to be repeated the defects in the machinery appear to have been of a comparatively slight nature, and such as could easily be put right, if we except a few cases in which bad condenser tubes had been used, and of which we think we have heard before, and the cost of making good comparatively small. Such returns are of the greatest use not only to engineers, but also to the general public, and we hope we shall have more of them in the future than we have had in the past.

IRON AND STEEL WIRE ROPES.

Mr. A. H. Stokes, Her Majesty's Inspector of Mines, read last Friday before the Derby Society of Engineers an interesting paper on "Iron and Steel Wire Ropes, Chemically, Microscopically, and Mechanically Considered." The importance of the subject was shown by pointing out that in the United Kingdom alone upwards of 500,000 lives were daily trusted to the efficiency of these appliances. Wire ropes, the author explained, are divided into three great classes, according to the material from which they are made—viz., iron, steel, and plough steel. The average breaking load of iron wire ropes is 20 tons; of steel, 35 tons; and of plough steel, 50 tons per square inch of sectional area. The safe working load for iron wire ropes is 2 tons; for steel, $3\frac{1}{2}$ tons; and for wire ropes of plough steel, 5 tons per square inch. It will thus be seen that a limit may soon be reached—but soonest in the case of iron—when the weight of the rope alone is all the load that the wires of which it is made up can safely carry. The increasing depths of our coal mines compelled the introduction of materials of greater strength, although Mr. Stokes is of opinion that for reliability the old charcoal iron has not yet been excelled by its modern competitors in the various qualities of steel. An iron wire rope reaches its limit of safety at 3,000ft., one made of steel wire at 4,790ft., and one of plough steel at 7,185ft. The difficulty of raising minerals from increasing depths has been overcome by making the ropes of a taper form, so that as the rope is paid out and the suspended weight increases, so also does the sectional area of that part of the rope supporting the weight go on increasing. As, owing to inertia, the working load increases considerably with augmenting speed—so that a velocity of 30ft. per second actually doubles the load—it is easy to understand that ropes are severely tried just where they show over the drum from which they are suspended when the cage is at the bottom of the pit. To avoid the danger arising from this source 6ft. or 7ft. of the wire rope are cut off from the cage end every two or three months and newly fastened, so that the severe straining mentioned comes on different parts of the rope. By this means the life of a wire rope, with proper care in other respects, may be safely taken at two and a half years. Owing to internal corrosion, which it seems impossible to arrest by any known means, it is quite unsafe to work them longer for raising purposes, whatever their appearance may be after this period of use, or even of rest, if they have been exposed.

Digitized by Google

Mr. Stokes went fully into the question of testing wire ropes, and, putting aside as impracticable chemical and microscopical tests, however interesting from a scientific standpoint, he showed how by very simple mechanical methods the colliery manager may assure himself of the fitness of a rope for its intended work. The tensile resistance of the wires is readily ascertained by taking out a few feet of wire from one end of the rope. Suspending the wire from some convenient attachment it is made to hold up an empty tub at the lower end. Water is then carefully poured into the tub until when the tensile limit of the wire is reached it breaks. Afterwards the water in the tub can be measured and the breaking strain calculated. The resistance to torsion is, however, of no less importance, and a method that could be readily applied where testing machines were not at hand was described. For this purpose a piece of the wire to be tested, 8in. long, is screwed up tight at one end in an ordinary smith's vice, and the other is held fast between the plain faces of a pair of dies in stocks, which have only to be rotated, and the number of whole turns before the wire breaks carefully counted, to ascertain the torsional limit. Steel wire should stand twenty-eight twists. Great care has to be taken that the wire is properly fastened at each end in this test, and hence it is well to have the wire marked and watched whilst the test is proceeding.

During the discussion Mr. Fletcher remarked that he had found it of service to draw a line along the wire before subjecting it to the torsion test. As the wire is twisted this line forms a screw, the number of turns actually performed by the wire before it breaks being readily counted. Mr. Carulla observed that much excellent steel was manufactured in Sheffield for wire-rope purposes from Bessemer scrap. The scrap was re-melted in crucibles by the old cast steel process, and there could be no question that a more reliable material was thus obtained for wire-rope purposes than was the case if got direct from the Bessemer converter, or even the Siemens furnace. The scrap being cut up small, and care generally taken to have it as nearly alike as possible in temper, a very uniform product is the result.

Replying to a question, Mr. Stokes explained the method adopted to ascertain the presence of broken wires in any rope. For this purpose a piece of spun yarn is just looped around the rope, the spun yarn being held by two men, one at each end, as the wire rope is slowly lowered through the loop, which is in close contact with the rope. The projecting ends of any broken wires catch on the spun yarn, and in that way reveal the defect.

MANCHESTER JOINT BOARD OF CONCILIATION.

We are much pleased to note the growth of the application of a method of settling trade disputes which we have often advocated—namely, by means of Boards of Conciliation. The past year has been one of great unrest in the labour world, but it has not been without some symptoms of the advent of a better state of affairs, for thinking men of all classes see that the present state of unstable equilibrium is most hurtful to the best interests of the country. For some months past negotiations have been carried on between the Manchester Chamber of Commerce and the Manchester and Salford Trades Council for the establishment of a Board of Conciliation, which is intended to bring about a speedy settlement of trade disputes between employers and employed, and regulations have been adopted which have received the approval of the Chamber of Commerce and of the Trades Council, of which the following are the most important:—The extent of jurisdiction is unlimited as regards the nature of the trade or industry, as any trade may make application for the services of the Board in any existing or anticipated dispute. As soon as it comes to the knowledge of the secretary that any serious labour difficulty has arisen, it shall be his duty to summon a meeting of the Board to consider the propriety of offering its services with a view to a peaceful settlement of the difficulty, and, if so decided, shall arrange for a conference between the disputants. In the event of the disputants not being able themselves to arrive at a settlement, they shall be invited to lay their respective causes before the Board with the view of receiving its advice or mediation. The utmost efforts of the Board shall in the meantime be exerted to prevent, if possible, the occurrence or continuance of a strike or lock-out. The decision of the Board shall not be necessarily binding upon either of the parties to the dispute, except when a joint application has been made and an agreement come to on the part of both disputants that they will respectively abide by the decision of the Board. In other cases, when an award is agreed upon, the decision shall be made public on the authority of the chairman, with such comments as shall be approved by the Board, but in the event of the decision not being unanimous, the report of the minority, if they desire it, shall also be published. Upon the occasion of an equality of votes, so that no definite award can be given, then the chairman shall make an announcement to that effect, and at the request of either of the parties to the dispute shall publish such separate report or reports as they may wish to have made public. Arrangements are made for calling in the assistance of expert members, two for each party, who may express opinions, but who shall not be allowed to vote.

The Board is to be affiliated to the Manchester Chamber of Commerce, and it is to be composed of six members representing employers, to be elected by the directors of the Chamber, and of six members representing employés, to be elected by the Manchester and Salford Trades Council. Regulations are laid down for the management of business and the duration of service and retirement, which seem well designed to meet the requirements of the case. We wish the Board all success, and look forward to its operations with much interest.

THE CENTENARY OF THE AMERICAN PATENT SYSTEM.

The celebration of the beginning of the second century of the American patent system, by inventors and manufacturers of patented inventions is about to be held at Washington from the 8th to the 10th prox. A very influential and numerous executive has been formed, with Mr. J. E. Williams, of the United States National Museum, Washington, as secretary. In a circular issued to inventors and manufacturers of inventions in America the secretary states:—"The completion of the first century of the American patent system marks so important an epoch in the history of the nation that it is eminently proper that the beginning of the second shall not pass unnoticed. The centennial anniversaries of other important national events have been celebrated in a manner worthy of a people proud of their country and its growth. Surely the system that has aided the agriculturist in the field, the mechanic in the shop, and the toiler in the mine, and has stimulated invention and helped every branch of modern industry, has played no small part in a history so full of the triumphs of human achievement. Believing that the American inventor and manufacturer of inventions will regard it a privilege as well as a duty to co-operate in making due recognition of these facts, it is proposed to hold a celebration at the National Capital in April, 1891, which shall, in a fitting manner, commemorate the important event, and place on record the nation's appreciation of the labours of those whose ingenuity, patience, and tireless effort have exercised such a potent influence in accelerating the prosperous growth of the nation, and in aiding the progress of our civilisation."

It is also proposed to form a "National Association of Inventors." The first public meeting, which will be presided over by the President of the United States, will be held on April 8th. Another meeting of a similar character will also take place on that date, which will be presided over by the Hon. John W. Noble, Secretary of the Interior. A special reception of inventors and manufacturers will be held at the Patent Office on the morning of the 8th, by the Secretary of the Interior and the Hon. Charles Eliot Mitchell, Commissioner of Patents. Two meetings will also be held on April 9th, and will be presided over by the Hon. Frederick Fraley, LL.D., and Professor S. P. Langley, LL.D. On the 10th, being the anniversary day of the signature of the first American patent law by George Washington, there will be an excursion to Mount Vernon, where an address will be delivered by J. M. Toner, M.D., upon "Washington as an Inventor and Promoter of Improvements." A long list of addresses on suitable subjects has been arranged for these meetings.

Letters to the Editor.

THE INSTITUTE OF CHEMISTRY.

To the Editor of "Industries."

Sir,—I have read with much interest your two articles on the Institute of Chemistry, and also the letters from your correspondents on the same subject. I note that a contemporary, on the publication of your articles, took exception to the ventilation of the subject in your columns, on the ground that there were special chemical journals which were available for the subject, but it is obvious from the interest displayed in the subject that it was waiting to be discussed, and I for one am glad that you have been able to devote so much space to the question under discussion. Although I agree with the writer of the articles in his wish for reform in the management of the Institute, I think that many of the Fellows will be of opinion that the general tone of his remarks might have been couched in a somewhat less radical form. It is always difficult to bring about changes, but the difficulty is often enhanced when drastic measures are resorted to, and the reformation and development of the Institute of Chemistry which the main body of the Fellows desire is, I believe, making progress, although perhaps not so rapidly as the writer of the articles wishes. Your correspondent, "A Technological Associate," points out that the Institute of Chemistry does not exist for one special class of chemists, and it must be the general opinion that it would be a great mistake to narrow its functions in any way. What we want is undoubtedly an institution which will confer upon its members a distinct qualification which will be publicly recognised as a stamp of a man's chemical knowledge being of a standard sufficient for his advice to the public to be of value. The great obstacle in the way is the magical influence of the letters "F.C.S." upon the general public, and the Institute will only succeed in raising itself to its proper level by demonstrating to the public that the Chemical Society has ceased to be, if it ever was, a diploma-giving body, and that when it obtained its present charter the Chemical Society then relinquished its position as a body of professional men for that of a scientific club.

Yours, &c.,

London, 21st March, 1891. Alchemist.

To the Editor of "Industries."

Sir,—Permit me to offer a few remarks on the articles on the Institute of Chemistry which have recently appeared in your valuable journal. The cosmopolitan nature of your readers assures me of a more generous and impartial hearing than I should receive in a paper devoted solely to the interests of chemists.

To credit the general public with a mere pittance of common sense is impolitic on the part of your contributor, who might also have omitted the overt sneer at the biographer, and have shown some appreciation of the work the professor and his kin have done for the advance of analytical chemistry. A modicum of good taste would have kept hidden such narrow-mindedness. Your contributor wishes to "convert the practice of chemistry into a close profession," or, failing such happy consummation, to sail as near the wind as possible in that direction. But the engineer and industrial man, if not the maligned general public, will protest against the establishment of such a monopoly. The monopolists, indeed, would prosper, and by lauding the merits of their Institute to the skies, would perhaps—nay, assuredly, if the writer of the articles judges its discrimination aright—deceive the community at large. But a system of high fees, engendered and maintained artificially, will perforce compel the public to appeal as seldom as need be to the analytical and consulting chemist, and the profession thus handed over for nurture to a self-seeking oligarchy will in the end suffer. The simile drawn from the legal profession is infelicitous, and those of your readers who have made acquaintance with lawyers' bills will doubt the expediency of permitting analysts to become a similarly protected class.

Such protection will be attained by increasing the difficulties of qualification, and the essential weapon wherewith to cope with these difficulties will be sufficient means for a protracted course of study. Thus the way will be barred to many a man who would otherwise become an ornament to the profession, but who cannot face such prolonged and expensive apprenticeship. This is surely contrary to the spirit of the age.

The predominating influence on the Council of the scholastic and collegiate branch of the profession is deprecated, but with what reason? The practising analyst and consulting chemist is generally a man of less marked ability than his compeer on the professorial branch, and he displays good sense in transferring the burden of government to the shoulders of the latter. In the welfare of the Institute of Chemistry the self-interest of the teacher is at stake, since unless the profession of analytical and consulting chemists flourish, his *raison d'être* diminishes, and he seeks a livelihood in vain, for the training of the rising members of that profession is his main support.

Yours, &c.,

Oxford, 19th March, 1891. Curculiunculus.

To the Editor of "Industries."

Sir,—To those who can read between the lines of your recent articles on "The Institute of Chemistry," the *raison d'être* is not difficult to discover, and they will summarise it as an attempt to convert the Institute into a trades union for the purpose of raising the standard of fees, or, at all events, of preventing the present standard from being lowered by unlimited competition.

The more thoughtful among the members of the Institute cannot but regret that such widespread publicity has been given to this article by its appearance in the columns of your paper; its circulation among the members was all that was necessary, for it is with them, and them only, that it is concerned.

In referring to the charter, of which "a careful perusal may be recommended," the writer has curiously omitted all mention of the clause on page 7, which reads as follows:—"That the said Institute was not established for the purposes of gain, nor do the members thereof desire to seek any pecuniary profits from their membership, but the society aims at the elevation of the profession of consulting and analytical chemistry, and the promotion of the efficiency and usefulness of persons practising the same. . . ." &c.

From this it is apparent to the meanest intellect that the Institute exists for the benefit of the public, and *not* for the benefit of the profession. That the Institute *will* ultimately benefit the profession is, of course, admitted, but to widely publish that such benefit is the object of its existence is a line of action which carries its folly in its face.

The one aim which all members of the Institute have in common is the attainment of Parliamentary powers for the purpose of preventing the practice of analytical and consulting chemistry by those who are not members of the Institute. It cannot be too strongly insisted upon that no Parliament will grant such powers, and that it is undesirable that any Parliament should grant such powers, to any corporation which has for its object the benefit of the profession rather than the benefit of the public.

Yours, &c.,

London, 20th March, 1891. Microscopist.

Legal Proceedings.

TUCKER *v.* KAYE.

This action, which is of interest to patentees, was tried by Mr. Justice Romer. It was brought by Mr. A. P. Tucker, the patentee under a grant, No. 5080 of 1886, in respect of an improved spring lock, against Mr. Kaye, a well-known lock manufacturer, to restrain an alleged infringement of the plaintiff's patent rights, and to recover damages in respect thereof.

The plaintiff's lock, as described in his specification, was designed with a view to avoid the use of bolts which project, when the door is open, from the surface of the lock plate. The ordinary spring lock has such a projecting bolt provided with a sloping surface, which comes into contact, when the door is in the act of closing, with the surface of the striking plate, and is so driven back against the spring, which, by its reaction, thrusts the bolt forward and into engagement with its catch as soon as the acting surface of the striking plate has been passed. The particular disadvantage of such locks, which the inventor had in view and avoided in his patented lock, is that the projecting bolt is apt when the door is swinging to catch in the clothes of persons passing or standing by and to tear or do them other injury. He therefore arranged his bolt so as to lie entirely within the lock except when actually in use for the purpose of fastening the door, and caused it to be held back against the pressure of its spring by a detent, which detent is automatically released when the door is closed by the action of a secondary bolt. The releasing bolt, if it projected from the face of the lock, would be just as dangerous as a projecting main bolt, and accordingly the inventor places it in a recess cut in the face of the lock, so that it does not project beyond the general surface, and on his striking plate he arranges a projection which, entering this recess when the door closes, acts then upon the releasing bolt and operates it to disengage the detent which holds back the main bolt. Such is in outline his description of his lock, which is claimed in the following terms:—"In combination with a main bolt urged forward by a spring a detent holding the bolt back when the door is open, but released by a projection on the striking plate in the act of closing the door substantially as and for the purpose herein set forth."

The defendant's lock which was complained of resembled the plaintiff's as above described in all material respects save one, namely, that the releasing bolt does project from the face of the lock. For the plaintiff it was contended that this was a merely colourable difference. For the defendant, on the other hand, it was contended that the difference was of vital importance, and that the plaintiff could not set up a claim to locks in which there were projecting bolts. Other objections urged against the patent were, that the lock described was not new in principle at the date of the grant, having been anticipated by earlier locks which had been used and described in printed books. For the printed anticipations the defendants relied upon Lord Grimthorpe's work upon Locks and the Eighth Edition of the *Encyclopædia Britannica*. In both these works spring locks are described, of which the bolts are held by detents when out of action and released by the automatic withdrawal of the detents effected in the act of closing the door. Various locks of such a type were produced and proved in Court. For the purpose of evading these anticipations, it was contended by the plaintiff that an important difference between the lock described by the plaintiff and those put forward by way of anticipation was that the anticipating locks had, all of them, projections standing out upon the side instead of the face of the lock, and actuated by being pressed against a flange upon the striking plate, or, as the case might be, the rebate of the door post. It was pointed out that a lock constructed in this way could not be used in all the situations for which a lock having facial action would be suitable. Thus, a right-handed lock of the earlier construction could not be used in place of a left-handed, nor could such a lock be applied at all to swing or sliding doors. To all these situations the plaintiff's lock was adapted quite indifferently.

In the result the judge found for the defendant on all the issues named. He held that there had been no such invention as to entitle the plaintiff to the grant of any patent at all, inasmuch as the principle of employing a secondary bolt to release the main bolt had been previously known, and no invention was required to remove the acting parts from the side to the face of the lock. The prior user of locks, having all the essentials of the plaintiff's lock, with the difference, which he had thus decided to be unimportant, of releasing mechanism projecting on the side instead of the face of the lock, had been sufficiently proved in evidence. There was, consequently, no novelty in the plaintiff's lock at the date of his patent. He held also that, as to the issue of infringement, the plaintiff had not succeeded in making out his case, for the use by the defendant of a bolt projecting from the face of the lock was sufficient to take his lock out of the plaintiff's claim when properly construed.

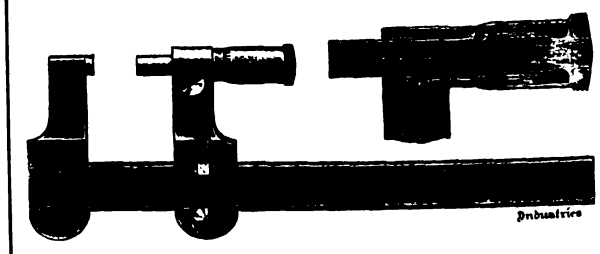
This case is interesting under two points of view—that is to say, for the light which it throws on the attitude which the new judge may be expected to take up with reference to patents, and also for its effect upon a commercially important patent. First, as to the disposition of the judge, the present decision appears to indicate that he may be expected to prove a somewhat exacting critic of patents. The tendency of the judges generally, and especially perhaps of late, has been to refrain from pronouncing a patent bad for want of invention, and rather to be ingenious in finding subject matter in very small improvements than severe upon this head. The present decision is, however markedly severe. It is, no doubt, perfectly true that any mechanician could have substituted the facial action for the lateral if he had been told to do so; but it does not by any means follow that any mechanician would necessarily have perceived that there was practical utility in so doing. The property of being universally adaptable without modification to any situation in which a lock can be required is certainly a valuable feature in Tucker's lock, but it is a merit not indicated in his specification, and so far is it from being an obvious advantage, that it is open to serious doubt whether the patentee had himself perceived it when he made his application for a patent. Such an oversight, if oversight it was, would not harm his patent, but it goes far to show that invention was implied in the result which the patentee obtained, and in view of this admitted merit of the lock which he was the first to describe the judgment against him on the ground of no invention is a little surprising. It is even the more surprising because the alternative ground of non-infringement, on which also the judgment against him was based, appears to be unassailably strong, and the question whether there was good subject matter or not did not actually need to be discussed for the mere purpose of deciding the action.

Upon the other point mentioned above, it is not necessary that we should comment, unless to remark that in this instance a valuable patent appears to have been destroyed through the faulty drafting of a claim. If, at the time when the complete specification was drawn, the patentee had apprehended the view of his invention which was put forward with great force at the trial, and had claimed a lock made so as to be universally adapted to any kind of door, he would no doubt have possessed a narrower patent; but, for all that has yet appeared, a good one.

THE PRINTING, STATIONERY, AND KINDRED TRADES EXHIBITION.

The above-named Exhibition was opened on the 16th inst. at the Agricultural Hall, Islington, and will close on the 30th inst. Although not very extensive, it contains many interesting exhibits connected with the engineering and printing trades.

The most imposing exhibit is that of Messrs. Joseph Richmond & Co., Limited, of 30, Kirby Street, Hatton Garden, London, E.C., who show about thirty machines for all purposes connected with the printing and stationery trades. A useful tool shown by them is a planing machine for getting up the surfaces of lithographers' stones, instead of the old method of grinding. We had an opportunity of seeing this machine at work, and of inspecting the very perfect surface of the stone afterwards. The saving in cost of grinding by the use of this machine is, we understand, considerable. A self-clamp guillotine exhibited by this firm is of neat design and finish. It works noiselessly, and gives a clean cut. The novelties in its construction consist in combining the tangent wheel motion with the diagonal slide motion of the crank, and the rigid connection of the knife-holder and the lower beam by means of rods, the whole being guided in slides. All these parts receive a direct pull from the crank in the direction of the cut, thereby ensuring steadiness in motion and freedom from jerking. The same firm also exhibit Pellatt's gumming machine. This machine can automatically fan out, gum, dry, and deliver envelope blanks at the rate of 20,000 per hour at an inclusive cost of less than a farthing per thousand. The power required for driving it is very little. It is exceedingly simple and requires no skilled attendant. Some of the machines made by this firm we hope to illustrate in a later issue. Messrs. James Salmon & Son, of Blackfriars Bridge, Manchester, exhibit a Wharfedale machine with flyers, and cutting and rolling machines. The Watford Engineering Works have a good show of a varied nature, including dynamos, boilers, gas retorts, and pulp strainers. Messrs. Joseph Foster & Sons, of Soho Foundry, and Bow Lane, Preston, show a double royal stop-cylinder printing machine, with flyers. On this machine is fitted Oldfield's multi-colour printing appliance, by which a number of colours may be printed from one forme at one operation. The Trent Gas Engine Company, New Basford, Nottingham, exhibit three sizes of "Trent" engines—viz., of 12, 6, and 1½ h.p. The Winder Type Composing Machine Company, Limited, of Bowker's Row, Bolton, exhibit their system of composing, which is well worth attention. It is extremely simple, and consists merely of eighteen castings from one pattern, bound together, into which are inserted tin tubes full of type as they come from the distributor. The "stick" is held in the machine, thus leaving the compositor two hands instead of one to pick up the type, which has to be conveyed only a few inches to the stick. The same firm also exhibit a new form of distributing machine. Messrs. H. Wallwork & Co., of Union Bridge Iron Works, Manchester, have on view Cartwright & Wallwork's litho roller covering machine, for putting on, taking off, and tightening skins.



Messrs. Weyman & Co., Limited, of Church Acre Iron Works, Guildford, show a 2 h.p. "Trusty" gas engine, on the four-cycle principle and with tube ignition; also a 2 h.p. petroleum engine, which consumes about ¾ pint of oil per h.p. per hour. Messrs. Furnival & Co., of 32, St. Bride Street, London, E.C., have an attractive stand of printers' machinery; they also exhibit a 7 h.p. "Express" gas engine at work. This engine is of neat design and is economical in working. Messrs. Dick, Kerr, & Co., Limited, of London, Bristol, and Glasgow, exhibit various sizes of "Griffin" gas engines, double and single acting, and electric lighting plant.

(*To be continued.*)

A BEAM MICROMETER CALLIPER.

The accompanying illustration, for which we are indebted to our esteemed contemporary, the *American Machinist*, shows a micrometer calliper, which is manufactured by the Standard Tool Company, Athol, Mass., U.S.A.

As will be seen, the instrument consists of a beam, upon which there are two heads or jaws, one of which is fixed, while the other is movable, and can be clamped at any point, according to the size of the work to be gauged. The edges of the beam are bevelled, and the sliding head is fitted to it closely without a gib, and is open on the front side, as shown, being tightened in position by the screw seen at the bottom, one side of the head of this screw being flattened at an angle to fit the bevelled edge of the beam, so that it acts as a gib. At intervals of ½in. along the beam are placed small pins. In the side of the moving head is a small key, which is let into a slot somewhat longer than the key, so that when the latter is pushed up to the top of the slot it will clear the pins in the beam, but when pushed down it comes into contact with them, and the two together then serve as a stop to fix the head on the beam. The key can be drawn

down to its place in the slot by a screw on the other side This key does not touch the beam, but just clears it, so that, after the key is drawn down to its place by the screw, the head can be moved up against one of the pins, and clamped by the screw at the bottom. The micrometer screw is ½in. long, corresponding to the distance between the pins, and, as shown by the sectional view of this head, is entirely covered. It is fitted to the nut A, and is provided with an adjustment for wear.

A new method of adjusting the screw, so that it will read zero when the contact points are brought together, is used, by which the screw in the fixed head is replaced by a pin, which is driven into place, and need not be moved afterwards. The adjustment is made by means of the screw C, which is tapped into the end of the micrometer screw as shown, and the end of the micrometer screw is bored out tapering, and split, so that when the screw C is tightened it expands the end of the micrometer screw and tightens it in the shell. Thus, when the micrometer is to be adjusted, the points are brought together, and the shell is then turned on the screw until it reads correctly when the screw C is tightened up. These callipers are made in two sizes for measuring up to 4in. and 6in.

A NEW TWIST DRILL.

The accompanying illustrations, for which we are indebted to the *American Machinist*, represent a twist drill and drill chuck of novel construction. The body of the drill is of the ordinary pattern, and is made to a standard size, the novelty in construction being in the shank of the drill and in the chuck. The groove, instead of terminating at the beginning of the shank of the drill, as is usual, is continued through it in the form shown in Fig. 1, and it is then held in a chuck, such as is shown by the engraving, which has two jaws adapted to fit the grooves in the shank of the drill, and to be clamped tightly in them by the threaded and milled sleeve shown. The jaws are not loose, and their distance from each other does not vary with the different sized drills placed in the chuck, since the shanks of the drills for a given series are of the same thickness through the centre, and are held in the chuck in the manner indicated by Fig. 2, which represents an end view of the chuck, showing the jaws with circles of different sizes, representing the different sized drills in place, the smaller drill being of the same thickness through the centre of the shank, and having correspondingly shallow grooves. It will be seen that the drill is thus driven positively, and does not depend at all upon the tightness of the grip secured by the jaws, but the largest drills are secured in the chuck, and removed from it after doing the heaviest work, simply by applying the hand to the milled shell of the chuck (Fig. 3), without the use of a wrench. A plate at the bottom of the jaws serves to ensure that the drills shall be inserted to the right depth, and as it is loosely held in position, gives opportunity for the slight springing of the jaws above the end of drill necessary to secure it. The grooves on the drill are milled on both sides simultaneously by special machinery, and are afterwards ground to size while held in a chuck, which grips them by these grooves, so that true drilling is ensured. Only two sizes of chucks are used for the full range of sizes of drills, the smaller chuck taking drills from $\frac{1}{4}$in. to $\frac{3}{4}$in., and the larger size all drills above $\frac{3}{4}$in. The chuck shown is of the smaller size, and its shank is grooved to be driven by the larger chuck, though the shanks of either sized chuck may, of course, be of any desired form to suit the machine in which they are to be used. The makers of these drills and chucks are the Graham Twist Drill Company, of Detroit, Michigan, U.S.A.

THE INSTITUTION OF MECHANICAL ENGINEERS.

An ordinary general meeting of this Institution was held on the 19th inst., at 25, Great George Street, Westminster. The chair was taken by the President, Mr. Joseph Tomlinson. After the usual business connected with the previous meeting, the Secretary read the

Fourth Report of the Research Committee on Friction: Experiments on the Friction of a Pivot Bearing.

These experiments were carried out in the works of Messrs. Simpson & Co., at Pimlico, in July, 1890, under the superintendence of Mr. B. Tower. The bearing employed was 3in. diameter, and flat ended. To obtain the equivalent of any desired load on the bearing the latter was pressed upwards against the footstep by means of an oil press having a plunger 6in. diameter, the pressure being applied through a hard steel conical centre formed on the bottom of a plate carrying the bearing and resting against a piece of hard steel let into the top of the plunger. The oil pressure on the plunger was balanced by means of a piston of the same diameter as the plunger, attached to the upper end of the vertical shaft carrying the footstep and revolving with it. This piston worked in an upper cylinder connected by a pipe with the lower cylinder of the oil press. A small hand pump in connection with an air vessel was used for applying pressure. The circular plate supporting the bearing was formed with a groove in its periphery, in which lay a small chain fastened to the plate and embracing a portion of the circumference, from which it led off to a spring balance indicating the force tending to turn the plate. Lubrication was effected by introducing oil through a hole in the centre of the bearing, and distributing it through two radial grooves extending to within $\frac{1}{16}$in. of the periphery of the bearing surface. It was found in working that the oil was delivered out at the top of the bearing, and an arrangement was made by which it was collected and used over and over again, the apparatus thus acting as a sort of oil pump. Subsequently experiments were made with three and four radial oil grooves, but the friction was in this case found to be from one and a half to twice as great as with only two grooves. The trials were carried out at 50, 128, 194,

A NEW TWIST DRILL.

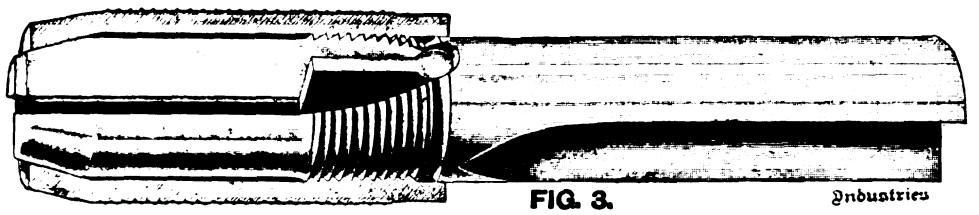

FIG. 3.

290, and 353 revolutions per minute, with various loads on the bearing. The footstep was of steel, and for the majority of experiments the bearing was of manganese bronze, but at one speed a bearing of white metal was also tried. As we shall subsequently publish the report in full, it is unnecessary to refer in detail to the results of the trials; it may, however, be mentioned that at the higher speeds the coefficient of friction is less, and that this is ascribed in the report to the lubrication being more perfect at high than at low speeds, owing to the more rapid circulation of the lubricant. The loads with which the bearings heated and "seized" were also ascertained, and these were found to be from 260lb. to 300lb. per square inch with manganese bronze, and 240lb. per square inch with white metal. The paper was illustrated by diagrams.

Mr. Wicksteed, who opened the discussion, referred in complimentary terms to the design of the machine used in making the experiments, and expressed a hope that such experiments would be proceeded with in the future. A very interesting feature of the apparatus, he considered, was the ram with circular grooves working without packing. The pressure in the ram cylinder was of course not great; the load on the bearing had generally been carried up to about 160lb. per square inch, and this was equivalent to about 40lb. per square inch on the ram; in some cases as much as 240lb. had been applied, equal to 60lb. on the ram. He should be glad to know whether the flow of oil for lubrication increased noticeably at higher pressures; it might be expected that when a certain point was reached the flow would be very copious. He regretted the absence of Mr. Ford Smith, who had carried out trials with a pivot bearing very similar to that shown in the diagrams, but furnished with several discs, with oil circulation round the pivot. Mr. Ford Smith, however, gave the pressure due to the weight of the shaft used by him at 450lb. per square inch, whereas in the report it was stated that the bearings seized at 240lb. It would be interesting to learn what happened at the intermediate pressures between the highest at which the lubrication was recorded as still satisfactory and that at which heating and seizing were observed. Were the resources of engineering exhausted at the latter pressure? He believed not, but that, by using a large number of superimposed discs in the manner adopted by Mr. Ford Smith, the load might be safely increased. It appeared to him that at very low speeds the conditions affecting friction must be very different to those occurring at high speeds. Generally speaking, collar bearings seized at about 80lb. per square inch, but in one case he had found that the collar bearing of a drill spindle bore a pressure of 360lb. before seizing; this was, however, at a low speed, and the construction was such that the oil could flow outwards from the centre, but could not return inwards. It was remarkable what heavy loads were carried on lathe centres without causing seizing. In a large lathe the load carried by one centre was often 10 tons, and, as the area of the bearing surface was certainly not more than 1 square inch, the pressure must be at least 10 tons per square inch. In conclusion, Mr. Wicksteed said that he hoped further experiments would be made with variations in the conditions—for instance, with several discs, with different forms of pivot, and at lower speeds.

Mr. Veitch Wilson pointed out that previous experiments had shown that temperature had very much to do with friction. Had the temperature been noted in the case of the present trials? At different speeds a very considerable difference in temperature would be developed in a short time, and it seemed to him it was important that it should be observed. The influence of temperature on the friction of bearings was the result of the change in the viscosity of the lubricant produced by heating. From tests made by himself, he had found the viscosity of sperm and lard oil at different temperatures to vary as follows:—

Oil.	Temperature.	Viscosity.
Sperm	60°	50
„	120°	30
Lard	60°	100
„	70°	90
„	120°	29

It would be interesting to know whether, in reducing the friction by increasing the speed, power was economised, or whether the work required for producing the heat, which was the cause of the reduction, counterbalanced any advantage of that kind.

Professor A. B. Kennedy remarked that the report was given in a very condensed form, and might, without disadvantage, have been extended to twice its length. He noted that in the first two sets of experiments the coefficient of friction was much higher at the lower speed, while in the subsequent experiments this was not the case. The first trials were made with counted oil drops, while for the later ones continuous lubrication was employed. Did this account for the differences? In order to ascertain with certainty to what such differences were due, it was desirable that the lubrication should be the same at all speeds. It was, of course, quite possible that, apart from the method of lubrication, at low speeds (from 50 to 128 revolutions per minute) the coefficient decreased rapidly with an increase of velocity, while at higher speeds this did not occur. He agreed with Mr. Wicksteed in regard to the use of discs. It would be interesting to know whether the centre of pressure was really situated at $\frac{2}{3}$ of the radius measured from the centre of the bearing, and, if so, whether it remained constantly at this distance. Owing to the unequal velocity of different parts of the bearing surface, the outside would wear first, and this would cause a change in the centre of pressure. It was therefore possible that uniform wear, and not uniform pressure, should be taken into account, and in that case the centre of action would be at $\frac{1}{2}$ the radius. This was, perhaps, more an academical than a practical question, since for practical purposes, provided the assumption with regard to the centre was understood, it did not much matter where it was supposed to be. For narrow ring surfaces it was justifiable to take the radius of the centre of pressure as the mean of the inner and outer radii. With reference to the curves shown on Diagram 5, Professor Kennedy said that they did not represent anything in particular; the actual experimental points ought to have been recorded, and a continuous curve drawn between these, representing as nearly as possible the average results. Perhaps Mr. Tower, who had conducted the trials, would kindly do this by way of supplement.

Mr. Schönheyder said that many people seemed to imagine that a footstep bearing would carry any weight, and in consequence of this it so frequently happened that bearings became hot. A footstep was very much in the nature of a crosshead. Crossheads often worked under a pressure of 600lb. to 800lb. per square inch, but if the oil was wiped away at each stroke 40lb. to 60lb. was more like what should be used. He quite agreed with Professor Kennedy that the friction diminished with increasing speed, and also as to the necessity for a uniform method of lubrication. Mr. Wicksteed's remarks were, he thought, very much to the purpose, but if experiments

Digitized by Google

were made with discs between the pivot and bearing some means would have to be taken for the uniform lubrication of all the discs. The small difference between the results observed with manganese-bronze and white metal was, to him, surprising; he should have anticipated a much greater divergence. The diagrams, in the forms shown, seemed of very little use. What was wanted was not inch-lbs., but the coefficient of friction, and this could not be ascertained directly from the diagrams, but would have to be worked out.

Professor Kennedy here made a supplementary suggestion to the effect that it would be interesting if some account could be added to the report of the experiments made with more than the two radial lubricating grooves.

Mr. Henry Davey considered the construction of bearing adopted a very favourable one. The bearing was carried on a point, and was, therefore, not rigidly fixed; in this particular it differed somewhat from ordinary practice. The heavy weights carried by lathes had always been a great puzzle to him. There was a considerable difference between the conditions occurring in a lathe and those in a footstep bearing. In a lathe nearly the whole load on the centre was carried by the top half of the surface, and this made the puzzle all the greater.

A member inquired if any experiments had been made without oil grooves. He himself had found grooves objectionable, the lubrication being better without them, and the inferiority of the results observed with four grooves to those obtained with two only tended to confirm his opinion. Grooves allowed the oil to escape outwards. Owing to the varying surface speed, and consequent irregular wear, the experiments ought to be continued for long periods in order to arrive at reliable results.

Mr. Lockart suggested that it was questionable whether flat surfaces were the best. Many other forms had been tried. He had himself tried a hemispherical surface working on a flat surface with success. If the pressure were excessive the oil could not get in between the surfaces. Trials ought to be made with discs without grooves.

Mr. G. Cawley, quoting from the paper, said that on page 3 it was stated that "the bearing proved to be a most efficient pump, causing a rapid circulation of oil throughout itself," while further on in the paper was the statement that "the manganese-bronze bearing heated and seized on one occasion with a load of 260lb. per square inch." He would like to ask Mr. Tower whether the pumping action of the bearing was reduced or ceased altogether when the reported seizing took place. As the temperature of a bearing affected the viscosity of the lubricant, he hoped that in future experiments the results would include the temperature of the bearing and viscosity of the lubricant, as well as the speed of the shaft and weight on the bearing per square inch.

Mr. Walker related his experiences in 1852 with an engine driving a large flax mill at Leeds as throwing some light on the subject of the pressure on bearings. This engine had an exceptionally heavy flywheel, and, in order to keep the bearings cool, it was necessary to have men always in attendance to watch them. He was consulted on the matter by the owners of the mill, and, after careful inspection, advised the substitution of a new shaft of good Yorkshire iron in place of that originally supplied, which was of inferior quality, and also that harder metal should be used for the bearings. His recommendations were carried out. Very hard chilled metal was adopted, and the work was executed with the greatest possible accuracy. When first re-started, the journals ran warm in an hour, but a pump for cooling was added, and no further trouble experienced. Engineers, in his opinion, were apt to overlook the great importance of speed and good material and workmanship in relation to the subject of bearings. In the case of lathes, referred to by previous speakers, he believed that hard material, low speed, and careful ubrication accounted for the heavy loads that could be lsafely carried. Generally speaking, he thought the most essential conditions for successful lubrication were good material and workmanship, large surfaces, and low speeds.

Mr. Schönheyder asked what was the load on the flywheel shaft mentioned by Mr. Walker, but Mr. Walker could not state this offhand. He would, however, subsequently furnish particulars.

Mr. Dolby inquired whether during the experiments forming the subject of the report any note was taken of the change in the form of the bearing surface. He further suggested the employment of "Magnolia" metal for the bearing, which, he stated, had been used with very good results on board steamships.

Mr. B. Tower, in replying to the discussion, said that the leakage past the oil ram was very small up to a pressure of 40lb. to 50lb. per square inch, and the arrangement in question could no doubt be successfully used up to a pressure of 100lb. The leakage was easily replaced by an occasional stroke of a hand pump. Mr. Ford Smith's bearing, which he had seen, was no doubt superior to that employed in the trials, but was essentially the same in principle. The intermediate values of the friction, between the highest load given in the tables at which lubrication was satisfactory, and the load at which seizing occurred, were not recorded, as it was necessary, in order to avoid trouble and delay, to be very careful that safe loads were not exceeded. To ensure this and avoid damage the bearing had to be very frequently examined shortly before the seizing point was reached, and accurate observations were thus interfered with. Professor Kennedy had referred to the effect of speed in reducing friction. This he—the speaker—attributed to more perpect lubrication. The rate of lubrication could not be regulated to make it uniform, as suggested by Professor Kennedy, as, with the apparatus used, there was what might be termed a natural rate of lubrication for each speed. Collar bearings were difficult to lubricate efficiently, and this accounted for the small loads they would safely bear. In marine practice the pressure on the collar bearings of screw shafts was generally low. As regarded lathes, he believed that seizing really took place, but that owing to the low speed very little heat was developed. The bearing must in that case actually wear; he could hardly think that with the great pressure exerted the oil could get in between the surfaces. The temperatures developed during the experiments were not recorded, because the subject had been previously thrashed out. Professor Kennedy had raised the question as to the wear of the bearing surface towards the outside, but his own idea was that no metallic wear took place, and that the footstep rested on a film of oil, while the pressure over the surface was uniform. With regard to the diagrams illustrating the results, the curves actually passed through the experimentally recorded points. The fact that the apparatus did not work so efficiently as a lubricator at low speeds would make it desirable in future to use a separate pump for lubrication. He thought that radial grooves were essential for good lubrication. As to the duration of experiments for the purpose of obtaining reliable results, the trials in question had involved working for five weeks, as great difficulty had been found in securing consistent observations; very frequently under apparently the same conditions the results varied widely. The use of a hard steel hemisphere working against a flat steel plate had been tried, but the results were unsatisfactory, and therefore not recorded. The bearing surfaces did not seize owing to a cessation of pumping, but in spite of it. Mr. Walker was quite right in his opinion as to the importance of good workmanship; bearings should have a perfect fit. As a matter of fact, no change of shape did occur in the bearing surface, as was proved by the fact that after the conclusion of the trials the marks of the scraping tools could still be seen here and there. Flat surfaces were adopted because they could be more accurately finished to template than any other forms.

Mr. Schönheyder at this point asked whether the friction of the pivot on which the bearing rested must not be deducted as a minus quantity from the observations.

Mr. Tower replied that this was so, but in the trials it was taken into account by moving the index both ways and taking the mean indication.

Mr. Wicksteed then stated it as his opinion that the use of many discs would not increase the load at which seizing occurred, but that all the discs would seize at once.

Mr. G. Cawley asked Mr. Tower whether, in a bearing with several discs—like that shown by Mr. Ford Smith—he considered all the discs to be in motion at one time, and the velocity of the shaft divided equally between them. For example, in a bearing having four discs, and the shaft running at 300 revolutions per minute, would the mean speed of each disc be 75 revolutions per minute or would only one disc be in action at a time? As the experiments showed that the coefficient of friction was much greater at slow than at high speeds, the supposition that all the discs revolved at once at a fractional speed of the shaft would go to show that the use of such discs increased the friction of the bearing, and that their chief value would be in connection with high speeds, where their action would virtually reduce the speed of the shaft in relation to the bearing surfaces.

Mr. Tower thought that the velocity was not divided up between the various discs, but that the advantage arising from their use was due to the fact that when one disc seized, another came into action, and thus each of the discs in succession had an opportunity of resting and cooling.

Mr. Tomlinson remarked that Mr. Ford Smith, owing to some error, had described his shaft as carrying some load which was ridiculously high. He agreed with Mr. Tower in believing that the discs would seize in succession. If there were no lubricant between the bearing surfaces no weight could be carried. In his long experience with locomotives he had found that not more than 2½ cwt. per square inch could be put upon the bearings without heating, and this value corresponded very well with that obtained in the trials. Mr. Walker, if he went into the matter, would probably find that the pressure on the bearings of the engine mentioned by him was over 300lb. per square inch. Mr. Tomlinson then cited the example of a winding engine in South Wales, the bearings of which had given much trouble, and said that on examination he found this was owing to the bearing surfaces being too small. Collar bearings he considered objectionable, and they nearly always gave trouble. An enormous power was transmitted through the shafts of marine engines, such as those of the "Umbria," and the collar bearing, which had to take the whole of the corresponding thrust, was comparatively so small that it was not surprising if it required close attention. It was no part of the duty of the Research Committee to recommend any particular form of bearing. The flat surface—as Mr. Tower had remarked—was taken simply on account of its being easy to fit accurately.

(To be continued.)

THE MEASUREMENT OF ELECTRIC POWER BY MEANS OF A VOLTMETER.

By J. Swinburne.

There are various well-known methods of measuring alternating powers. The electromagnetic wattmeter and the electrostatic wattmeter I had the honour of describing to the Physical Society are, as far as I know, the only direct reading power measuring instruments. There are various indirect, but accurate methods, such as double reading electrostatic instruments, Joubert's method, and calorimeter tests. There are a few other ways, such as the split dynamometer method, which can measure power only under particular conditions, and lead to erroneous results in such cases as that of a transformer, where the conditions never hold. Electrical powers can, however, also be measured by means of voltmeters.

If the quadrant electrometer connected up as a direct reading wattmeter be analysed, it will be found that the needle forms with each quadrant an idiostatic voltmeter. One quadrant is in connection with the needle, and thus exerts no force, so the instrument is really a combination of three voltmeters. One measures the difference of potential of the ends of the non-inductive resistance, one of the circuit under test, and one of the circuit and non-inductive resistance together. The Blondlot and Curie electrometer acts similarly, but needs two metallic connections, as it has a split needle. A similar result can be obtained by using three instruments.

Suppose the power taken by part of a circuit—for instance, a closed induction coil for testing iron, a transformer, or a condenser—is to be measured, it is put in series with a non-inductive resistance. In Fig. 1 *o a*

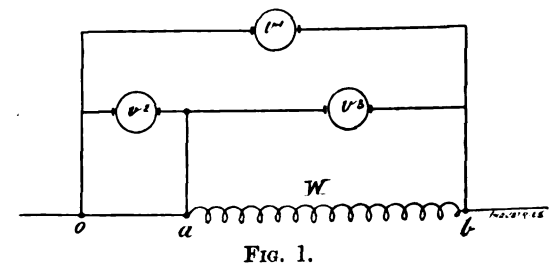

Fig. 1.

is the non-inductive resistance, and *a b* is the choking coil, or whatever is to be tested, which may be called *W*. A voltmeter v^1 is put in shunt to the whole arrangement, and voltmeters v^2 and v^3 are put in shunt to the non-inductive resistance and the work *W*. Let the voltmeters be graduated to read the square of the effective volts. Then, taking *o* as being at zero potential, the instantaneous potential at *a* and *b* may be called *a* and *b*. We then have three instruments. If *t* is half a period

v^1 reads $\frac{1}{t}\int^t b^2\,dt$

v^2 " $\frac{1}{t}\int^t a^2\,dt$

v^3 " $\frac{1}{t}\int^t (b-a)^2\,dt = \frac{1}{t}\int^t b^2\,dt - \frac{2}{t}\int^t ab\,dt + \frac{1}{t}\int^t a^2\,dt.$

Subtract the sum of v^2 and v^3 from v^1 and there remains $\frac{2}{t}\int^t a\,(b-a)\,dt.$

If the non-inductive resistance is *r* the instantaneous electromotive force $a = cr$, *c* being the instantaneous current; so

$$\frac{2}{t}\int^t a\,(b-a)\,dt = \frac{2r}{t}\int^t c\,(b-a)\,dt = 2rp,$$

Digitized by Google

where p is the power supplied to W. Thus, if the resistance is half an ohm, to find the power with three voltmeters, square the reading of each, subtract those of v^2 and v^3 from v^1, and the result is the power in watts. This is independent of any curve of sine hypothesis, and is true whether W is inductive or not.

Interesting as this result is theoretically, it is still more important to find of what practical value it may be. In the first place it has been assumed that the voltmeters themselves take no current. This is practically true of electrostatic voltmeters. One voltmeter may be used with switches to vary the connections. This still means three readings, and as a Blondlot and Curie or my arrangement will read power direct, there is no advance in going back to a three-reading method. It allows those, however, who already possess idiostatic voltmeters to use them for measuring power.

The only other available voltmeter is the Cardew. Three voltmeters are now needed for each, for the instrument takes something like 20 or 30 watts at high readings, and putting it in shunt to different parts of the circuit would introduce large errors in such work as transformer testing. If three voltmeters are used simultaneously, the value of r must be found, taking into account the condition that v^2 is in shunt to it. From the power found, that spent in v^3 must be deducted.

This necessitates a knowledge of the variation of resistance of the voltmeter throughout its scale. The cost of three voltmeters, the trouble of calibrating them thoroughly throughout the scale, both for electromotive force and resistance, renders the method rather unpractical, more especially as the resistance does not depend on the reading of the voltmeter, but on the temperature of the whole instrument, which depends on what it has been doing. For testing very large transformers, however, which have losses enormously greater than that of the voltmeter, or, at least, so great that the errors are inappreciable, the method will, I hope, be valuable. The substitution of equivalent resistances also leads to temperature errors.

There is still another method of measuring power, which I understand has been invented by Dr. Sumpner and Professor Ayrton, who have communicated it to the Royal Society. If it should turn out to be the same as this, however, they should have credit for priority, especially as regards the use of the ordinary voltmeter for measuring power.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

I.

By the term "soap" is usually meant a compound of a fatty acid with an alkali, although, strictly speaking, it is equally applicable to all salts which are formed by the combination of a fatty acid with a metallic base. Thus, we have metallic soaps in which lead, copper, calcium, or iron act as the base. A lead soap (lead oleate, $Pb(C_{18}H_{33}O_2)_2$) is, under the name of "Emplastum Plumbi," used in pharmacy, but only the soaps of the alkali metals are soluble in water, and consequently applicable for washing or cleansing purposes.

The formation of soap can be most simply shown in the combination of a fatty acid, such as stearic acid, with caustic soda or potash, by the following equation :—

$$\underset{\text{Stearic acid}}{C_{18}H_{36}O_2} + \underset{\text{Caustic soda}}{NaHo} = \underset{\text{Sodium stearate (soap)}}{NaC_{18}H_{35}O_2} + \underset{\text{Water.}}{H_2O}$$

The reaction which generally occurs in the manufacture of soap is, however, somewhat more complicated than the above, inasmuch as the fatty acids do not occur as such (except to a small extent) in the neutral oils and fats commonly used by the soapmaker, but are combined with and replace a part of glycerine, in the form of glycerides. For instance, tallow is composed largely of the glyceride tristearin, or glycerine tristearate, which may be regarded as glycerine in which three hydrogen atoms are replaced by three molecules of the radicle $C_{18}H_{35}O$ of stearic acid :—

$$\underset{\text{Glycerine.}}{\left.\begin{matrix}C_3H_5\\H_3\end{matrix}\right\}O_3} \qquad \underset{\text{Glycerine tristearate.}}{\left.\begin{matrix}C_3H_5\\3(C_{18}H_{35}O)\end{matrix}\right\}O_3}$$

Thus, in the saponification of a neutral oil or fat consisting of tristearin, the reaction with caustic soda would be as follows :—

$$\underset{\text{Tristearin}}{\left.\begin{matrix}C_3H_5\\3(C_{18}H_{35}O)\end{matrix}\right\}O_3} + \underset{\text{Caustic soda}}{3NaHO} = \underset{\text{Sodium stearate (soap)}}{3(NaC_{18}H_{35}O_2)} + \underset{\text{Glycerine.}}{\left.\begin{matrix}C_3H_5\\H_3\end{matrix}\right\}O_3}$$

A few years ago the whole of the glycerine, so produced by the saponification of neutral oils and fats, was thrown away as being useless, but this valuable substance is now almost invariably recovered from the waste liquids of the soapworks, and sold for the manufacture of nitroglycerine and for numerous other purposes.

The alkalies used as bases for the manufacture of ordinary soaps are soda and potash, either separately or in conjunction with each other. Soaps made exclusively from soda are usually hard, solid, and opaque, and contain less water than those made from potash, which are generally soft, transparent, and deliquescent. The hardness of soda soaps is also greater or less, as the original oil or fat consisted more largely of the glycerides of stearic or of oleic acid. Both soda and potash soaps are readily soluble in water and alcohol, but are insoluble in ether and petroleum spirit. Moderately concentrated hot solutions, on cooling, solidify to a jelly, which is opaque when water is the solvent, more or less transparent when alcohol is used, and forms in the latter case the jelly called "opodeldoc." When largely diluted with water, the neutral soap is decomposed to some extent, forming an acid soap and liberating free alkali, which, by combining with and removing oily or greasy matters, plays an important part in the operation of washing. The acid soap, being practically insoluble in cold water, is thrown down as a curdy precipitate.

The extent to which soaps are decomposed, and the amount of alkali thereby set free by a given quantity of water, has been investigated by Wright and Thompson, from whose results it appears that the amount of alkali liberated from soaps made from cocoanut, cottonseed, palm, and some other oils, is considerably greater than that liberated from tallow soap. The presence of free alkali in the sample, however, has the effect of preventing the hydrolysis in a marked degree, and so lessons the quantity of alkali liberated by the given amount of water.

Both soda and potash soaps are precipitated from their solutions by strong solutions of alkali, and the former are insoluble in a concentrated solution of sodium chloride or common salt, the addition of this substance throwing the soap out of solution in water, an important property which is made use of in the fabrication of hard soda soaps, to separate them from the glycerine, excess of water, &c. Potash soaps cannot, however, be separated from solution by the corresponding potassium salt, whilst, on the other hand, sodium chloride reacts chemically therewith, forming a soda soap and potassium chloride. Soaps made from cocoanut or palmnut oil require more salt to precipitate them from solution than do those made from other oils or fats, as the sodium salt of lauric acid, which forms the principal constituent of these oils, is somewhat soluble in brine, and hence cocoanut and palmnut oil soaps are largely used at sea, under the name of "marine soap."

Materials.—The materials used in the manufacture of soap, of one kind or another, are extremely various, there being hardly any form of animal or vegetable oil or grease which has not been, or cannot be, so employed. A detailed description of even a few of these is beyond the scope of these articles, but among the more important may be mentioned tallow, lard, palm oil—of which large quantities are now used—palm-kernel, cocoanut, cottonseed, linseed, and castor oils; besides rosin, bone fat, kitchen grease, and free fatty acids, such as oleic acid, obtained from candle works, or recovered from various kinds of waste liquors. Tallow is largely employed in conjunction with rosin for the manufacture of hard yellow soap, although it is now, to some extent, superseded by palm oil. This oil, which is obtained from the outer fleshy coating of the fruit of several species of palm, consists principally of tripalmitin and triolein, and when brought to this country has a colour ranging from dark yellow to deep red. It also varies enormously in quality, the oil from some localities containing not more than 1 or 2 per cent. of impurities, whilst other samples sometimes contain as much as 30 per cent. or more of dirt and water. Samples of palm oil should therefore always be submitted to analysis before purchasing. A certain amount of crude oil—called "red oil"—is used along with bone fat and other forms of dark grease, for the manufacture of brown soap; but the bulk of it is bleached, and employed as a substitute for tallow, in making ordinary pale and mottled soaps. A method of bleaching commonly employed is to treat the oil (previously melted and decanted from dirt) with a mixture of potassium bichromate and hydrochloric acid in wooden vessels. The oil is at the same time agitated and rapidly becomes black, changing to green, while a froth forms on the surface, showing the end of the reaction. Palm oil, bleached in this way, is white, with a greenish tinge, due to traces of chromic oxide, and has the consistency of fairly hard tallow. Palm-nut or palm-kernel oil, derived from the kernel of palm nuts, is, at ordinary temperatures, a white solid oil, very similar in appearance and character to cocoanut oil, and, like the latter, consisting largely of the glycerides of lower fatty acids. Linseed and hempseed oils are employed only in the making of soft soap, along with cottonseed and other oils. Large quantities of cottonseed oil are also used in the manufacture of hard soda soaps, while castor oil is generally converted into transparent soap.

The character of the water employed in a soapery is a matter of some importance; soft water, free from suspended impurities, being almost a necessity. If hard water be used, the salts of calcium and magnesium present therein, and constituting the hardness, combine with the fatty acids, forming insoluble calcium and magnesium soaps. Where only very hard water can be obtained, and the hardness is due to the carbonates of calcium and magnesium, it is better to soften it by the Clarke or Porter-Clarke method of agitating with slacked lime, and allowing the precipitated chalk to subside, but of course care must be taken that the lime is not added in excess.

(*To be continued.*)

NOTES ON OILS.

I.

In 1890 those interested in the oil trade had cause to be satisfied with the development of many branches of their business, and the present year has good prospects in both the mineral and seed oil branches. The Scottish Mineral Oil Association has apparently justified the purpose for which it was established, in regulating prices for paraffin oil and wax, and in enabling the Scotch manufacturers to successfully compete against the importation of American and Russian petroleum. Meanwhile we find new sources of "rock oil" being discovered. The Salt Union are engaged in boring for petroleum in Cheshire with good hopes of success. From India comes a confirmation of the discovery of mineral oil in the Shirani country by the Zhob expedition, although the amount is stated to be small. From South Africa, too, we hear of the discovery of bituminous shale in the Silurian formations in the Transvaal, and a report by the Government Analyst of Natal excites hopes of borings being profitable in these deposits.

Amongst recent scientific work connected with mineral oils and petroleum we find a report by Kast and Künkler on the Egyptian petroleum discovered some years ago at Gemsah, on the Red Sea. The general conclusions of the authors point to the crude oil being unsuitable as a source of illuminating oil, but valuable for the manufacture of lubricants. Professor Orton has contributed to the literature relating to the origin and formation of petroleum in a pamphlet on "Limestone as a Source of Petroleum and Inflammable Gas," in which he draws very different conclusions as to its origin to Mr. Peckham and other authorities on this subject. An article by A. Vieth appears in the *Chem. Zeit.* (14, 1368) on the formation of petroleum, in which he supports the results arrived at by Engler as to petroleum being of animal origin, but differs as to the manner in which the fatty acids from the animal matter are decomposed. He considers that of the products of the dissociated fat—viz., glycerine and fatty acids—the former is converted by heat and pressure to acrolein, which by elimination of water and by condensation becomes benzene, whilst the latter under the same circumstances are converted into hydrocarbons and carbon dioxide. This carbon dioxide is reacted upon by the dissociated (liquid or solid) hydrocarbons, with the ultimate formation of gaseous hydrocarbons. Vieth thus comes to the conclusion that when gaseous hydrocarbons are found in petroleum they are formed in the above manner from carbon dioxide, whilst their absence points to the carbonic acid having been utilised for the formation of carbonates.

The Board of Trade returns show an increased importation of American and Russian petroleum for the past year, although its average value has ruled lower—

	1889.		1890.
Gallons	102,647,478	...	104,809,146
Value.....	£2,593,173	...	£2,389,269

In the fixed and seed oil trade the most remarkable feature which presents itself is the enormous increase in the output of American cottonseed oil. In 1888 the value of this trade was comparatively very small. Now, as compared with 1889, it represents an increase of over 400 per cent. :—

	1889.		1890.
Value exported ...	£189,252	...	£794,205

The major portion of the oil comes to England, France, and Germany.

A new use is expected for boiled linseed oil, which may have an important application. The tendency of paints upon ironwork to scale is generally known. It is proposed to coat the iron previous to painting with boiled oil, which removes any irregularities, and presents an even surface to paint on when dry. The results are said to be very satisfactory.

Digitized by Google

E. Gérard has recently announced the discovery of a new fatty acid in the oil from ordinary thorn-apple—*Datura oliamonium*. By saponification with litharge, linoleates and oleates are obtained soluble in ether; the residue contains lead palmitate and the lead soap of the new acid. These are separated by fractional precipitation with barium acetate. The new acid melts at 55° C., and the author proposes to call it "daturic acid," assigning to it the formula $C_{17}H_{34}O_2$. This would place it between stearic and palmitic acids, though it has a melting point considerably lower than either. Fatty acids said to be of this composition have been previously described, but they differ in melting points. One described by Becker in 1857 melted at 52° C. Heintz soon after isolated one melting at 60°, whilst Krafft in 1879 also described a similar fatty acid whose melting point was 60°. A recent paper by Dr. Unger, in the *Pharm. Zeit.*, contains the results of some experiments on the alteration of cod-liver oil with age, from which it appears that the free acidity of the oil is slowly increased by keeping. He reports very favourably on the oils yielded by the 1890 fishery, and contrasts them with the 1889 supply, which was of inferior quality.

MODERN CHEMISTRY IN ITS RELATION TO SANITATION.

Dr. Tidy, in his third and concluding lecture, first discussed the means of disinfection best adapted to the sick room. It is important in this connection to bear in mind that the air of a room can only be efficiently disinfected by a gaseous or volatile disinfectant, and that therefore Condy's fluid — being a non-volatile compound—is useless for this purpose. If the patient has been removed, all draperies and wall paper should be burnt, and of the gaseous disinfectants sulphurous acid is, perhaps, the most economical and reliable to employ. Notwithstanding Koch's latest experiments, which show that the anthrax bacillus is not killed by the action of this gas even after twenty-four hours' exposure to its influence, the ancient reputation of sulphurous acid as a disinfectant seems to be well merited. From Homer's time it has been used for fumigation and disinfecting purposes with very beneficial effects, and its well-known effects upon plant life and for destroying germents cannot be ignored. The halogens also rank as valuable gaseous disinfectants, but here, again, it is noteworthy that the conditions of success must be carefully considered. Chlorine acts as a disinfectant in the same way as it bleaches—*i.e.*, moisture must necessarily be present. An atmosphere containing 50 per cent. of dry chlorine has no action upon the anthrax bacillus, whilst 4 per cent. in a moist air kills in half an hour. The activity of chlorine thus depends more on the extent of moisture saturation than on the quantity of chlorine present. Bromine is likewise a good disinfectant, but has the disadvantages of being expensive and exceedingly difficult to manage. When sulphurous acid is employed a convenient rule to observe is to use 1½oz. of sulphur per 100 cubic feet of air space to be disinfected, and with chlorine, being a heavy gas, it is important to liberate it not far below the ceiling, so as to ensure its rapid admixture with the air of the room.

For the floors and articles that can be washed lime and alkaline soaps are to be recommended, as recent work has clearly established that alkalinity is a true germicide. All the alkalies, lime, and baryta have a disinfecting action equivalent to their alkalinity value. Carbolic acid is of much repute, but it usually acts by arresting the growth of bacteria, and by preventing spores from becoming active. One part per 1,000 is sufficient for this purpose, but a 1 per cent. solution is required to destroy the organisms, and a 5 per cent. solution may not kill the spores, even after twenty-four hours' exposure. The solid and pure acid when dissolved in alcohol yields a stronger solution than can be obtained by the use of water, but it does not appear to have any greater value as a disinfectant. In fact, a dilute solution in water is the best form of this reagent to employ. Carbolic acid, according to Dr. Tidy, has been overvalued as a disinfectant.

When a sick person cannot be removed from the room, volatile oils, scents, and camphor may be employed, as most of these bodies, by slow oxidation, under the influence of light, cause the production of ozone, which, as has already been seen, is one of nature's most powerful disinfecting agents. An alcoholic solution of thymol was found to have no action upon anthrax bacillus, but when diluted with thirty times its bulk of water it was exceedingly active. In the form of spray this dilute thymol solution forms a convenient disinfectant for the air of a sick room, and if plenty of ventilation also accompany its use leaves little to be desired. Sawdust, impregnated with carbolic acid, may also be used, if the sawdust be re-saturated with the acid every day. Garments and linen may be washed in a dilute solution of Condy's fluid, but everything that can be burnt should be destroyed.

Dry hot air has been recommended for the disinfection of bedding, but a short exposure to its action is useless, and a longer time is destructive to the material. Steam is a far better agent to employ in the disinfecting chamber, Koch having demonstrated that steam under pressure destroys the most resistant of spores in less than one hour. Even steam under atmospheric pressure can be relied upon if the duration of the exposure to its action be allowed for three hours.

In conclusion, Dr. Tidy pointed out that the real difficulties in this subject were due to the fact that we know so little, and that the gaps in our knowledge are at present so wide, that mankind must be content to wait before the complete solution of these problems can be arrived at.

Notes.

EXHIBITION AT SAN PAULO.

An International Exhibition is to be held at San Paulo, Brazil, in January, 1892. Full particulars can be obtained by intending exhibitors by applying to the Secretary of the French Chamber of Commerce at Rio de Janeiro, Brazil.

INTERNATIONAL ELECTRICAL EXHIBITION AT TOULOUSE.

An International Electrical Exhibition will be held at Toulouse during the present year. The Exhibition will be open for a period of four months, from the 15th May to September 15th next, and will comprise the following sections:—Electricity and Electric Lighting; Electricity as applied to Engineering; Industrial and Commercial Chemistry; Hygiene. Full particulars may be obtained by applying to the secretary of the Exhibition at Toulouse.

JAPANESE COAL FOR STEAMSHIPS.

From reports which have reached us recently, it would appear that some kinds of Japanese coal are well suited for steamship requirements. That obtained from the Miike mines, owned by Messrs. Mitsui & Co., is now largely used in steamers calling at the Chinese and Japanese ports. One large shipping firm report very favourably of this coal. In referring to it they state: "Our ships used it on several occasions when in China and Japan, and the captains and engineers reported most favourably as to its steaming power and the quantity burnt per diem. In fact, they considered it almost equal to the best Welsh coal."

ALKALI MANUFACTURE IN RUSSIA.

The Russian Chemical Society has recently received a sample of the first output of Russian bleaching powder from P. K. Ushkoff, of Elabouga, in the province of Viatka, who has started manufacturing bleaching powder on a large scale from native products. This is considered a very important step in the growth of Russian chemical industry, as the whole of the bleaching powder hitherto required for home industries had been imported from abroad (about 10,000 tons per annum). The same manufacturer has nearly completed his arrangements for manufacturing soda ash and caustic soda by the Leblanc process.

AGRICULTURAL EDUCATION IN WURTEMBURG.

The agricultural education of the people is by no means neglected in Wurtemburg, being cared for by numerous schools and societies, and appears to be fully appreciated by the peasants and others. Almost every institution of this sort had greater demands made upon it in 1889 than in the previous year. To enumerate briefly some of the most important:—The Agricultural and Gardening School had its normal number of students. The School of Vineyards, in consequence of increasing demands for tuition in this branch, was again forced to exceed its statutory number of pupils. The Agricultural Winter School was attended by 103 scholars, being an increase of six on the previous year. A sixth school was added to the five already in existence for teaching country girls and young women farmhouse and dairy work. The travelling teachers of husbandry, as well as those specially devoted to orchards and vineyards, were in great request amongst local societies and by the communal authorities. Sixty-four students attended the lectures upon orchard cultivation. Ninety-two farriers were taught at the various veterinary colleges and schools throughout the country. The winter evening agricultural schools, reading clubs, and local libraries all showed a considerable increase both in numbers and in attendance. Altogether some 23,400 persons attended agricultural schools or lectures on husbandry during the year. This is rather more than 1 per cent. of the total population of the country, and is good evidence that the people as a rule do not neglect the opportunities given them of becoming successful agriculturists.

PROGRESS OF THE BENARES WATERWORKS.

In the report of Mr. Wilson, the resident engineer, for December, it is stated that the earthwork of the embankment and excavation of the settling tanks have been nearly completed. The water in Nuneriah-pokhra having been exhausted, the steam pump has been removed to Sankhudharra tank. The laying of the pipes of the rising main from the Ganges has now been commenced, and when these have been laid an ample supply of water for the works at the distributing station will be obtained. The concreting and brickwork of the tanks is now in hand, and arrangements have been made for stone ballast for the concreting, as being superior to brick ballast. In filter No. 1 about 20 per cent. of excavation has been done; in filter No. 2, concreting under main walls and central drain is completed; in Nos. 3 and 4, about 90 per cent. of excavation is finished; in No. 5, concreting under main walls and drain is completed, and about 2ft. of brickwork in main walls and the central drain built; in No. 6, concreting under main walls and drains completed, and brickworks on three sides of main walls in progress; No. 7, concreting under main walls is completed, and about 3ft. of brick ventilators is being fixed. In the reservoir some 600,000 cubic feet have, according to the *Indian Engineer*, been excavated to an average depth of 10ft. Pipes of different diameters are arriving in large quantities daily, and have been delivered at the distributing station and along the rising main. The land for this latter between Bhadaini and the distributing station has been made over by the civil authorities, and the laying of the 24in. pipes has been taken in hand at the unfiltered water pumping station at Bhadaini. The work of clearing the site has made good progress, and the contractors have promised to shortly deliver a wrought-iron well kerb of 26ft. 8in. diameter on the suction well.

THE NEW WET DOCK AT BOMBAY.

The new dock will occupy the old Customs Basin at the northern extremity of the Government Dockyard, and in order to enable the work to be commenced the contractors, Messrs. Bulkley & Co., recently began to raise a dam between the dockyard quay and the Customs Bunder to close the communication between the basin and the harbour proper. To secure a complete enclosure of the site selected for the new dock it was, of course, necessary to raise the huge earthern dam in question; and for the purpose of its construction no fewer than between 30,000 and 40,000 cubic yards of ballast and stones had to be provided. The Island of Elephanta, states the *Indian Engineer*, was chosen as being best able to supply the requisite material, and during the past two months a fleet of something like fifty country boats of various descriptions have been kept constantly plying day by day between the dockyard and Elephanta to convey it, while not less than about 1,500 men have been engaged in loading and discharging it. No. 1 dam is completed. This dam completely shuts out the sea both from the old Custom House Basin and the Duncan Graving Dock, and as soon as the few feet of water at present lying in the basin have been pumped out, the floor of the new dock, which will monopolise some five acres of ground, will be excavated to a depth sufficient to easily accommodate the largest of the Royal Navy vessels that frequent Bombay and the ships of the Indian marine. Advantage is also to be taken to lengthen and deepen the Duncan Dock to enable it to take in the Indian troopers and ships of the Royal Navy, both docks being exclusively for the use of Government and the Indian marine. The scheme of improvement, however, does not end here, for a second dam is shortly to be raised, which is to exclude the water from the works for an improved wet basin for the joint use of the Arsenal and the Port Trust. This will be constructed in close proximity to the Customs Bunder. The cost of the new wet dock and the improvement of the Duncan dock is estimated at about thirteen lakhs of rupees, and the time allowed Messrs. Bulkley & Co. for the completion of the entire work is two years from the 16th of December last, but the contractors are hopeful of getting it finished at a considerably earlier date.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

9th March, 1891.

4159. Bayly, J. P. ..... Draught appliance for locomotive engines (*Lindsley*).
4164. Lea, J. ..... Typewriting machines.
4165. Lindemann, O. ..... Water jet condensers.
4172. Eastwood, S. ..... Carding machines.
4173. McIntyre, R. ..... Apparatus for welding furnace shells for steam boilers.
4174. Scott & Scott..... Steam boiler furnaces.
4193. Schutte, G., Jun..... Steering gear for torpedo steamers.
4208. Hooper-Rastrick, R. J. Evaporating apparatus.
